THE FIRST BOOK.

LIBRARY INSTITUTE

Chap. 1. *Of Philosophy in General.*

THe words *Sophia* and *Philosophia*, are of kin one to another; the former being of more Ancient use then the latter. For those Men who were by the French termed *Druides*; by the Ægyptians, *Priests*; by the Persians, *Magi*; by the Indians, *Gymnosophists*, *Brachmans* and *Samanei*; being persons wholly emploied in the Inquisition of Truth, and reputed to excell all others in the knowledg of great and excellent things: they, by the Ancient Greeks were termed *Sophoi* and *Sophistai*, that is to say Wise-men or Sages.

And, Because this Title, seemed in it self, too much savoring of Arrogance; and many men void of all true Wisdome, did for gaine or honors sake, make profession thereof, terming themselves *Sophous* and *Sophistas*, that is to say, Wise Men or Sages: *Pythagoras*, both to avoid the Arrogance of that Title (for God alone is truly wise) and to distinguish himself from such men as were wise only in Name, also to declare that Wisdom is no common thing nor within the reach of every Man; was the first that changed this Name, refusing to be called *Sophos*, that is to say a Wiseman or Sage, and choosing in stead thereof the Title of *Philosophos*, a Phylosopher, or Lover of Wisedom; as we find it recorded by *Cicero* in the first Book of his *Tusculans* Questions, and by *Plutarch* in his Third Book of the Opinions of Phylosophers, Chap. 3. *The terme Phylosophy whence derived.*

The Novelty of this modest Title was so pleasing to learned Men of all Sects, that they chose all by common consent to be called Phylosophers, Lovers of Wisedom, rather then *Sophoi* or *Sophistai*, Wisemen or Sages. So that, if we consider the Original of the word, *Sapientia* and *Phylosophia*, Wisedom and Phylosophy, are of one and the same import.

Howbeit, The Word *Sapientia*, is commonly taken in a more strickt sence, so as to signifie the Metaphysicks, as being reputed the most sublime and excellent of all Theoretick Sciences and consequently termed *Prote Sophia*, the principal part of Wisedom, and *Prote Phylosophia*, the most excellent Phylosophy. Whereas on the contrary side, the same word *Sapientia* or Wisedom is used in a larger sence by *Aristotle* in the sixth Book of his *Ethicks* written to *Nichomachus*, Chapter, 7. where it is attributed unto Artificers and *Phydias* a carver in stone and *Polycletus* a maker of Statues, are termed *Sapientes* or wise Men.

But as the word Phylosophy is sufficiently known to all men; so are there very few that understand the true definition of the thing it self. For those main Definitions thereof, which go up and down among learned Men, are rather descriptions and *Encomiums*, then right Definitions. *Plato* describing the same in his *Dialogue* termed *Phædo*, calls it *The contemplation of Death*. For, there being a twofold kind of Death, the one natural, which is a Separation of the Soul and Body; and the other such a Death as whereby the Soul continuing in the Body, is weaned from Earthly things, abandons vitious desires, and gives it self wholly up to the Contemplation of the most Excellent Objects: and seeing Phylosophy teacheth, this same Abstraction and Separation of the Soul from the Body, which is as it were the Prison thereof, and the Garment of Ignorance, whereby it is clouded; therefore *Plato* *Plato his Definition of Phylosophy.*

(though Metaphorically and therefore not so fitly) defines it to be, *The Meditation of Death.* In the same sence, it is said to be *The Separation of the soul from the Body, And Affectation of Death,* and a *Customary course of Dying daily.* And the same *Plato* in his Dialogue termed *Theætetus* saies that *Phylosophy, is to study as much as may be to be like God.* For the Operations of God being of two kinds, *Viz.* The knowledg of all things, and that Action whereby he Rules and Disposes all: Phylosophy makes a man capable of both these as far as human Nature is capable. For she both teaches us to contemplate all things, and to guide our Actions by the Rules of Honor and Honesty.

Cicero his Definition. That also is a common Definition of Philosophy which was used by the *Stoicks* and by *Tully* in the Second Book of his Offices, Viz. That *Philosophy is the knowledg of all things divine and human.* By human things understanding all things corporeal and subject to our sences; and by things divine, meaning all such things as being incorporeal are not subject to our senses, but perceptible only by the understanding. Or by the term human, such things may be understood, as tend to the Preservation and Progagation of this mortal life and civil society of mankind; and by the term divine such sublime matters as transcend vulgar Capacities.

Aristotles Definition. There are also certain definitions of Phylosophy extant in the writings of *Aristotle*, as where in the first Book of his *Metaphysicks*, Chap. 1. he saies, it is the *Science of Truth*; and in another place (though this seems to be intended by him, as a definition of *Metaphysicks* only) he saies that, *Phylosophy is the knowledg of all things that are, not particularly, but generally considered.*

Phylosophy cannot be exactly defined. Nevertheless, as we said before, these are not right definitions, but either *Encomiums* or *Laudatory Elogies*, or Tolerable descriptions, not containing the true kind nor the difference of the thing defined. Yea and the very truth is Phylosophy cannot be exactly defined because it is not *Genus Univocum*, and has a nature distinct from its parts. Neither is it *Homonymal* (for the parts thereof agree more then barely in name) but such an one as they term *Ab uno ad unum.* For we must not think that Phylosophy is some one science conversant about some peculiar sort of being: but that it is the totall kind, comprehending all the Sciences in the world. For all things cannot be known by one habit of the mind, but by divers: which when they are all conjoyned, they make that perfection of knowledg, which is called Phylosophy. And therefore all the definitions of Phylosophy which are usually brought, do swerve from the perfect Law of a Definition.

Its Definition. Howbeit from what has been already said, we may collect this following description: *Phylosophy is an Habit of the Understanding, consisting in Wisdom and Prudence, as that which contemplates all things, and so guides the actions of a Man, as that he may attain the Summum bonum, or cheif Felicity of which he is in this Life capable.* For seeing a Man is perfected by Phylosophy, and thereby qualified, it must needs be a certain quality or accidental form, by which a man is made fit to perform all the actions and Duties belonging to the human Nature. And it is such a kind of quality as is not born with us (for no man is borne a Phylosopher) but attained, being no other then an habitual ability, not of the body (for it is not the body of a man but his mind which wants perfection) but of the understanding. And therefore Phylosophy is defined to be a twofold Habit of the understanding, viz. Wisdom and Prudence, under which terms Intellection and science are comprehended.

The Division of Phylosophy according to the Stoicks. We are now to consider how Phylosophy ought to be divided into its parts; which is a thing wherein Authors are not agreed. The Stoicks have divided Phylosophy, into natural, moral and rational; under natural Phylosophy, taking the phrase in a large sence, they comprehend not only Physica or the Doctrine of Nature, properly so called, but also Metaphysicks and Mathematicks: by moral Phylosophy they understand that Doctrine which regulates the manners and actions of men; and by rational Phylosophy or Logick that which teaches us how to reason, argue, and find out the truth. And the truth of this division, they thus endeavor to prove. Seeing the happiness of a man, which Phylosophy aims at, does consist partly in the actions of virtue, and partly in the contemplation of truth, hence two parts of Phylosophy arise; the one of which instructs our Manners and actions according to the Rules of virtue, and is termed Moral Phylosophy; the other is busied in the inquisition of truth and hunting out the secret mysteries of Nature, and is termed Physica, or natural Phylosophy. And because in the search of Truth, we are very apt to mistake, a third part is necessary, to teach us the way and method of reasoning; which from *Logos*, reason, is called Logick, Logick, or the Art of Reasoning.

But

But this Division of Phylosophy, is by very many and those very learned interpreters of the peripatetick Phylosophy, rejected, both because the word Physica is therein improperly used, and because it makes Logick a part of Phylosophy. For the intent of Phylosophers was, to include in this division such disciplines, as treat about some real kind of being, the knowledg whereof denominates a man to be wise or a Phylosopher, and Logick is no such Discipline. For the Reasons of things are not the subject thereof, because compared to that which truly is, they have some sort of beeing; for in this respect they belong to Metaphysicks; nor because, or in as much as they are framed by the mind of man, for so they belong to natural Phylosophy; but only as instruments, profitable to denote our first conceptions, and such things as truly are. And therefore Logick is not a part of Phylosophy, but the instrument of a Phylosopher, to guide his understanding, being invented not for its own sake, but for the better understanding of all other sciences. Which Aristotle confirmes in the first Book of his Topicks Chap. 9. Where he calls it the Handmaid of Phylosophy, yet my intent is not contentiously to wrangle with any man that shal be of the opinion of *Pererius* in the second Book of his Natural Phylosophy, Chap. 18. viz. That when it is disputed whether Logick be a Science or a part of Phylosophy, the Controversie is rather touching words and the manner of Expression, then the thing it self; some taking the words Phylosophy and Science, in a larger, others in a more press and proper signification.

The same refuted.

whether Logick is a part of Phylosophy

Toletus divided Phylosophy into three parts. Speculative, Active and Factive: taking the ground of his division from that Ignorance which Phylosophy cures in us, which is threefold, either of the Truth, and that part which heales this, teaching us to find out the truth, is called Speculative or contemplative Phylosophy; or it is Ignorance how to act and play our parts upon the stage of this world, and that which cures this, teaching us to conform our Actions to the Rule of right Reason, is called Active Phylosophy; or finally it is the Ignorance of things necessary to maintain and preserve our Lives, and that is healed by the Factive part of Phylosophy, under which is comprehended all curious mechanical Artifices. But, though this division be true in respect of the principal disciplins: yet is it no good division of Phylosophy. For, the *Factive* Disciplines are not to be reckoned as a part of Phylosophy; For, they do neither contemplate things divine; nor do they regulate these actions which are proper to a Man; nor is honesty the thing they aime at, but Profit, nor does the chief good and Felicity of a man consist in them. And who is there that dares reckon Smiths, Carpenters, Joyners, Weavers and such like Artificers, amongst Phylosophers? For they are only the Servants of civil Policy. And therefore Lucian justly derides those, which reckon Arts mechanical as a part of Phylosophy, when speaking of one that was about to dig up a Feild, he saies, that with his Spade he would play the Phylosopher.

The division of Tolet.

The said division refuted.

It is therefore to be observed, that the name of discipline is of larger Extent then that of Phylosophy, and that all Disciplines are not comprehended under the Notion of Phylosophy. Yet has Phylosophy obtained this peculiar dignity, that all disciplines are either a part thereof, or fruits growing and resulting there from; or an instrument provided and fitted for its Service.

The name of discipline larger then of Phylosophy

I, for my part, take that to be the truest division of Phylosophy, which is delivered by *Aristotle* in the Second Book of his *Metaphysicks*, Chap. 1. and retained by all sorts of interpreters, viz. into Speculative and Practical. The Speculative part, is that which contemplates all beings or things, with their Principles and Affections or Qualifications, only for knowledg and truths sake: But the practical part of Phylosophy is that whose subject is the Actions of Men, which it regulates according to the Rule of right reason and Honesty; and does therefore teach us not only to know but to do also. For seeing the mind which Phylosophy is to inform and frame, has two parts, the Intellective or understanding part, and the Appetitive or desiring part, they make a double end, and it makes two parts of Phylosophy; the Speculative, which perfects the knowing or Intellective part of the Soul or mind, and the practical, which moderates the Appetitive part of the mind, and regulates our affections. So that the Duties of a wise man are two, to contemplate all things that are, and to performe such actions as are best, and most suitable to the Life of a man. Or more briefly, to contemplate things divine and regulate human affairs. For, after that (to use the words of *Marsilius Ficinus* in the fourth Book of his Epistles) the Mind of a Phylosopher, has contemplated what is the first good or goodness it self, judging in human affaires, what things are good & what bad what filthy and unseemly, and what honest & comely; what profitable, and what unprofitable: according to the pattern thereof he disposes the affairs of men; draws them from that which

Aristotle his division.

The same confirmed first from the subject

is evil, and by this prudence of governing, he rules his own private Family, and the common-wealth, and teaches the lawes and waies of the Administration thereof. Nor was this division unknown to the Platonicks, For these are the two wings wherewith the mind of man flies up to Heaven, from whence being weighed down with Earthly Cogitations, it had before fallen: concerning which see *Plato* in his Dialogues cald *Phædo* and *Phædrus*, and *Marsilius Ficinus* in the first Book of his Epistles Page, 612.

Secondly the from Object. The Verity of the said division is further demonstrated, from the end and Object. But most immediatly from its end: howbeit distinct Objects do produce distinct ends. For seeing every discipline is conversant about some one thing or other: and there are two kinds of things, as is apparent in *Aristotle* his sixth Book of Ethicks to *Nicomachus*, Chap. 3. Some things being necessary, others contingent, and of those which are necessary, some are simply eternal, ungenerated and uncorrupted; others necessarily made, which though they are not alwaies but are made; yet are they not produced by us; but by nature, working by certaine causes: Now the contingent are such things as may or may not be, and whose principle is in the doer and not in the thing done, which depend upon our will, in the power whereof it is, to effect them or not. Hence we gather, there are two parts of Phylosophy, one which is busied about the things necessary, and the other about things contingent.

Two kinds Of things.

Thirdly from the end. And this distinction of things, does also produce divers Ends. For either we handle a matter, only that we may know it, or that besides the knowledg we may effect the same: a third cannot be assigned. For the things which alwaies are or which are made, but by Nature and not by our selves, we therefore handle, that we may know their nature. For what was ever so made, as to endeavor to effect such things as are only possible for Nature, but impossible for all the Men in the world to effect? But those things which are not alwaies, and may be effected by us, we do not handle only to know them, but that their Nature being discovered we may learn to effect them. And therefore those former disciplines, which are conversant about things, not for any operation, but for knowledg sake alone, are rightly termed speculative sciences, or sciences absolutely and properly so called. But the other disciplines, which are verst in contingent things, or such things as are subject to our will, are called disciplines or sciences (the word science improperly taken) practical and operative.

Object, 1. Nor let any Man here object, that al Sciences and all arts do contemplate and speculate one thing or another, and direct us to the effecting somwhat or other, as Natural Phylosophy leads us to natural magick, the Art of healing Diseases &c. And in Geometry there are many Theorems which teach us to do somwhat, as to Raise a perpendicular upon a right line given. For al Sciences, absolutely, and in respect to their end are contemplative, and respect no action: but the other disciplines, though they are busied also in the knowledg of things: yet they do not subsist therein, but such as are active do thereby govern their actions, and the Factive have only their work made, for their end. Nor does Geometry consider those Theoremes that it may effect any thing; but only that it may contemplate the affections of its subject, and find out the Truth: But the disciplines subject thereunto, do afterwards make use of the said Theoremes, to effect somewhat, Which when they do, they pass the bounds of the higher sciences, as may be seen in Agriculture or Husbandry, and others.

Answer.

Object, 2. Nor let that trouble us which some say, viz. That Contemplation and Action are so nearly combined, that one cannot be separated from the other. And that therefore no true difference can be assigned in this respect, seeing Contemplation it self is an action, and that therefore the sciences while they teach us to speculate, teach us to Act. For every energy or Operation of a Man is not termed Praxis in this Case, but such as is subject to the command of the will, and seeing many Errors may happen there abouts, it needs a certain habit, which being inherent in the practical understanding, should be its rule as it were in acting. Now those Actions which are subject to the will are threefold. One proceeds from the will it self, as Election or choice; a second proceeds indeed from another power, yet is under the command of the will as the Operations of the wrathful and lustful faculties of the Soul: and and touchin; this we cheifly speak in this place. The third of it self, is not subject to the will, but in some respect, as the operations of the speculative understanding,

Answer what Praxis is.

Three sorts of actions subject to the will.

are

are so far subject to the will, as they are performed at this time, and so long or so long, or according to other Circumstances. These therefore, as the former, seeing they are not simply subject to our will, do also not pertaine to this place. We may therefore well grant, that contemplation is an action, that is an act according to the inward energy or operation of the Mind: but no external act, such as that is, in respect whereto, one part of Phylosophy is said to speculate, another to act. For this internal action is no way different from the knowledg of the truth, as in practical Disciplines whose action differs from the knowledg of Truth, and whose end does not rest in the truth known, but besides that, proceeds to work somewhat.

And seeing as has been said before that Phylosophy has more then one single signification; it is to be marked, that this name is attributed principally and primarily to the Speculative part, and consequently and in the second place to the Practical. For they are commonly termed Phylosophers, who apply themselves to the Sciences; and who profess themselves skilful to govern the life of man.

The subdivision of speculative Phylosophy

And this is the general division of Phylosophy: afterwards each part is subdivided. *Aristotle* in the sixth Book of his Metaphysicks Chap. 1. Divides the speculative part of Phylosophy into *Physica*, *Mathematica*, and *Metaphysica*. Which division truly, was both received by the Ancients, and is this day in use, and has its reasons to support it. For since the diversity of Objects breeds a Distinction of sciences, it is manifest that there are no more nor fewer sciences, then the three aforesaid. For a being is considered two waies, Universally and Particularly. That Science which considers the whole and Universal state of Beings as beings, is Metaphysica. The other Sciences consider a being in Particular, and some sort of being. And these are two, as there is a twofold sort of beings. The one is in matter and cannot be known without matter, and this Physica considers: The other is indeed in matter, but it may be separated therefrom by our thought, and may be known distinct from the matter, which is handled by *Mathematica*. And therefore *Metaphysica* considers a being, only as it is a being: *Physica*, considers it as it is moveable or natural: *Mathematica* as it is abstracted from Matter. But, as *Pererius* in the first Book of his *Physica*, Chap. 7. Rightly saies it would not be absurd, if a Man should add a fourth Science, which should treat of spirits and substances separated from matter, which some at this day term *Pneumatica*. Yea it were no Absurdity to add a fift, which should treat of such things as might be naturally known concerning God.

The same demonstrated.

Pneumatica.

Mathematical disciplines divided into pure and mixt.

Again there are several sorts of Mathematical disciplines. For their subject is Quantity; which being double continual and discrete, there wil also be two Sciences purely Mathematical, Arithmetick and Geometry. Musick is subordinate to Arithmetick, from whence it borrows its principles, and considers Number as it is joyned with sound. This according to *Aristotle* in his first Posteriora is two fold, Mathematical and aconstick; but the former is truly and properly a Science, the Latter is rather to be termed an Art. Stereometria which considers the Doctrine of solid bodies is a part of Geometry. Nor is it subordinat to Geometry, because it does not consider Quantity with any Contraction, and addition of matter and sensible quality; nor is it of a middle Nature between *Physica* and Geometria: but purely Mathematical; seeing it quite separates its subject from sensible matter. To Geometry, Perspective is subalternate or subordinate, which considers a line as it is visible: Now Geometry and Stereometry do bring forth Sundry disciplines, which are in some sort of a middle Nature betwixt Mathematical and Physical: yet are they called Mathematical, becaus they use Mathematical principles, and considers all their subjects in relation to quantity. Such are: The Doctrine of the Raine-bowe, Astronomy, Cosmography, Geography, Chorography, Topography. Thence also afterward sundry Mechanical Arts do arise.

The subdivision of Practical Phylosophy

The other part of Phylosophy was the Practical. But Praxis taken in a large sense, comprehends under it *Poiesis* and *Praxis*, properly so called. Now *Praxis* or Action differs from *Poiesis* or working, according to *Aristotle* in the *sixth of his Ethicks to Nicomachus Chap. 4. and the first Book of his Magna Moralia Chap. 35.* In that Action does leave no Work behind it: but Working or *Poiesis* is such an Operation as leaves a work behind it. From this twofold signification of the word Practice, two kinds of disciplines arise, Active disciplines, and Facting disciplines. The factive are the Arts, as was said before, and do not belong to Phylosophy. But

the

the active part of Phyloſophy is divided into *Ethica*, *Politica* and *Oeconomica*.

The utility and neceſſity of Phyloſophy. As to the Utilety of Phyloſophy, though that be cheifly to be regarded in the Practical part: yet has the ſpeculative alſo its profit, of which we read much every where in Authors. Two Teſtimonies ſhall ſuffice in this place. The firſt is that of *Hermes Triſmegiſtus* in his Book Entitled, *Of Piety and Phyloſophy*. *He that is pious and Godly is an exact Phyloſopher. For without Phyloſophy it is impoſſible to be perfectly religious. But he which knowes the things that are, and how they are ordered, and by whom, and for whom: he will give thanks to the cheife workmaſter, as to a good Father, a loving Nurſe and a faithful Steward: And he that gives thanks is Godly; and he that is Godly and Pious, ſhall know, both where the truth is, and what it is, and the more he learnes, the more godly will he grow.* The Second is that of *Scaliger*, in his 307. Exercitation *Sect.* 3. *The Searching into theſe ſubtilities, although it be not profitable to make Windmils or watermils to grind Corn; Yet it ſcoureth off the ruſt of Ignorance from our Minds and whets and prepares it to the knowledg of other things; in a word fills it with ſo much ſplendor, that it can light it ſelf to gain the ſimilitude of the firſt workmaſter: who as he is fully and perfectly all things, and beſides and above all things: ſo he will have thoſe to be his, that are ſtudious of the Sciences; and has made their underſtanding, Lord of all things.*

The pleaſure of Phyloſophy Finally, How great the pleaſure is which ariſes from the knowledg of Phyloſophy and cheifly the Speculative part thereof, *Ariſtotle* teaches in his firſt Book *de Partib. Animal.* Chap. 5. I ſhall here ſet down what *Cæbius Rhodiginus*, *in the ſeventh Book and Chap.* 30. *of his Antiquæ Lectiones*, Cites out of *Maximus Tyrius*. *You know*, ſaith he, *what it is that I think the Speculation of a Phyloſopher does moſt reſemble?* Viz. *A manifeſt, clear and flying dream. For his Body remaining ſafe and ſound, his mind runs al the world over; it is carryed from Earth to Heaven; it paſſes over the whole Ocean Sea; it flyes through the whole Aire; with the Sun it compaſſes the Earth, with the Moon it walkes the round; it joynes it ſelf to the dance of the other ſtars, and comes little ſhort of bearing a ſhare with Jove himſelf, in the Mannagement of all things: O Happy Pilgrimage! O Beautyful ſhewes! O moſt true and real Dreams!*

Chap. 2. *Of the Nature of* Phyſica, *or Natural Phyloſophy.*

SEing we are to treat of Natural things, it is altogether requiſite, that we declare in the firſt place what Diſcipline that is which treates of Natural things, which we cannot do more conveniently then by enquiring into the kind and ſubject (from whence the difference in definition of Sciences is taken) of *Phyſica*, or Natural Phyloſophy.

The Genus or kind of Natural Phyloſophy As to its kind, though ſome do ill in confounding Art and Science; yet all true Phyloſophers and Peripateticks are agreed, that *Phyſica* or Phyloſophy natural, is a Science: ſince the definition of a ſcience does properly agree thereto. For it demonſtrates in a neceſſary ſubject the proper affections by the proper Cauſes: as very many demonſtrations touching things natural, do witneſs. And ſo alſo it is called by *Ariſtotle*, *in the Third of his Phyſicks, Chap.* 4. *Text*, 24. *and the Second of his Metaphyſicks, Chap.* 3. *Text the Third*, and the ſame is by him plainly proved, *in the Fourth of his Metaphyſicks, Chap.* 5. *Text the* 23. And although it be reported that of old, *Heraclitus*, *Cratilus*, and *Pythagoras*, held there was no knowledg of natural things, but only opinion; and *Socrates* being diſcouraged by the Mutability of natural things, and becauſe he thought he had no certain knowledg of them leaving the ſame, gave himſelf wholly to moral Phyloſophy; Alſo *Democritus* complained of the deep pit of truth which had no bottom, and Empedocles of the narrow paſſages of the ſenſes: yet it ſeemes moſt probable that theſe Phyloſophers did not deny all knowledg, but rather modeſtly diſſembled their own knowledg, then confeſſed their Ignorance; ſeeing what we know in compariſon to what we know not, is little more then nothing; and taxed their Arrogance who did vainly boaſt of their own Wiſdome. And as for the new Sect of *Academicks* who did not only deny that there was any knowledg of things natural, but that there was any knowledg of any thing, they are elſe where refuted. Nor let that trouble us, becauſe in natural Phyloſophy many times probable Reaſons are invented. For theſe take not

Whether it be the knowledg of Natural things.

away

away from the neceſſity of the Sciences truth, but do often prepare and fence the way to following demonſtrations, or are uſed to declare the principles.

We muſt therefore hold that *Phyſica* or Natural Phyloſophy is a ſcience and that properly ſo called, viz. A ſpeculative ſcience, as appears out of *the ſixth of* Ariſtotles *Metaphyſicks Chap.* 4. And out of *the firſt of Metaphyſicks Chap.* 6. Although it be in a manner ſuperfluous to ad the term ſpeculative, ſeeing if we take the word Science properly, all Sciences are ſpeculative: now words are not to be improperly uſed in Definitions.

Natural Phyloſophy has two ſorts of propoſitions.

Now as concerning the neceſſary truth of *Phyſica* or Natural Phyloſophy, we muſt obſerve, that there are in this Science two ſorts of Propoſitions; ſome are alwaies and ſimply neceſſary, as the fire burnes: the knowledg whereof is moſt properly called Science: others are neceſſary for the moſt part, concerning ſuch things, as are in their ſubject, only in a certaine ſtate, or for the moſt part, and when all impediments are removed; as a Man is born in the ninth Month, with two hands, two Eyes, two Kidneys. For theſe diſpoſitions are of a middle Nature betwixt contingent and neceſſary, and therefore ſome do call them neceſſary, by a Phyſical or natural Neceſſity.

The ſubject thereof.

Now before we ſpeak of the ſubject of *Phyſick* or Natural Phyloſophy, ſome things are to be premiſed concerning the word ſubject. For this word has ſundry ſignifications. 1. A ſubject is that wherein there are accidents. 2. A ſubject is that part of a propoſition of which ſomwhat is affirmed. 3. The matter is termed a ſubject in reſpect of its forme. 4. A thing is ſaid to be a ſubject in reſpect of ſome Action and Operation; and it is that about which the Artiſt or workman is employed and whereupon he exerciſes his Labor. 5. That is termed a ſubject, which is handled in any Science. Now it is ſo called, becauſe it is ſubjected to ſuch accidents and affections as are demonſtrated therein, as alſo becauſe our knowledg is converſant thereabout. And in this laſt acceptation, we do here take the word ſubject: in which ſence nevertheleſs, it is taken divers waies. For firſt in a more large ſignification, all that is termed ſubject, whereof we treat in any Science, whether it be a principle, an affection and accident, or any other thing. But properly that thing or matter which is therein conſidered is called the ſubject of a Science, which ſubject has theſe Properties. Firſt, That we know that it is in Nature alwaies and neceſſarily, and what the name thereof ſignifies. And therefore the ſubject is never demonſtrated in its proper Science. For ſeeing it is the Baſis and Foundation of all things delivered in the Science, if that ſhal be called into Queſtion, denied, and taken away, all things that are ſaid thereof, are denied and taken away. The Second condition is, that it have proper affections or diſpoſitions, and proper principles, of all which it is the Baſis and Foundation. And therefore a ſubject, in that Science wherein it is a ſubject, is not conſidered as inherent in any other thing; and every thing that is conſidered in any Science, as being inherent in ſome other thing, is not the ſubject of that Science. The third is, that it be adæquate or commenſurate to the whole Science, and not wider or narrower then it, and that all things which are delivered in the Science, do pertain to the Explication thereof. Of a ſubject thus conſidered there are two parts: one is as it were the matter, and is termed the thing conſidered; the other is in ſtead of the form, and is termed the manner of conſidering. The thing conſidered, may be common to many diſciplines: but the manner of conſidering, which contracts the thing to a certain and peculiar way of conſideration, is proper to every Science, and thereupon properly depends the diſtinction of Sciences.

The terme ſubject how many waies uſed?

How underſtood in the place?

The properties of the ſubject of a ſcience

Two parts thereof.

The divers opinions of Phyloſophers about the ſubject of Natural Phyloſophy

Touching this Adæquate ſubject of Natural Phyloſophy, there is ſome difference amongſt authors, moſt of the Greek Interpreters of *Ariſtotle*, do make the ſubject of this Science to be *Corpus Naturale*, a Natural Body; *Thomas Aquinas* ſaies it is *Ens Mobile*, a Moveable being; *Albertus* and *Ægidius* ſay it is *Corpus Mobile*, a moveable Body; *Scotus* wil have it to be, a Natural ſubſtance; *Tolet* makes it, a Natural Being; others ſay it is Nature, by nature underſtanding God and Angels and al Bodies, others again wil have it to be nature, meaning thereby al things pertaining to natural Bodies ſuch asare not only the compound bodies themſelves, but alſo their principles and affections or diſpoſitions: others ſay it is *Ens Mobile*, a moveable being, not only, as *Thomas Aquinas*, underſtanding thereby, a moveable Body, but alſo the matter

and

and forme: others will have it to be *Corpus Naturale Miſtum*, a mixt natural Body: others, a Body ſubject to generation and corruption.

The true opinion. It is not worth the while to produce in this place, all the Arguments that are brought to juſtifie theſe ſeveral opinions. I approve only of the firſt opinion, which ſaies the ſubject of this Science, is a natural Body. To this opinion (as ſhall be ſaid hereafter) I conceive the four following may be reduced; and moſt learned men conceive that the ſtrife is more about words then the thing it ſelf, and that herein lies the controverſie, how the ſubject of this Science, the thing it ſelf being agreed upon, ſhould be called: whether a Natural Body, a moveable being, a Natural ſubſtance, a Natural being: and therefore theſe other opinions are to be reduced to the firſt, or are ſimply to be rejected, as the latter five.

The adæquate ſubject of Phyſick. The adæquate ſubject therefore of Natural Phyloſophy is a natural Body, in as much as it has in it Nature, that is to ſay a principle of motion and reſt. For Natural is taken three waies. Firſt, For that which is eſſential to any thing, and belongs to the very eſſence or being thereof: Secondly, For every thing which concernes the knowledg of Nature; in which ſenſe, both the firſt matter and form and accidents of a Natural Body, are termed Natural: Thirdly, And properly it is taken for that which has Nature in it, that is to ſay, a certain internal principle of motion and reſt; and ſo neither motion, nor matter is termed Natural, but only Bodies compounded of matter and forme. And ſeeing the Adæquate ſubject of a Science, as was ſaid before, conſiſts in the thing conſidered, and the manner of conſidering the ſame: the thing conſidered in this Science, is a body, and the manner of conſidering is, in as much as it has Nature in it, that is to ſay. A principle of motion and Reſt. For although every Body has in it a principle of motion, and that which has in it a principle of motion is a body; yet in as much as a body may be conſidered, not only as it has in it a principle of motion, but in divers other reſpects: by this conſideration, Natural Phyloſophy is diſtinguiſhed from other diſciplines, which do alſo treat of a Body.

Natural, how many waies underſtood?

Confirmation of the Opinion propounded. And that what has been ſaid touching the ſubject of this Science, is true, may hence appear: in that all the porprieties of the ſubject of a Science do agree hereunto. For it is fore known what it is, and what the name thereof ſignifies, it has its proper principles matter and form; its proper affections as motion, place, time &c. nor is it in this Science, inhærent in any other thing, and it is Adæquate or commenſurate to the whole Science. For all things delivered in Natural Phyloſophy, are either the principles of a natural Body, or its affections, or its kinds and ſorts. The ſame alſo is apparent from *Ariſtotle*. For as to the thing conſidered in this Science. that it is truly ſaid to be a Body, appears from the *Begining of his Second Book of Phyſicks, and his 3. de Cælo Chap. 1. and his firſt de Cælo*: Where he tels us that the Science of Nature is converſant about Bodies, and that it conſiders their principles and affections.

And that the manner of conſidering is, in as much as the ſame Body has nature in it, is apparent from the begining of his Second Book of Phyſicks. For ſeeing all things are diſtinguiſhed from other, by their form; and things natural differ from artificial and non-natural things, becauſe they have the principle of their motion in themſelves, but the other only by accident: doubtleſs, to have in it ſelf a principle of motion, is in ſtead of the form, and the formal reaſon of the ſubject, whereby a Body, the thing conſidered in Natural Phyloſophy, is differenced from all other things. The ſame is confirmed by *Ariſtotle*, in the Second Book of his Phyſicks, *Chap. 7. Text* 70. or 71. Where he ſaies: *What ever things move being themſelves moved, do belong to the conſideration of Natural Phyloſophy &c.* For he teaches, that thoſe things only are conſidered by a Natural Phyloſopher, as his ſubject, which have in themſelves a principle of motion. Howbeit, other things may alſo be conſidered in natural Phyloſophy, which have not in them a principle of motion, but it is as they are principles or Accidents to bodies Natural, but not as the proper ſubject of the Science of Nature. Which is manifeſt from the 73. *of the ſame Book*, where he ſaies, that there are ſome principles Phyſically moving, but not Phyſical; that is to ſay not conſidered as the ſubject of *Phyſica* or natural Phyloſophy, becauſe they have not in themſeles a principle of motion. And this is the true Opinion concerning the ſubject of this Science, to which, as was ſaid, the following four

The Differing opinions Reconciled.

Opinions

Opinions must be reduced, or rejected. For seeing these Opinions contain two manner of considering the subject, the one, as it is moveable; the other, as it is Natural: both of them do signifie, indeed, nothing else, but Nature having in it a principle of motion. For since moveable, may be taken two waies, as for that which hath an aptitude to motion, which is a certain affection of a natural thing; or for that which hath Nature in it, that is matter and forme, or the Principle from whence such aptitude arises: moveable cannot be taken here in the former sense, but only in the latter. Because the passion of a subject cannot be its *Ratio Formalis*, or formal Constitutive consideration; and with its subject it makes a thing which is accidentally one, and is later then its subject, of which it may also be demonstrated. Hence therefore would follow this Absurdity, that the subject, *viz.* A thing moveable, should in its proper Science, be demonstrated by its proper Cause, *viz.* Nature. And therefore, *Moveable* cannot be taken for a passion, but for the reason and essential degree of a Body, from which of it self motion arises. In sense it denotes nothing else, but natural, or that which hath Nature in it. Howbeit, if we shal accurately weigh the matter, the manner of considering is better and righter described by the term Natural, or that which hath Nature, then by the word Moveable. For seeing *Natural* includes both motion and rest, and *Moveable* only motion; the former is commensurate, the latter not. And therefore either we must take *Moveable* for Natural, and that which hath Nature, or we must reject it as less Proper and not commensurate. Since from all which hath been said it appears, that *Natural*, or *in as much as it hath Nature in it*, is the true manner of considering the subject of this Science, therefore by all means we must make the thing considered to be equal thereunto. But if we shal consider all things which are placed in the Predicament of substance, we shall find nothing but *Body* equal thereunto. For what ever hath in it a principle of motion is a Body, And therefore it must needs be, that both Ends or Being, and substance, are taken for a Body, But a Body in as much as it hath Nature in it, is more properly said to be the subject of natural Philosophy, because to have Nature is accidental to *Substance*, and to *Being*, unless they be taken in a prickt sense for a Body. Nor is there such a proportion betwixt *Substance*, *Being*, and *Natural*, as ought of necessity to be, betwixt the thing considered and the manner of consideration. For *A Being* is not said to be Moveable, as it is a *Being*; for so every Being should be Moveable.

Moveable understood two waies.

And if there be any that will not allow their opinion to be thus corrected, and wil endeavor to obtrude upon us, somwhat more common, or more narrow, for the subject of natural Physosophy, they are justly to be reproved. For those that wil have God himself, the Intelligences, and Angels, to be handled in Natural Physosophy, as the subject thereof: truly they do absurdly and unskilfully confound things abstract and simple with bodily things and such as are overwhelmed in matter. For seeing these things are exceedingly different, how can any man assign to them one manner of consideration, which is the thing which makes a Science to be one?

Nor do those men think aright, who make Nature the subject of natural Physosophy; understanding, thereby, both the principles, and affections, and Compounds. For they do not rightly use, neither the word *Subject* nor the word *Nature*. For a subject properly so called, whereof we discourse in this place, is not taken so every thing that is handled in a Science, but for that whose conditions are such, as have been set down before, and which is distinguished from the Principles and Affections. Again, they do ill in confounding *Nature* and *a thing Natural*; which they might easily learn, out of *Aristotles* second Book of Physicks *Chap.* 1. where the Physosopher shews us, how *Nature*, *Natural* and *according to Nature*, differ one from another.

Also we approve not their opinion, who conceive that *Ens Mobile* a *Moveable Being* is to be counted the subject of this Science; and by *Mobile* they understand also the matter and the form. For nothing is called moveable, but that which is the subject of motion: and nothing hath in it a principle of motion but a Body. For matter is not moved of it self, but by accident, *viz.* In as much as, it is a part of that Body which is moved. But if so be whatever hath any relation to motion, should be called movable al things explained in this Science, will be several sorts of its subject, and therefore there will be no Principles, no Affections or adjuncts different therefrom.

And as we have rejected their opinion, who make ſomwhat more common then a Natural Body, to be the ſubject of this Science, ſo can we not agree to them, who wil have the ſubject thereof, to be ſomwhat more narrow. For ſome make the *thing conſidered* to be, a Natural Body tranſitory, or ſubject to mutation: others, a Natural Body mixt. Yet they agree in the manner of conſideration, which both make to be *in as much as it is Movable.* But they *both are* in an Error. As to the thing Conſidered; becauſe the former reject the Heavens; the latter both the Heaven and Elements, from being ſorts of the ſubject, and will allow them to be only Principles thereof. For things muſt be ſo handled and conſidered, as they are conſtituted by Nature, Seeing therefore the Heaven and Elements are ſo produced by Nature, as not only that they ſhould be the Principles of other things, but alſo, that as peculiar ſorts of Bodies, they might compleat the Univerſe: they are to be known and handled both waies. As we ſee *Ariſtotle* hath alſo done; who explained them after the former manner in his Book of Generation and corruption; after the latter in his Books touching the Heavens: in which Books, what ever is ſaid of the Heaven and Elements, is ſaid without any reſpect to mixt Bodies. As to the manner of conſidering, they are both out, in that they make it more large then the thing conſidered. For not only, things mixt and ſubject to mutation, but the Elements alſo are Movable, or have in themſelves a Principle of motion.

The definition of Natural Phyloſophy.

From all the Premiſes, let us at laſt infer; that, *Phyſica* or *Natural Phyloſophy, is the Science of Natural Bodies, or of ſuch as have Nature in them.* Whereof being now to treat, I ſhall chiefly follow that ſame Eagle-Ey'd Phyloſopher *Ariſtotle.* For he did ſo excel in this part of Phyloſophy, that, though ſome do make him inferior to *Plato* in matters divine, (which *Scaliger* nevertheleſs denies again and again in the 365. of his *Exercitations, Sect.* 3. Yet in this Science he will eaſily bear away the Bell. I will ſay nothing of the *Platoniſts,* I ſhal only relate what is reported of *Plato.* For he coming upon a time into his School, and *Ariſtotle* being not there, he cried out, *The Phyloſopher of Truth is abſent.* And another time when he was abſent, he ſaid, *The Mind is not come.* And amongſt the Peripateticks innumerable company of moſt Famous Men and every way moſt learned, Greeks, Arabians, and Latines have handed this Phyloſophy to Poſterity, and ſpent all their lives in explaining the ſame, and acknowledged it alone for the true Phyloſophy, and have judged it worthy of ſo much honor, as never any other Phyloſophers Phyſicks were thought worthy of. In the mean time, I would not detract from the diligence and Induſtry of others, nor would I cal any man from making a more diligent ſearch into the ſecrets of Nature. Thoſe who have gone before us (ſaith *Seneca*) have done much, but they have not done all. There is much work yet remaines, and much there will remain, and he that ſhall be born a thouſand Ages hence wil not want occaſion to add ſomwhat or other. But that Man will do it more eaſily, who, hath known theſe things aforehand: and it is eaſie to add to things invented.

Natural Phyloſophy divided into a common and proper part.

And that I may propound a Summarie of al Natural Phyloſophy, as in a table before your Eyes; you muſt know that *Ariſtotles* Interpreters have fitly divided all this Science into two parts; the former they call *common,* the latter *Proper.* In the firſt we are to treat of the kind it ſelf, *viz.* A Body Natural commonly taken. And of all things appertaining to a Natural Body ſo generally conſidered; which *Ariſtotle* handles in his 8 Books of Natural Phyloſophy cal'd *Peri Phyſices Acroaſews.* In the other, we are to treat of all the ſorts of Natural Bodies; which *Ariſtotle* does in all his other Books of Natural Phyloſophy. Nor is this diviſion without Reaſon.

A Natural body how many waies underſtood?

For, A Natural Body is taken three manner of waies. 1. Only for the common kind, in it ſelf conſidered, without any conſideration of the ſorts. 2. For a Collection only of the ſorts. 3. For both together. *viz.* Both for the common kind, and the Collection of al the ſpecies or ſorts Nor are Natural Bodies only to be conſidered, according to the Proper affections, but alſo according to the common. Nor muſt the common affections, of the kind be attributed to the ſorts, nor muſt ſuch things as are proper to the ſorts, be demonſtrated of the kind. A Body Natural therefore taken in the firſt ſenſe, is the ſubject of the common part; taken in the ſecond ſenſe, of the proper; and in the third, of the whol Science.

We muſt therefore in Natural Phyloſophy, treat in the firſt place of a Body Natural in general, and conſider its principles and common affections, which agree to al Natural Bodies, conſidered as ſuch. And ſeeing a Natural Body is twofold, Simple

and

and compound: we muſt firſt diſcourſe of a ſimple natural Body, and its ſorts, the Heaven and Elements, or of the world as it is a maſs of al ſimples. After the explication of ſimple bodies, muſt follow the Doctrine of a mixt body; and firſt in general, where its principles, viz. The four Elements and its general affections or adjuncts are to be explained. Here therefore we muſt treat of the Elements, and of their qualities, of Action, Mixture, Generation and corruption. Mixt bodies, ſeeing they are twofold, perfectly and imperfectly mixed: in the firſt place we conſider things imperfectly mixed; and then ſuch as are perfectly mixed. And ſeeing things perfectly mixed are either ſimilar or diſſimilar: firſt we muſt treat of a body Homogeneal, perfectly mixed; which is handled by *Ariſtotle* in the fourth of his Meteors. Afterwards the ſeveral ſorts hereof are to be explained, as things dug out of the Ground, Mettals, and al the ſimilary parts which conſtitute Animals and plants. Here therefore we muſt treat of things dug out of the Earth and of Mettals. For other ſimilar mixt things, becauſe they exiſt not by themſelves in nature, but are therefore only, that they may conſtitute Animals and Plants, we muſt not treat of them in any other place, ſave where we diſcourſe of Plants and Living Creatures. And thus far may that part of Natural phyloſophy be extended, which treats of thoſe things which are common to things living, and things liveleſs. And the laſt place we muſt treat of ſuch things as concern only things living: and ſo the whole doctrine of natural Phyloſophy, ſhal end in the Explication of plants and Animals.

Chap. 3. *Of the Principles of Natural things.*

Whether a Principle and Cauſe do differ and how?

ALthough theſe two words *Principle* and *Cauſe*, are oftentimes confounded, yet they are found ſomwhat to differ amongſt Phyloſophers. For a principle is commonly of a larger extent then a cauſe. For al that is termed a *Principle* out of or from which at firſt any thing is, or is made or known; but that a thing may be a cauſe it is neceſſary that it receive its Eſſence therefrom, and depend thereupon. And thus every cauſe indeed, is a principle, but every Principle is not a cauſe. For the term from whence any man ſets upon the way, & the point whence a line flowes, are the Beginnings of a way and a Line, but not the cauſe. But paſſing over the ſundry ſignifications of a principle, let us now treat thereof, as it concurs to the conſtitution and generation of things Natural. In which ſenſe, Principles are by *Ariſtotle* thus defined: *Principles are ſuch things, as are neither made of other things, nor one of another, but all things are made of them.* And ſo there are *three* conditions of Phyſical Principles. *Firſt*, that they be not made of other things. For if they were made of others, they ſhould receive their Eſſence, from the principles of another Nature, and ſo themſelves ſhould not be principles. The *Second*, That they be not one made of another. For if one of them did conſtitute another and were a part of the ſame Eſſence, they ſhould neither be *Firſt* nor *Simple*. The *Third*, that all Natural things be made of them and receive their Eſſence from them.

The number of principles is three.

Now as concerning the number of *Principles* there were ſundry not only Opinions but Dreams alſo of the Ancients, which becauſe they are largly confuted by *Ariſtotle* in the *firſt of his Phyſicks*, and the moſt of them are now vaniſhed: Yea and ſome of them are not ſufficiently underſtood: I ſhal here paſs over all thoſe Opinions, and only undertake to explain that of *Ariſtotle*, as moſt agreeable to truth, who aſſerted only three principles of Natural things, *viz. Matter*, *Forme*, and *Privation*.

Yet this one thing I muſt premiſe, That while I eſtabliſh theſe three principles, I do not exclude that only firſt Principle of all things, *God*, eternal, immortal, only one and indiviſible, from whom and in whom are all things, but my enquiry is only after the firſt Natural principles of all things. For neither does *Ariſtotle* deny that all things have their dependance upon the moſt good and great God; as appears in the firſt Book of his *Metaphyſicks*, *Chap.* 2. Where thus he writes: *For God ſeems to be the Cauſe and principle as it were of all things.* And in the fifth Probleme of the thirtieth Section. *God hath given us two Organs within us, wherewith we make uſe of the Organs that are without: viz. To our Body the Hand, to our Soul, the Mind.*

Now being to ſearch out the number of Natural principles; we will take our beginning

beginning from hence, that *the principles of things are contrary one unto another*: which both all the ancients do seem to grant, and the thing it self argues as much. For those are called principles, which are neither made one of another, nor of any other thing, but all things are made of them. Now such things are prime contraries. For seeing they are first, they are not made of any other: and because they are contraries they are not made one of another, for one contrary cannot change into the substance of another thing which is contrary to it. *Moreover* experience it self does witness; that of all things that are, every thing does not act upon every thing, nor suffer from every thing, nor is every thing made of every thing, unless accidentally; but every thing acts upon its contrary, and suffers from its contrary, is made of its contrary, and dissolved into its contrary; or as *Galen* speaks in his *first Book of Temperaments, Chap.* 2. Every mutation is made by a contrary, and of a contrary, and into a contrary.

Seeing therefore the Principles of things are contrary, they must needs be more than one: for contraries are not one, nor can one thing be contrary to it self. 1 *Phys. Chap.* 6. *Text*, 50. Nor yet can they be infinite. For so should there be no knowledg of Natural things, which depends upon the knowledg of their Principles, and Nature it self abhors infinity. Moreover, since in every kind, there is one first contrariety; and of one contrariety, two extreams: consequently in a substance there are not infinite contrarieties, but those two first and extream are to be held for principles.

Wherefore two first contrary Principles are sufficient: one from which the departure is made, and which is the term from which the other, to which the Progress is made, or the term to which. Howbeit these contraries are not alone sufficient for the constitution of a thing. For as a contrary doth not make its contrary; so they alone of themselves cannot constitute a substance. For that contrary which is induced, cannot be received into that which is expelled; seeing contraries do mutually resist one another; and at the end of the motion, that contrary which is expelled, ceases to be. A third principle therefore of things must be added, which is contrary to neither of the other two, and which one while with one, may constitute one natural thing, another while with the other may constitute another, and which may be the subject of those contraries, by turnes. For seeing in every mutation a subject is required (for an accident cannot be without a subject) as *Aristotle* in *the first of his Physicks Chap.* 7. Proves by Induction; and which in the mutation of accidents, is most of all apparent, wherein we see there is a common subject of the accidental form abolished, and of that which is bred a new: and it is manifest that there is no progress from contrary to contrary, without some subject matter: the same is to be concluded touching that substantial mutation, which happens in a natural body.

And these three principles do suffice. For both one subject is enough to suffer: and two contraies to act. For one contrary can corrupt its contrary. The principles therefore are *Partly* contrary, which are called *Form* and *Privation*: and partly not contrary. For the subject which we call *Matter*, is apt to receive al forms. And they are all three necessary to Generation, which is nothing but a progress from the privation of one form in the matter, to the acquisition of a new form: yet every one after a peculiar manner, *viz.* The form as the *terminus ad quem*, the terme to which the motion is made; Privation, as the terme from which: the Matter, as the subject of the Mutation. Howbeit to the *Constitution* of a thing, two principles are only necessary *viz.* Matter and Form. For privation, besides that it is no substance seeing it is contrary to the form, it cannot consist therewith. Hence *Simplicius upon the first of Aristotles Physicks*, saies, To enquire after the Principles of natural things, is one thing, to enquire into the principles of mutation, is another; for of things natural Privation is an accidental Cause; but of Mutation it is a direct cause, or a cause by it self.

whether there be a Materia prima, or first matter.

These things being thus generally spoken touching the principles of natural things, let us proceed to handle them in particular. And as to the *first Matter*, although that there is such a thing in Nature, was before proved: yet let us prove it again, after this manner. Whatsoever is made, is either made simply of nothing, or of something. Not of nothing, for that is creation and not Generation; and therefore of something, now that of which a thing is generated, is either only form, or the whol compound,

compound, or somwhat besides these. Not the two former. For in the Generation of a new thing the former form perishes. There is therefore somwhat else remaining besides the form in that thing, out of which a new substance is generated, *viz* the matter, which hath a privation of the thing to be generated, and which is apt to receive as well that form which it now actually possesses, as that which, the former being abolished is introduced into its place. Now that this *is the first subject* and depends upon no other, is thus proved. Whatever things are changed, have a common subject. Al these sublunary things are changed one into another; if not al immediatly, yet mediately. For things mutually fight one against another, with contrary qualities, alter one another, and throw one another from their natural state and condition. Therefore they have al a common subject. For if it were of some other thing, it would not be subject to all mutations: and if it were not common, al things could not be changed.

The Doctrine of the first matter is obscure & exceeding hard to be known.

But what is the *Essence* of *Matter* is exceeding hard to find out, and can hardly be discerned by a direct knowledg. For as essential mutation, by which it is demonstrated, that there is matter, was known by way of analogy from accidental mutation; even so by analogy, and a certaine bastard kind of knowledg and inspection (as *Plato* saies) we come to the knowledg of matter. For from the knowledg of sensible matter, we are led to the knowledg of insensible: and so is matter related to form Natural, as Brass or Wood to the Form or Figure of Mercury. For even as Brass or wood, does in it self actually possess no artificial form; yet is it furnished with a power to receive al forms: even so the first matter, hath in it self, no determinate specifick natural forme; yet is it apt to receive all formes, howbeit herein they differ, in that the artificial matter is a body of it self existing and perfect: but the Natural matter doth not exist by it self without the form.

Matter is considered two manner of waies.

Now matter is considered *Two maner of waies*, one absolutely, as it is a beeing or a certain substance: the other, repectively, as it is a principle of natural things. In the first manner of consideration, we say it is void of all formes and Qualities, Dimensions and Quantities, and we allow it a power of receiving indifferently all formes; in which respect *Aristotle* in the *sixth of his Metaphysicks, Chap. 3. Text. 8.* Describes it by the negation of all things. *In the second notion* we attribute unto it a power of receiving particular forms, and privation; in which signification *Aristotle* in the first of his Physicks *Chap. 9. Text. 82.* Defines it, that it is *The first subject of every thing, of which every thing is made, being not accidently inherent, and into which it returnes when it is corrupted.*

The disinition of matter.

The first matter is no notion of the brain.

And although in its first notion, it can very hardly be known, because of its weak and obscure Entitie, by which it comes near to a Non-beeing, and is the lowest of al beeings: yet must we not think that it is a meer fiction of our Brains. For it is undoubtedly a real being, and indeed a substance, as appears in the I. *Of Aristotles Physicks Chap. 6. Text. 52. Chap. 9. Text, 79. In the Second de Anima, Chap. 1. Text. 7. In the Seventh of Metaphysicks, Chap. 2. Text 7.* For of it, and form al natural substances are compounded; and it is the subject of Generation, and receives the formes; and it self is in no other thing or subject. Now by substance, we do not here understand a compound substance, which is properly called substance, *but a being* as it is distinguisht from an accident, and opposed thereunto: which is *two-fold*: *One* in act, as the forme: the *Other* in power, as is the matter. Nor is it an incorporeal but a corporeal substance. For seeing of it and Form al compound bodies do consist if both were incorporeal, there would then arise from incorporeals a corporeal compound which is absurd. Moreover seeing a body of the predicament of quantity doth alwaies presuppose a body of the predicament of substance; nor can a body of the predicament of quantity exist without a body of the predicament of substance, nor this without that: and that a body of the Predicament of substance, as shal be said, doth immediately inhere in the first matter, and altogether depend thereupon: it must therefore needs be a body pertaining to the predicament of substance. And the first matter hath this its essence of it self, and as *Scaliger saies in his 5. Exercitation*, the matter by that essence which is proper to it self, is that which it is; and in his *17. Exercitation*. The matter hath its *quiddity* or *Somwhatness*, whereby it is somwhat, and differs from other things.

The first matter hath no existency of it self.

And although the matter hath an essence and entity proper to it self, whereby it is somwhat different from the form: yet hath it of and by it self no existency, which

is proper only to a compound, which hath it from the forme: which seeing the matter hath not (which its indetermination that I may so speak witneses) it cannot be said of it self to have actual existence, which is an effect of the forme, but only by the forme, which determines it, perfects it, and makes it to be this or that. The matter therefore is altogether a meer possibility, that is to say, a certain imperfect indeterminate substance, and a rudiment of all sorts of natural things, and which receives al its perfection and all its qualities from the form.

Yet this is thus to be understood, not that the matter is only a possibility to its own being, which it hath of it self by its own Essence; but to this or that sort of Being, as *Scaliger* saies in his 17. Exercitation. Nor is it said to be *Apoios* because it hath no quality, but because every forme and quality which is therein, is without and besides its Essence. For, as *Scaliger* saies, in his 61 *Exercitation.* The first matter, is one *Individuum* or particular being, like a lump of wax, one part whereof bears the form of a Candle, another the forme of an Image; another of a Ball, another of a Die: and the said mass may have as wel this form as that, and challenges none as properly belonging to it self, yet must it of necessity have alwaies some forme or other. Nor was the matter created by God as a certain distinct sort of a natural thing, but it is rather concreate or created together with natural things, and as was said it is as it were a rudiment, Beginning and part of al natural things, nor did it ever exist without any form but only with and under the same.

The first matter is unlimited.

Quantity doth properly follow the Nature of Matter, and is as old as it, nor can be separated therefrom, in deed or in thought. But it is only unterminated quantity I speak of, For terminated quantity doth neither follow the forme alone nor the matter alone, but both of them. For quantity of it self flows from Matter (for, by means thereof al things are termed so great or so great; and it also is the subject of all mutations. Now every thing which is changed, is divisible. *Phys.* 6. Chap. 3. 36.) But not from the forme; for it of it self hath no muchity, is not divisible, only it is extended, and is said to be so great or so great according to the extension and quantity of the Matter. But certaine bounds both external as the Figure, and internal as certaine sorts of Quantity, do proceed from the Forme. For as it streightens the Nature of the matter, and limits it to some peculiar and determinate sort of natural thing: so it limits the Quantity thereof, and imprints thereon, this or that sort and Figure of Quantity. And when we say the Matter, is unbounded, let not any one so understand us, as that the matter either is or hath ever been without certain limits. Nor is it said in respect of the forme to be introduced, in which respect the seed of an Oxe, if you regard the bounds it shal receive from the form of an Oxe may be called a certain unlimited thing; but in respect of all limits, which either it hath or may have from any form whatsoever. For as the matter considered in it self, is altogether without form; yet receives all forms, nor is ever without form: even so Quantity and Dimension of matter which follows the essence thereof, hath of and by its self no certain and determinate bound and Figure; yet is it fit to receive all, nor is it ever found without some Figure and determinate dimension. And thus unbounded and potential dimensions, are in a substance corporeal, unlimited and potential, such as is the Matter: but actual and determined, in a determined and perfect Body.

There is a two fold potentiality of the matter.

Out of the same Nature of the Matter, flowes *Possibility*, or *Potentiality*, which is an apitude or fitness to receive all Forms, and it is *two fold*, *Universal* and *Particular*.

2. *Universal.*

Universal is the Aptitude and propensity of the matter to receive all forms without distinction, and equally respects the two opposite principles, form and Privation, that is to say all forms alike. For matter, to speak properly, hath no appetite to Privation, as Privation, but as another form, and privation is not desired but another form annexed thereto. And this is termed *the first and indeterminate Potentiality*, and the Appetite of the matter, which is nothing else, but the inclination of the said matter to receive any forme. For it is not rightly said, that the matter while it is furnished with this form, does covet another; nor do the changes which happen by reason of the matter, but by reason of contrary forms, nor is there in the matter any appetite of change, but only of perfection. And every part is perfected under every form, and all the matter by all the forms; As *Scaliger* hath it in his 61. *Exercitation.*

Now

Now this universal Possibility, or Potentiality is not the very essence of the first matter taken in the first sense; but only a certaine accident and Natural Propriety, following the Essence thereof. Now no accident is essential to a substance. And though the matter be sometimes termed a Possibility: yet by this word is not understood a Quality, but its substance, which is imperfect, and as it were incompleat, having only a weak kind of Being: or it may be termed a potentiality, meaning a substance in *Posse*, and after this manner of speaking, Potentiality or Possibility is used in stead of a difference, to declare its obscure Essence, and which cannot be easily understood. And although also the matter in its first Notion is termed *Apoios* without Quality: yet may we allow some quality therein; but it must be such as makes no Restriction or Determination of the matter, and does not restrain it to a certain and specifick Nature, such as is an universal Potentiality. For seeing the matter is therefore said to be free from all Qualities and Forms, that it may receive all: and this universal *Potentia* or Aptitude, does not only not hinder but further the Reception of all Forms and Qualities; it is not to be taken from the matter. And this aptitude is as old as the matter and inseparable therefrom. For seeing the matter by reason of its universal potentiality, hath an aptitude to receive al forms; and every day by Reason of contrary Agents, some forms do perish: therefore this Appetite thereof can never be satisfied, and one form going away, it desires to be perfected by another. But this self same universal power or potentiality, is as it were of the Essence of matter, according to the second acceptation. For in as much as the matter is a passive principle; this Potentiality, is as it were its form and constitutes the same. For therefore matter is termed a material principle, because it hath an aptitude to suffer, But a *Particular Potentiality*, is that whereby the matter respects one determinate form: and this does not follow the Essence of the Matter, but is communicated thereto by the Agent, or the form and Qualities, which fit and determine the same, to receive this or that form. So the first matter, being furnished with the form of a Dog's Seed, hath no other Particular Aptitude save that of receiving the form of a Dog. This Aptitude is accidental to the matter, whether taken in the first or second sense, and separable therefrom. For when the *Act* comes, it perishes; and therefore neither does constitute its Essence, nor yet follow the same as an essential Accident. For the Matter, both as it is a being, and as it is a principle of things, subsists without it. For before it received for examples sake, this Particular Form of a Lyon, the Matter was actually in being, and when it shall have laid it down, it will remain in actual being. Seeing therefore this Determinate and Particular power or Potentiality, is not one alone, but many according to the variety of Forms, and the matter may exist without any one of them: none of them constitutes its Essence, or properly follows the same: moreover nothing Definite or Determinate does constitute its Essence; or can depend thereon. Possibility indeed or potentiality as such does immediately depend upon the Essence of the Matter, and is an essential accident or adjunct thereof: but in as much as it is definite, and respects this peculiar Form, it is not from the Matter, but from the the Agent and present Form, which is a privation of the Form to be introduced. And therefore it is not as old as the matter, but is separate therefrom (as hath been said) when the Act comes, it is separated. This Particular power or possibility, is only opposed to the Act, as Privation is to the Habit: the universal is not opposed thereunto. For *that* does not respect any peculiar Form: but an infinite multitude of them.

2. Particular

And this is the Doctrine of the Peripateticks concerning the first matter: yet not different from the Tenets of the Platonists, as we may see in *Alcinous* in his Book *de Doctrina Platonis* Chap. 8. in these words. *He* (viz. Plato) *cals the Matter, the Receptacle, Nurse, Mother, Place, and Subject of all things; and he saies that it is felt without sense, and comprehended by a bastard kind of reasoning. He will have it to be the property of matter, to receive al Generations, and like a Nurse to cherish them also to receive all formes, seeing it self of its own nature is void of all Quality, Form, and Figure. Also he saies that it is sprinkled and figured with shapes, like a Picture, having of it self no Figure or Quality. Nor were it a subject fitly prepared for sundry impressions of forms, unless it were quite void of all those Qualities, which it is to receive. For we see those that would make sweet ointments of Oyl do seek for Oyl infected with no smell at all: and those who would print forms upon Wax, or Clay, do first work & smooth & polish the*

matter,

matter, til the old figures are quite blotted out. For it is fit that the universal matter, if it be to receive all forms, should not have in it self the nature of any of them, but that without all Quality and Figure, it must be the subject of several sorts of things. And being such as is said, it is neither a Body, nor yet incorporeal, but potentially a Body, even as Braß is potentially a Statue, because receiving the figure it may become a Statue.

Privation and Negation how they differ.

The *other* Principle of Generation is *Privation.* That we may understand what that is, we must see how it differs from negation. For Negation is of larger extent than Privation, and is attributed to matter taken in the first sense, and denotes an universal Absence of all forms and Qualities in the matter. But such is not privation: (for one Privation is not opposed to all forms, but to every one a proper) but it agrees to matter taken in the second sense, and alwaies presupposes other Qualities, and is necessarily conjoyned with some form, which goes next before the Form to be introduced. For the Privation of the form of Wheat, is not an universal negation of all formes in the first Matter, nor yet every other absence thereof, as for example sake, that which is in Iron: for Wheat is not generated of Iron: but that which acompanies some definite and determinate form, *viz.* that of the grain of Wheat. Hence *Themistius* upon *Aristotles Posteriora*, writes thus; Privation is a Negation in a determined subject, and *Alexander de Ales* upon the Metaphisicks; Privation essentially requires the Negation of a form with an aptitude to receive the same. And the very same *Scaliger* affirms in his 18. *Exercitation.* Privation (saies he) seems to have the Nature of a certain Being. For it is the same after a sort with that Habit, which is contrary to the Habit, whereof it is a privation. And therefore as *Zabarella* saies; Privation is in its own nature, the absence of a form, and it is nothing, and is opposed to a form only Privatively, but inasmuch as another form alwaies accompanies the same, in which respect the privation of that thing is properly said to be some positive thing having contrariety thereunto. We gather therefore from the Premises; that *Privation* is the Absence of a form in that Matter which is immediately disposed to receive the same. Now Prvation is not of the Essence of Matter, but an accident thereof being taken in the seond sense, being necessary, not simply, but in respect of Generation. For it concurs with other Principles to the Generation of a thing; and it is in Generation as it were the term from which the motion is made. For that which is generated, was not before; yet it was possible, and in generation not being goes before Being: and therefore it is called a third Principle essentially distinct from matter: and matter concurs *one* way to Generation: Privation *another.*

what Privation is?

It is not of the Essence of Matter.

The Form

The *third* Principle of natural things we make to be the *Form*, which because it is the most excellent of all, it requires more diligent consideration. That there is somwhat in things besides the Matter, called Form, all in a manner do grant: but what that is, whether a Substance or an Accident, all are not agreed. For there were both Phylosophers of old, and some there are at this day, who conceive there is no substantial form in the matter. Yet verily, that is the truer opinion which saies that there is in every natural thing, besides the matter, some substantial form, which is naturally before all the accidents or adjuncts, both common and proper. For the Parts of a Substance, are themselves also substances. And if things did consist only of matter, the Essence and operation of all things, would be one and the same, and there would be no true distinction betwixt them. For from accidents a true diversity and distinction of Essence and Operations cannot be drawn. For the Act and essential perfection of a thing, whence its difference is taken, does belong to the same kind, wherein the thing is placed: or as *Toletus* saies, No imperfect thing in any kind is pefected in that kind, save by somwhat of that kind. Since therfore Matter is an imperfect Substance, and is perfected in the compound; it must be perfected by another Substance, *viz.* The Form. Moreover, the diversity of Accidents and Operations, whence proceeds it? Why is the fire not cold, but hot? not by reason of the matter: for that operates nothing, makes no distinction, but is void of al Quality. Therefore we must presuppose somthing more noble than an accident. Finally, if the Form were an Accident, there would be no Generation of any thing, but only an alteration.

The form is of its self an incorporeal Substance

The Form therefore is a Substance of it self; and indeed incorporeal; of it self void of all Quantity, Demension and Division. But it participates of Quantity by Accident,

Accident, *viz.* inasmuch as it is inherent in the Matter, according to the extension and division whereof, it is extended and becomes divisible. For as the matter is not, so neither is the form perfect of it self, nor constitutes any sort of natural things; but it concurs together with the matter, to make up the compound. And therefore neither the matter nor the form, hath of it self all things requisite to make the compound; but each wants the others help, and they mutually assist one another. The form wants the matter to sustain it; and therefore some call the Matter *Principium Subjectivum formæ*, the Principle of the form, or that Principle wherein the form resides; upon which the form depends in its making and conservation. But the matter is perfected by the form and from it receives its actual being and perfection, and therefore some call the form, the formal Principle of the matter; not because it gives it its Essence, but because it perfects the same. The whol nature therfore of the Form consists herein, that by a real conjunction with the matter, it may give it that perfection which is proper thereunto, and so with it constitute the compound. And therefore it is by *Aristotle* in the second of his Physicks Chap. 3. Text 8. defined to be, *That which makes a thing to be what it is*, and in his 6. Book of Metaphysicks Chap. 8. I cal the form that which makes a thing to be what it is, and the first Essence of a thing; and in the 6. of his Metaphysicks Chap. 11. *For the form is the inward substance of a thing, from which also the whol matter is called a Substance.* For the form is a simple substantial Act, with the matter making one entire compound. For this is the end of Generation; by it the matter is perfected; it is coveted by the matter; herein the matter finds it self contented; from it al accidents and actions flow.

The Original of Forms.

But, *Concerning the original of Formes*, there is a very great controversie amongst Phylosophers, which hath exercised the Brains of the most able amongst them; nor seems it as yet sufficiently determined whence the forms have their Original. For though *Aristotle* and his Expositors do say, That neither the matter is generated, nor the form, but the compound yet their Intent is not, that both the matter and the form are generated at one and the same time (for the matter is not generated, nor can be) or that some third thing different from these is produced; but this they would signifie: that the form is not produced by it self apart from the matter and without it, and afterward joyned thereto; but that it is produced in the matter and joyned therewith. For the compound is nothing but the matter and form joyned. Therefore we must grant that in some sort the form is made, inasmuch as it is the Butt and End of Generation.

Whence the forms proceed?

This being granted we must see *Whence the forms have their original.* If you shal ask a Peripatetick or follower of *Aristotle* (setting aside at this time the Opinions of *Anaxagoras Plato*, and *Avicenna*) He wil tel you they are drawn out of the Aptitude or Potentiallity of the matter. I hear indeed (to use the words of *Scaliger* in his 61. exercitation) the sound of words; but I desire somthing to satisfie my mind: but I hear nothing. For though this expression be worn thredbare by many yet few do sufficiently explain what we are to understand thereby. But this seems to be the opinion of those who do think most rightly: for forms (excepting the humane Soul) to be drawn out of the power of the matter, is nothing else, but for them to be so made in a subject having a natural aptitude unto them, and existing before them both in time and nature, as that both in respect of their conservation and operation, they do so depend thereupon, that out of it they neither can be made, nor preserved, nor operate. For the form which is educed, is not at first produced apart from the matter, and out of it, and afterwards externally adjoyned to the matter, but it is produced in the matter. And so *two* things are required to the eduction of forms: *First*, That the Subject have a natural aptitude to the form: *Secondly*, That the form which is drawn forth, depend upon the matter both in their making and conservation; that is to say, that without the help of the subject, and out of it, it can neither be produced, nor preserved, nor operate. And consequently al natural forms, except the humane, do so depend upon the matter, that out of it, and without the assistance thereof, they cannot be.

What it is for forms to be drawn out of the power of the matter.

Whether the Form be made of nothing in the matter

But if any man, not content with what hath been said, shal further urge, and say, that he acknowledges what hath been said to be true, *viz.* that for a form to be drawn out of the aptitude of the matter, is nothing else, but for a form to be made in the matter, and not out of the same: but shal yet enquire; whether in the matter,

Form is made absolutely of nothing. Which *Picolominæus* seems to conceive in his 1. *Book of Creation Chap.* 7. So that the Agent affords nothing of its own Essence thereunto, but action only; or so as that the Agent does not communicate the Forme it self, but brings the Aptitude of the matter to such a Form into Act, causing the Potentiality of the matter to break out into a formal Act. But whether a new Form comes out of the Essence of the old Form, is an hard question to answer.

The Original of the forms from whence it is?

For seeing naturally, nothing is made of nothing, and a Form is now in the matter which was not there before, the Question wil be, whence is its Original? How the Interpreters of *Aristotle* do torment themselves, about this point is every where to be seen, and among the rest out of *Toletus* in his Comments upon the 1. of *Physicks* Chap. 9. quest. 19. and upon the first *de Generat.* and *Corrup.* Chap. 3. Quest. 2. where he reckons sundry opinions of the Peripetaticks in this point. For in the first place, some mentioned by *Du-Rand* in his 2. *B.* upon the Sentences D. 18. did hold, that there did precede in the matter certain Entities, out of which afterward the Forms were made, *viz.* several forms out of the several Entities, and these Entities or Beings, they called Possibilities of Forms. Secondly, Others think, that the parts of the forms precede in the matter, but very remiss, and that afterward they are in Generation vigorated and that so every form is precedent in the matter, in a weak manner of Being. Thirdly, *Albertus Magnus* held, that al forms did essentially precede in the matter, so the that Matter is a kind of habit prepossessing al forms essentially.

But *Toletus* acknowledges the Absurdity of these opinions, and therefore he determines, that there was nothing of the form in the matter, which did precede the introduction thereof; and this he proves by firm reasons which you may see in the forecited place.

Others that they may avoid these absurdities, do attribute this power to the Efficient, and some with *Plato* make the Ideas to be the efficient Causes of the Forms: and others since have brought in the Soul of the world to that intent: *Avicenna* hath invented a tenth Intelligence, whom in his own language he cal's *Cholchodea*, & gives him this office of making forms. *Fernelius* with some others makes the Heaven to be the efficient cause of forms. But if that were so, Generation would not be univocal, and the form not having been in the matter, must be held to be created. Howbeit that does not please other peripetaticks. Wherefore *Piccolimineus* in his 2. *B.* of the Principles of Natural things, although he grant, that the form is in part made out of nothing, because nothing of it was before in the matter; yet he denies that it is created, because it presuppose's a Subject, out of which it is educed. But *Tolet.* in his 1. *de Gener. & Cor.* sees that this answer, which was also *Marsilius Ficinus* his answer, wil not hold, and therefore he writes: This Doctrine does not please me. For verily if the production be of the form it self, seeing no part thereof was precedent in the matter, it must be called a Creation. And the truth is, whether the form be produced in the matter or out of it. if there were nothing thereof precedent, it must be a Creation; which himself acknowledges ought not to be attributed to natural agents.

He therefore, to free himself from this difficulty, determines: that what is first generated and corrupted is the compound; and that the form is not produced by it self, but comproduced and made together with the production of the compound, and that the Action is first terminated upon the compound it self, and consequently and as it were by accident upon the form.

But in very deed, whether the Form be made in the first or second place, or consequently, whether alone or with the compound, the Question remains just as it was; *viz.* Whence the form, which now is in the matter and before was not, hath its Essence; whether it did præexist in the matter, or was made by conversion of matter into form, or of nothing. For it does not follow that if the finger be made with the hand it is therfore made of nothing. Yea the compound should rather be said to be made consequently and in the second place, than the form. For as whiles Wood, Bricks, Morter and other things are made and compounded, an House is consequenly made: even so a natural compound, which is nothing else but matter and form, is made, when the Matter and Form is made. And seeing the matter is not made, what else shal we say is made except the Form. And therefore when he observed, that he neither satisfied himself nor others; and saw that no part of the form

did

did preexist in the matter, nor could a power of creating be attributed to Natural Agents; at length in his 1. *de Gener. and Cor. Chap.* 3. *Quest.* 2. He concludes: I confess this is an admirable power and Virtue, which partakes somwhat of a creating power: but it is no such creating power: seeing it hath alwaies subjects to work upon. Also the Virtue of the matter is wonderful, out of the Aptitude whereof things are produced, which actually are not there. But in very truth, that virtue is not wonderful, because there is none such, but their wilfulness is wonderful, who will have that to be drawn out of the matter, which is impossible, as not being in the power either of the matter or of the Agent. For many men had rather rest upon certain principles, which cannot satisfie minds covetous of the truth, then make profession of that which is the manifest and solid truth. Which they perhaps therefore do that they may be thought good Phylosophers: whereas, doubtless, *Aristotle* if he had known the first and true Original of Forms, and the Creation of the world, as we do, he would have left us, a Natural Phylosophy better and more compleat then he hath done.

Let us therefore to whom these things are made known out of the holy Scriptures, omitting those opinions, which endeavour to bring the Forms out of the matter, or from Heaven, or from elsewhere, determine that the Forms themselves, as also the matter, were at the beginning of the world created with the things themselves, that of them all Natural things might consist: And that the first matter cannot indeed be generated but that by means of the Forms, all changes of generation do happen, and that the Forms are the second principle of Natural things, by which they are that which they are, and do that which they are commanded to do; that according to the Forms al Naturul things do not only act, according to their Nature, that is to say, as the Creator hath commanded them to act, but thereby they are governed, preserved and propagated. For God commanded, that natural things should not only exist by their Forms, but propagate themselves thereby, and as he commanded it, so he gave every of them a power to do so as he commanded, and forthwith to encrease and multiply which command of God (that no man may bring the Forms out of Heaven) appears to have been given out before the Heaven was created. *Genesis*, 1. verse, 11 and 12. *And God said let the Earth bring forth Grass, the Herb yeilding Seed, and the Fruit tree yeilding Fruit after his kind whose Seed is in it self upon the Earth: and it was so. For the Earth brought forth Graß, and the Herb yeilding Seed after his kind and the Tree yeilding Fruit, whose Seed was in it self, after his kind: and God saw that it was good.* All Natural things do therefore obey the command of the Creator, and al Forms, as in the first creation by a power put into them, do beget by promotion and propagation of themselves; they remaining nevertheless in the mean while entire; which also we see in Plants and Animals, which generate by Seed. For they when they afford Seed do afford somwhat of their matter and somwhat of their form. For the Seed of a plant while it is in the plant, is animated with the Soul of the plant. But when it is separated therefrom, that portion of the Form, which is Inherent in the Seed, and together with the matter, of the Seed is separate from the Plant, grows into a plant like to that from whence it came. And the same holds in Animals. And therefore the Form is Potentially in the Seed; because as *Scaligar* saies *in his 6. Exercitation, Sect.* 5. The Seed is able to give the Form: it is therefore drawn out of a remote possibility, which is the first act, to a near possibility, which is the Second Act. So that the Form is in the same matter, after the same manner as, to need no helps, but to enjoy its End and to which the whol compound is ordained: which is then brought to pass, when the Form does constitute its own matter, and Alter, Labor and dispose it as if it were its House. And therefore when a living Creature is made of the Seed, the Form is not then first induced thereinto, but exists therein already being communicated by the Ingenderer, and it does only by assistance of the wombs Heat display it self; which is rather a certain arising or springing out, then a drawing out. To be short: This is common to all Forms (though to some in a more noble, others in a more inferior degree) that they can multiply themselves, are incorporeal, have of themselves no dimension or Quantity, nor do of their own Nature take up, but do fil. And if we suppose the Body of any Animal or Plant to grow never so big, yet the same Form without any Addition will fil it all: and though it be never so much lessened, the Form is no waies lesse-

ned or impaired. But let us conclude this discourse with the words of *Scaliger* in his 307 *Exercitation, Sect.* 29. *The matter is a possibility, apt to be perfected: the Form is an Act, fit to perfect. And thus we see the shallowness of mans understanding, who is so bold as to say he knows the Forms of substances. But this exquisite knowledg is hid from our Eyes:* viz *How of two things, one is made. How the Form is totally in the whol and in every part of the compound. So divine a thing is the Form, that being a substance, it fils another substance so ful of it self, that of both one is made. Wherefore to search further, is the part of an overcurious and busie mind. For it is a part of Mans Wisdom, to be willingly ignorant of some things.* Yet we must not reject as falf, such things as are hard to be known. For (as *Plato* saies in his Dialogue called *Theætetus*) *they are profane who think there is nothing, but what they can feel and handle.*

Chap. 4. *Of Nature and the Causes.*

Divers significations of the Term Nature.

THere are sundry Significations of the word Nature, which you may see in *Aristotle, in the* 5. *of his Metaphysicks, Chap.* 4. *And in* Pererius, *in the* 7. *of his Physick, Chap.* 1. *In* Piccolomineus, *in the* 2. *of his Physicks,* p. 249. *In* Fonseca, *in the* 5. *of his Metaphysicks, Chap.* 4. I shal cite only some which are most suitable to our present matter in hand. And in the first place, some cal God himself by the name of Nature. Again, others take Nature for the second Causes; in which sense *Scaliger, in his* 188. *Exercit. and* 359. *Sect.* 11. seems to define it to be the ordinary power of God. Thirdly, Nature signifies the whol Universe of things. Fourthly, Nature is taken for the Essence of every thing; in which sense we say that things separate from matter, as God and Angels have a Nature, that is to say an Essence. Fiftly, Natural is opposed to voluntary, so that a thing which acts without deliberation is called Natural; and that which acts with Deliberation, Voluntary. And yet more strictly, Natural is opposed to Animate, and Nature is taken for a Faculty opposite to the knowing Faculty. For seeing the knowing Faculty respects both parts of the opposition, and is apt to do as wel this as that contrary: Nature, contrariwise, is said to be that which respects but one contrary, and is only determined thereunto. Finally, in a certain middle way, betwixt these last significations, Nature is said to be the internal principle of motion; and every thing is said to be Natural which is mutable and variable. And in this place we treat of it, in this last signification: and that we may the better find out what it is, let us see how Natural things differ from things Artificial.

Things Natural and Artificial how they differ

All things in the whol Universe are of two kinds: some are from Nature, as the Elements, Living-Creatures and their Parts, Plants, *&c.* And some again are from other Causes, as Art, Counsel, Fortune, Chance. And although things Natural differ from Artificial many waies, as may be seen in *Pererius, Lib.* 7. *Phys. Chap.* 2. Yet this difference shal serve our turn: that Natural things have an inward Principle of their motion and rest: But Artificial things, as such, and of themselves, have no such principle. For whereas a Statue or Image tends downwards, it does it not as a Statue: But as consisting of Stone or Wood. Since therefore Natural things are hereby differenced from Artificial, Nature is not unfitly defined to be *the Principle of Motion and rest in that thing wherein it is primarily, of it self, and not by accident.*

The definition of Nature.

But before we pass to other things, that this definition may be rightly understood, some things are to be hinted. And in the first place you must observe, how Nature is said to be the principle of Motion and Rest. For it is not so to be understood, as if Nature did effect both these together: but one after another. Nor as if there were the cause of both in every Natural thing. For every nature is not the principle of Motion and Rest. But it is thus to be understood, that all things which naturally move and rest, have this motion and rest from nature. For there are some things that alwaies rest; some which are alwaies moved; some which both rest and are moved, and yet nature is the Cause of al these. Moreover, this is not to be forgot; that every nature is not the principle of every motion, but this of that, and another of another; nor is every natural body moved with all motions.

And

And by Rest we do not understand every Cessation from motion, and every privation thereof: but to rest, is to remain in its Natural place. So Earth, when it comes to its place, it hath a Principle whereby it Naturally rests therein, and removes not therefrom unless by violence forced. And whereas in the Definition it is said, that Nature is a principle of motion and rest, in that wherein it is; thereby, Nature is separated from Art and from an external Agent, which are the Causes of a Transient operation only. Yet, I deny not but that Nature is the cause of a Transient Action. For Fire heates also other things. Howbeit, *Aristotle* would define Nature, only by an immanent Action, because thereby it is manifestly distinguished from Art. And if the definition of *Aristotle* be so explained, that Nature is the internal principle, from which every thing hath a power of acting and suffering, and ceasing from both; all seeming difficulties wil be cleared up.

A two-fold principal of motion active and passive.

The passive what?

And because the principle of Motion is twofold, one Active, by which the motion is effected, another passive, Wherein? hereupon arises a double controversie amongst Authors. First what we are to understand by a passive Principle: Secondly, whether Nature be both these Principles or only one of them. As to the First, a passive Principle may be understood two manner of waies, First for the passive Aptitude of things opposite which is free, and not more apt to receive of it self, one motion more then another, but is equally propense to both: Secondly, For a power already restrained, and limited, to one only of the Opposites, and Determined to one Motion, which is said to be the Natural motion of the thing. I am of the latter opinion: for from the former, this absurdity seems to follow that all violent and Artificial motions, may be called Natural; seeing the first matter is of it self alike disposed to receive all Motions.

Nature is a principle as wel active as passive.

As to the other Controversie: although some have said that Nature is only an active principle, others that it is only a passive; Yet I conceive, both may well be affirmed of Nature. For to things having Nature in them, it is no less Natural to move themselves, then to be moved by themselves.

To what things the term Nature may be applied.

And from what hath been said it is now apparent what is Nature in things, *viz.* The principle of motion and rest, both active and passive. It remaines that we now declare, what that is, and to what things the name of Nature is due *Aristotle* gives the name of Nature both to the matter and the Form: and that not amiss, provided he be rightly understood. For the Form alone primarily and of it self deserves to be called Nature: and it is a Principle of motion as well active as passive. But because the matter is indifferent and doubtful, disposed to receive contrary motions, respecting no determinate motion, but al indifferently: it cannot primarily and properly be called nature. For so, as all natural things have one matter, so should there be of all but one Nature: whereas nevertheless every thing hath its own peculiar Nature. Yea, if so be the matter as well as the Form were Nature, every thing should have two Natures. Nor is it absurd to cal the Form a passive principle. For seeing, as hath been said, a passive principle, is not so called, in respect of every indeterminate motion; but only of that determinat and certain motion, which is peculiar and natural to every thing: by very good right, the Form also is called a passive principle; since from it proceeds al determination and restraint of matter to the reception of certaine determinate Motions. Now the Form is termed a passive principle, in as much as it is in the matter (for in respect of the matter every thing is said to suffer) and determinates the Nature thereof: and in as much as it is the Form, it is also termed an active principle. The matter, notwithstanding as hath been said is also called nature: not because it is nature of it self; but only potentially: or because it hath an aptitude to receive the Form, which of it self is Nature. Actually therefore the Form is nature; potentially the matter.

The Form is cheifly Nature.

The whol Sum therefore of this discourse is this: One thing hath one nature, which properly and primarily is called the Form. For this of its self is the active principle in things, and in as much as it is the Form: and also the passive, in as much as it determines the doubtful nature of the matter. And therefore to be a passive principle, is in divers respects attributed both to the matter and the Form. For the matter is the Passive principle, not as it is barely the matter but in as much as it is furnished with some Form, whereby it is determined to receive some particular motion. The Form is a passive principle, not as it is the Form, but as it determines

the

the doubtful nature of the Matter. And thus neither of them without the others assistance, can be called a passive principle.

whether every Form informing be Nature

From what hath been said, it may easily be collected, what may be determined in reference to that controversie, Whether every Form in forming, is to be counted Nature, or not. The Definition, truly, of Nature doth evince: that every form informing, inasmuch as it is inherent in the matter, and informs the same, may rightly be called Nature.

Things natural & according to nature, how they differ.

It is now manifest what and what kind of thing Nature is. One thing must yet be added: What that thing is which hath Nature, and what that is which is according to Nature. Natural things are Substances which have nature in them, *viz.* A principle of motion and of rest. Such are only natural Bodies. For that thing is not called natural, which produces any thing that is natural; for so God himself should be reckoned amongst natural things. Nor is that said to be natural, which is produced by naturral motion; for so the first Man and this whol world should not be natural. But that thing is properly natural, which hath an implanted Principle of its motion and rest. And such a definition of a natural Body, does comprehend all bodies both Celestial and sublunary. But according to nature, is of larger extent, than having Nature, or Natural; for according to nature, are not only the Substances, but also their properties, and their affections or adjuncts which follow their Nature. *And so much of Nature may suffice to be said.*

But inasmuch as nature is chiefly considered in this place, as it is referred to motion, or, as they say, it hath a peculiar Causality over the motion and rest of that thing wherein it is: the *Causes* are now to be explained, *viz.* inasmuch as they have respect to motion; and we are to consider what kinds of Causes have place in things natural. They define a *Cause* to be that by the virtue or efficacy whereof any thing is made: or by which any thing is of it self produced. Now they are four: The Matter, of which a thing is made and subsists: The Form, by which a thing is that which it is, and nothing else: The Efficient, whence proceeds the Beginning of Mutation or Rest: The End, for the sake whereof a thing is. Nor is there need to invent more Causes; seeing by these we can sufficiently Answer any Question, why a thing is, and whereby the cause thereof is demanded. Yet there are more Modes or manners of Causes. For a Cause is neer or remote: of it self or by accident; in act or in aptitude, simple or conjunct, of which see *Aristotle* in his 3. of *Physicks Chap:* 3.

what a Cause is, and how many causes there are?

The Manners of Causes.

Fortune & Chance, how they differ?

To Causes by Accident, Fortune and Chance are referred. For seeing some things are made alwaies or for the most part, others seldom; again some are made for some ends sake, others for none: and those which are made for an end, are made either by Election or without Election: Fortune and Chance are said to be the Causes of such things as happen seldom & without an end propounded. And herein Fortune and Chance agree, that they are both the Cause of such things, which are not alwaies or for the most part, but seldom effected, and which are undertaken for some Ends sake. Yet herein they differ, that Fortune is of things done with Election, and Chaunce of things done without Election.

what Fortune is, and what Chance?

Fortune therefore is the Cause by accident of these things, which among things done by Election and for some end, do not alwaies nor frequently but seldom happen. And in such a sense we may grant, that there is both Fortune and Chaunce in things. But in respect of the most great and good God, nothing happens by chaunce or by fortune.

whether it belong to a natural Physosopher to consider the Causes?

But it is the part of a natural Physosopher to consider all the four kinds of Causes, and by all four answer may be made to that question why or how a thing comes to be, and that physically. For it is the part of a Physitian or natural physosopher, to consider the Parts and Principles of a body natural. And to him it belongs, to explain the mutation and generation of things and their causes; and to see for what things sake, the Efficient acts, or to enquire into the end: moreover to weigh and consider what is made, or what form is introduced afterwards, to know what that is which suffers and receives the form, *viz.* the matter, finally to search out the efficient which introduces the form.

Howbeit we are to know, that the three Causes, Efficient, Form, and End, are in natural things many times united together, and grow into one Cause: so that the form and end, though they differ in definition, yet in number

and

and subject they are one Cause: but the formal and efficient cannot be one in number, yet one in kind. For the same form of an animal, is at the same time both the form and end: the form in respect of the thing Generated, inasmuch as it is an act perfecting the matter, and therewith making up the compound: but an end in respect of the Generation. For it is the Butt to which nature tends, and wherein she rests contented after it is attained. Moreover the same form is also the Efficient, inasmuch as the thing generated, is of the same species or sort with the Generator.

This thing also is to be noted, after what manner every cause, does concur to the Production of the Effect. The End concurs to the production of the Effect no otherwise than as it moves the Efficient to produce the same, and after the thing is effected, all the causality thereof ceases. The Efficient concurs sometimes only to the production of the Effect, and sometimes also to the conservation or preservation thereof; which latter efficiency does chiefly belong to the universal Causes, which *Scaliger* does excellently shew, in his 28. *Exercitation. It is not* (saith he) *necessary, that the particular efficient Causes should be perpetuated together with their Effects: but then only to stick to them when they work. For it is enough that they give them their form, whereby not only they are, but are preserved: since out of their matter the qualities being driven by their contrary, the form also is forced away. Only the first Efficient, because he is Lord of Eternity and the world, accompanies his effects: there is no necessity that other Efficients should do so: no not the Heavens themselves, otherwise than by his favor and Indulgence.* So far *Scaliger*

But the Matter and Form are necessary both for the Production, Constitution and Conservation of the thing.

And although there were anciently, some who thought all things were made at random and by hap hazard: yet we avouch that God and Nature do nothing in Vain. Yet we do not here introduce a simple Necessity, but only a conditional, and therefore we do not deny all Contingency in natural things.

Many things might be added touching the Causes; but all that may be said of them, belongs not to our present Purpose, also I endeavor to be as brief as may be. Only one Question we shall here discuss, *viz.* Whether an accident can produce a Substance. There are about this Point Three Opinions. The first is of some late Writers who aver, that an accident by its own proper Virtue can produce a Substance? so that when Fire produces fire, that whol production intrinsecally and effectively proceeds from Heat, nor does the substantial form which is in the fire concur to the effect. The second, is the Opinion of *Scotus*, *Ocham*, and *Du-Rand*, who teach, that Accidents can neither by their own proper Virtue, nor the power of substantial forms, produce a substance: but that a substance is immediately produced by a Substance. The third is the opinion of *Thomas Aquinas*, who avers: That accidents do not produce a substance by their own proper force, but by the power & virtue of the substantial forms, whose virtues and Instruments they are. This last opinion seems to me most probable. For that substances act mediately, any body may hereby learn, inasmuch as the things between which there is action and passion, are many times, we see, in several places: whereas, nevertheless a mutual contract betwixt the Agent and Patient is necessary, and the Agent and Patient ought to be together. And that Accidents cannot of themselves produce a substance, does hence appear; in that whatsoever is in the effect, does præexist in the efficient cause. For nothing gives that which it self hath not, either formally or eminently, as they say.

Whether an accident can produce a Substance?

Chap. 5. *Of that which is continued, and of that which is infinite.*

NOthing is more intimately inherent in a natural Body than Quantity; as being of equal durance with the first Matter, and altogether inseperable therefrom, and by help whereof, all the remaining Accidents do adhere to the Matter. Yea and by a Body in the predicament of Quantity, we come to the knowldg of a substantial Body, which is nothing but a substance that hath three dimensions of Length, Breadth, and Thickness. For these differ one from another, like Substance and Accident. In Subject they are one. For that Body which consists of Quanti

ty, is not without a ſubſtantial Body: but they differ eſſentially, having different eſſences, when no man thinks of them.

What continued Quantity is & how many fold. A Line.

Now continued Quantity is that whereof we cheifly treat in this place; whoſe bounds are one; or whoſe parts are coupled with a common boundary. And there are three ſorts thereof; a Line, a Surface, and a Body, each of which hath its peculiar Office and Peculiar bounds. For a Line is a Longitude without Latitude, the bounds of a Surface. The bounds of a Line is a point: whoſe Nature is to continue touch, terminate. For it begins, continues and ends a Line. The Nature alſo of a Line is to continue, Touch, Terminate, and alſo to divide. For by a Line a Surface is continued, and Terminated, and by the ſame, two Surfaces, do mutually touch one another: Finally by means of a Line, every thing is diviſible according to one dimenſion, *viz.* Longitude. A Surface is a Quantity long and broad; by means whereof Bodies are continued, do mutually touch one another, and are divided. For by means of the Surface, a thing may be divided according to a two-fold dimenſion, *viz.* Longitude and Latitude. Finally, a Body is a Quantity, Long, broad and deep. And its Office is not to continue, terminate or touch; but to fil and poſſeſs, and to be apt to be divided according to its threefold dimenſions, Length, Breadth and Depth.

A Surface

A Body.

Things poſſeſs a place only in regard of their being bodily.

Thus therefore, in reſpect of all dimenſions things are ſaid to have Quantity and to be diviſible: but in reſpect of a body only they poſſeſs and fil. For that two bodies cannot be together in one place, is not becauſe they are ſubſtances: For divers incorporeal ſubſtances, may be together in one and the ſame place: but becauſe they have matter furniſhed with a threefold dimenſion, the Penetration whereof is impoſſible.

To take up and fill do differ.

Here I muſt take leave to digreſs a little, and propound ſome things not much from our purpoſe, To poſſeſs or Occupy, and to fil, is for a body to be ſo in a place, as that another cannot be in the ſame place with it: and it is proper to ſuch things as have matter of a threefold dimenſion. For ſuch things do ſo take up the whol place, that another Body at the ſame time cannot be therein. But thoſe things are ſaid to fil, which may either in any of them together, or with other bodies, be in a certain place, ſo that the Preſence of one ſhall not hinder the preſence of another. And therefore two bodies can never be together, nor can two hold the ſame place: and as the common experſſion is, Penetration of Dimenſions is impoſſible. For Naturally it cannot be, that into that place which any of us fils, another Man, or any other Body, ſhould be admitted, til we leave the ſame. But it is otherwiſe in things free from dimenſion and Matter, and in all Forms, ſubſtantial and accidental, which is manifeſtly apparent in the light of the Stars, for the lights of infinite Stars, are every where ſhed and ſpred about under the Concave of the Moon, nor do the Elements at all hinder them, by whom this ſpace is before poſſeſſed, nor does the preſence of the one hinder the preſence of the other, nor though they are all of them in all places, are they confounded or jumbled together. The ſame we ſee in other things which give light. For if you place Looking-Glaſſes upon the walls of a chamber round about, and ſet candles in the middeſt of the ſaid Chamber. They will all ſend their image and light into all parts of the Chamber, already ful of Aire, nor will the preſence of one hinder the other, nor wil they be mixed or jumbled together: but they will all appear diſtinctly, in all the Glaſſes. So in Honey, in all parts thereof there is yellowneſs, and ſweetneſs, and ſmel and moiſture. And the ſame happens in ſubſtantial Forms. For both our Soul and the Soul of all living Creatures, does fil all the Body, which it informs, nor though a Body have before taken up the place, is it hindred from being in all parts of the Body. It is therefore the Property of things which have dimenſions and are corporeal, to poſſeſs and take up: but of things free from dimenſions and matter, to fil: and by how much a thing is more free, from dimenſions, Matter, and bodily bulk, by ſo much the more it fils. Hence we ſee a ſound fils a greater ſpace, then a ſmel, and colors greater then ſound; and the light of fire yet a greater, and the light of the Heavenly bodies, a greater then that. Finally the moſt good and great God being infinitly free from all dimenſions and from al matter, does infinitely fil all things, yea is himſelf an infinite fulneſs, abſent from nothing, included in nothing, nor mixt with any thing; but is totally al the world over, and totally every where without this world. For though he is preſent with all things, yet is not

Why two bodies cannot be in one place?

God is preſent repletively

ſome

some part of his plenitude present with one thing, another with another, but he is wholly present with all things. Finally this world is made in the Atome, indivisible point or Centre of his fulnes. And therefore, al things void of matter, and all forms, of themselves, have neither Quantity, nor can be divided, unless by accident, in as much as they are inherent in a body by whose dimensions they are bounded, and may be many of them together. For dimensions being taken away, the Form of any of us, may be with the Form of another, in the same place, and fil the said place, nor should the presence of one hinder the presence of another. And we see the same Form, which at first fits the Body of an infant, fil the said body without encreasing it self, when the infant is grown to a tall Person.

Forms of themselves are without Quantity and indivisible

But let us return to Quantity: where we are fallen into that most noble question which hath exercised the wits of so many renowned Men: *viz.* Whether a continued Body is made up of indivisible parts, or of parts divisible? And whether that which is continued may be divided infinitely? There were anciently some that held, that a continued Body was compounded of indivisible parts, as *Pythagoras*, *Democritus*, *Leucippus*, and the greatest part of those who flourished in *Aristotles* time, and the Stoicks themselves who in this point followed their Ringleader *Zeno*. But *Aristotle* undertakes their refutation, in the Sixt Book of his Physicks. Also they are opposed in that which is called, *Of Indivisible Lines*, which goes up and down under *Aristotles* Name, which some deny to be *Aristotles* Book, though according to his judgment, and collected from his publick discourses. And in this point the most excellent Phylosophers and Mathematicians do follow *Aristotle*. And though weighty Reasons be alledged on both sides yet shal I side with *Aristotle*, and that for these Reasons following.

Whether that which is continued be made of indivisible or of divisible parts?

In the first place, if that which is continued be compounded of indivisibles, as for examples sake, a Line of Points, one indivisible with another, wil either make a thing continued, or a thing contiguous, or a thing whose parts are ranked one after another. But none of these can be. And therefore that which is continued is not compounded of indivisibles. Indivisibles are not continued. For continued things are those whose outmost bounds are one and the same. But the outmost bound of Indivibles is not: for every extream is distinct from that thing whose extream it is. And therefore indivisibles are not continued. And for the same reason likewise they cannot be contiguous. For those things are contiguous whose extreams are together. The same is also thus proved. What ever touches another thing, touches it either as an whol touches an whol, so that all its parts are together with the parts of the other, or as a part touches a whol, or as a part touches a part. After these latter manners, things indivisible cannot touch one another: for that which is indivisibe hath not parts, nor can it be parted. Nor yet after the former manner. For every thing continued, hath parts without parts, so that one part is seated here, another there. If therefore in the making of a Line, the points should totally touch one another, and in making a surface, the Lines should totally touch one another; Finally in making a Body, the surfaces should wholly touch one another: from all the points would spring one point, and from all the lines one line, and from all the surfaces one surface only. And so a thing indivisible, added to what is indivisible, makes it no greater then it was; nor does it constitute a thing continued, which consists of many parts, each of which is without the rest. Nor do indivisible parts in a thing continued, follow one another as in rank or row: for so there should come nothing of the same kind between: but between any indivisibles, there comes somwhat else of the same kind: for betwixt two points there is a line, in which there must needs be points.

Secondly, If a Line were made of Points, or a Surface of Lines, or a Body of Surfaces; a Line which did consist of ten points, would be longer then that which consists only of nine; and a Surface compounded of ten Lines should be broader then that which does consist of only nine; and a Body made up of ten Surfaces should be deeper then that which is made only of nine. But these should not so happen save for a point, a Line, a Surface. Therefore that point must have Longitude, that line Latitude, that Surface Crassitude or Depth. For in respect of that which is not long, another thing cannot be said to be longer; nor in respect of that which neither is broad nor hath breadth, can another thing be said to become broader; nor in respect of that which hath neither depth nor thickness, can a thing be said to be

thicker then another thing. All which things notwithstanding are manifestly falſ. *Thirdly* it would follow, that there are very many magnitudes, which cannot be divided into two equal portions; which is falſ: ſeeing, it is by the Mathematicians demonſtrated that every continued thing, may be divided into two equal halves, to which it hath a double proportion. For things conſiſting of unequal indiviſibles, cannot be divided into equal parts.

Fourthly, It would then follow, that the Diameter of a Quadrate were equal to its ſide, and a greater circle equal to a leſs, which has the ſame centre: which is abſurd. For if you draw lines from every point of one ſide of the Quadrate, as many as you can poſſibly, to the oppoſite ſide, they will all paſs through every point of the Diameter, nor will there be any point therein, through which they wil not paſs. For thoſe lines fil all the ſpace of the Quadrate. So if from the Centre you draw lines to all the parts of the greater Circle, they will all likewiſe paſs through the leſſer Circle, and therefore the leſs wil have as many points as the greater, and ſo they will be equal. And from theſe inſtances it appears, that a continued thing does not conſiſt of indiviſibles, and therefore that it may be divided into parts perpetually diviſible. For ſeeing it conſiſts of ſuch into ſuch it muſt needs be reſolved.

Yet we are here to obſerve, that a thing may be ſaid to be indiviſible two manner of waies: for a thing is either ſimply ſuch as having no parts: or reſpectively, which cannot be actually divided into ſuch parts, though it contain them, ſuch as are the ſmalleſt things Natural. And touching the former, is our Queſtion; *viz.* Whether a line, conſiſt of points; a Surface, of Lines; a Body, of Surfaces. Moreover we muſt know, that when it is ſaid a continued magnitude may be infinitly divided we are not to underſtand, that it has infinite parts actually or potentially, ſo as by continual dividing they may at length become infinite: but thus we muſt hold, that ſo many parts cannot be taken from a continued magnitude but more will remain. For we muſt not here admit of a real diviſion. For ſince all Quantity adheres in ſome Natural Body, and there are Natural Bodies of the ſmalleſt ſize imaginable, there will be found a quantity actually the ſmalleſt poſſible. But we muſt thus underſtand it; that there cannot ſo ſmal a Quantity be aſſigned, but that our underſtanding can conceive it diviſible into two parts, and again each of theſe into two, and ſo continually deſcending lower and lower. Again, this is to be obſerved, that it is rightly ſaid, that a continued Quantity may be infinitly divided: but it cannot rightly be ſaid that it may be divided into infinite parts. For if we ſay into infinite parts, we ſay not true: for as the continued Quantity is actually finite: ſo alſo its parts are actually finite: and are terminated by the bounds of the whol. But this is true, that a continued magnitude is apt to be divided infinitely, that is to ſay, in dividing you cannot come to any thing but what may be divided again. And hence it does not follow, that what is continued in magnitude has infinite parts. For every whol is eſtimated by ſuch parts, as have a certain magnitude: and ſuch in every continued thing are finite: but thoſe parts in reſpect of which a continued Quantity is ſaid to be infinitely diviſible are not actually of any determinate magnitude.

Hitherto has been ſhewed that a continued Quantity in a Body Natural, is not compounded of indiviſible parts, and therefore is infinitly diviſible, although it be never actually divided into infinite parts; ſeeing Natural things have determinate bounds of their greatneſs or ſmalneſs. Touching which, ſeeing there is ſome controverſie amongſt Authors, I ſhal ad ſomwhat to what has been ſaid, and make inquiſition into the greateſt and ſmalleſt Natural things. Wherein that I may proceed the better, I muſt premiſe ſome things.

In the *Firſt place*, Although the notions of *Greateſt* and Smalleſt, are transferred from Quantity to other things, as alſo Qualities and motions are; yet that in this place we ſpeak properly of Natural ſubſtances. For touching them the Queſtion is, whether they certain bounds and limits ſet to their Quantity. *Secondly*, That this Queſtion may have a manifold ſenſe: as a man may ask both whether there be in Nature a greateſt and ſmalleſt ſubſtance, then which now can be greater or ſmaller: and whether Nature have ſet bounds of Quantity, ſo that ſhe hath not of her ſelf power, to make things bigger or leſſer? Moreover, it may be further queſton'd, Firſt whether there be abſolutely the greateſt and ſmalleſt thing poſſible,

in

in the Universe? Secondly, whether in every sort of Natural Bodies both simple and compound, and of Homogeneal mixt Bodies as wel as Heterogeneal, and of animate as wel as inanimate, there are certain and set bounds of Greatness and smalness? Thirdly we are to observe that the terms or bounds of greatness and smalness are twofold; some intrinsecal which things receive from their own Nature: others extrinsecal, which are by others externally prescribed to things. Fourthly, That the greatest and least are so termed Positively or Negatively. Positively that is the greatest thing, which is greater then all others, and to which nothing is equal; and the least contrarily Negatively, that is greatest, then which nothing is greater, though there be somwhat equal. And that is Negatively the least, than the which nothing is lesser, though there may be somwhat as little.

There is Actually in the whole universe and in every sort of natural things, somwhat greatest & somwhat least.

These things being premised, thus we conclude. I. In the whol Universe, and in every sort of Natural things, there is actually somthing which is greatest and somthing which is least. For unless there were somwhat greatest and somwhat least, in the whol world, and in every sort of things, either positively or Negatively: there might be a greater then any that is never so great, and a less then any that is never so smal, and so there should be actually in Nature an infinite multitude of things. But that that cannot be, shall be hereafter demonstrated. The same does also hereby appear; Seeing all accidents do follow the substantial Form: and every Natural Body, hath a Form actually determined: therefore every Natural Body must also have accidents determined and a limited Quantity. And, indeed, of all Bodies Heaven is the greatest, because it containes all things: but what the smalest thing is, we cannot peradventure determine. Howbeit *Aristotle* in his 5. *Book of the History of living Creatures Chap.* 32. Writes that in old Wax, as in wood, a white living Creature is bred, which of all Live-wights may be, counted the least, the name whereof is *Acari.*

II. In every sort of Live-things, there are intrinsecal bounds of greatness and smalness, without which Nature cannot produce nor conserve Living things: so that no Individual or Particular Creature of that sort, may be produced and conserved, which either exceeds that term of Magnitude, or fals short thereof. For examples sake, in case the greatest Height of a Man be four Cubits, the smallest one Cubit: there can no man be generated that shall prove higher then four Cubits, or lower then one Cubit: but all shall be either of four, or of three, or of two, or of one Cubit, or of some other measure betwixt four and one. And thus does *Aristotle* determine in his 1. *of Physicks, Chap.* 4. *Text* 36. *in the* 2. de Anima, *Chap.* 4. *Text* 41. *in the* 4. *de Gener. Animal, Chap.* 4. *in the* 7. *of Politicks, Chap.* 4. And Reason perswades the same. For since augmentation or growth is determinate: and quantity is acquired by augmentation, it self must therefore be determinate. And that Augmentation is definite, does hereby appear, because it is an action of the Augmenting faculty, which is determinate as all other faculties of the Form are: the instruments also are definite or determined. For the very Natural Heat is limited, and becomes every day more remiss, Yea, and is at last extinguished. Yea, and al the other. Instruments are also limited. Nor is experience against it. For we never heard of a Dog born as big as an Elephant, nor grown to that greatness, nor of an Elephant born no greater then a Puppy-Dog. Howbeit, hard it is to set down and observe the terms, in every species. For they have sundry variations, and more in one sort, then in another. Amongst Men there is a great diversity of Magnitude; a greater amongst Dogs; but not so great amongst Cats, and Birds and other Animals.

III. But the Elements have no determinate magnitude of themselves and intrinsecally, but from without. For the Elements of themselves, if they had matter enough; and there were no outward obstacle might be augmented indefinitely. For look how much greater Bulk the fire gains, by so much the more efficacy it has, the more it resists contraries, and turnes them into its own Nature. But their magnitude is limited by the things which contain them, and in respect of the *Materia Prima*, or first matter. For seeing the bulk of the first matter is finite, the Elements cannot be infinitely augmented.

IV. And Because the Elements do likewise change their Quantity, by Rarefaction and condensation; touching *that*, we are likewise to know: that of their own

nature, they are in this point limited. For they cannot be condenſed or rarefied, after every ſort and manner, without being corrupted. And experience does witneſs, that the earth is never ſo rarefied as the fire, nor the fire ſo condenſed as the Earth. Yea and when the Air is too much condenſed it is turn'd into water; and the water being too much rarefied is changed into Air.

V. Touching mixt things without life, which exiſt by themſelves, and are homogeneal, we are to judg the ſame in this point, as of Elements: and of things Heterogeneal the ſame as of living things.

VI. Finally, as concerning the Parts which are in the whol, thus we are to hold. If they are heterogeneal, they have determinate Limits of their greatneſs and ſmalneſs, inaſmuch as they are parts and Inſtruments of living things, which have a certain magnitude. But if they be homogeneal, there cannot be aſſigned a ſmalleſt, nor are they contained in any ſet limit of ſmalneſs. For ſeeing the Form of Fire, has the ſame reſpect in all its parts, and that it is extended according to the extenſion of the matter: after the ſame manner as there cannot be aſſigned the ſmalleſt inexiſtent Quantity; ſeeing every continued thing is infinitly diviſible: ſo there cannot be aſſigned any portion of fire, than which there is not a ſmaller in the ſame fire.

Whether there is any thing infinite in nature?

And ſo much may ſuffice to have been ſaid of Quantity; we are now to treat *de finito et infinito*: touching that which is finite, and that which is infinite. For theſe are proper adjuncts of Quantity: and they are likewiſe adjuncts of motion and time; ſeeing any and every of theſe is either finite or infinite. And in the firſt place, let us conſider whether there be any thing infinite in nature. And although there be ſundry ſignifications of this term Infinite: yet the chief ſpeech in this place, is concerning that which is Infinite in Quantity, and indeed of that which is actually infinite; and the Queſtion is, whether there be actually in nature any thing, which is infinite, either in magnitude or in number: or whether there be any natural thing, whereof when you have taken never ſo much in Quantity, you may ſtil take more, which is the definition of that which infinite. Now it is by the Phyloſopher rightly affirmed, that there is no ſuch thing in nature, for theſe Reaſons. For that, in general there can be nothing infinite, is from hence aparent; inaſmuch as all things produced by and depending upon another, are defined and circumſcribed by their own bounds and limits, nor can they by any means poſſible be infinite, But of the ſorts of things, it may alſo eaſily be proved, that there is no infinite multitude. For ſeeing one ſort does alwaies exceed another in perfection, if the ſorts of things were infinite, the world would be infinitely perfect, and would have in it infinite degrees of perfection: which is a thing Impoſſible. For every thing produced by another, and depending upon another, has a participated and therfore a finite perfection. But the world is produced by God and depends upon him. Therfore it has a participated and finite perfection, and is ſeparated from God in perfection, from whom it has received its perfection; and therefore, it is neither infinite, nor does it contain infinite ſorts of things.

Nor is there any thing infinite in Magnitude. For, in the firſt place, if there were a Body infinite in magnitude, there could be no other in the world but that; for ſeeing it would require an infinite place and would fil the Univerſe, it would leave no room for any other body. Moreover, every thing that hath quantity, hath neceſſarily figure. But that which is infinite can have no figure. Moreover it muſt conſiſt of all its parts either finite, or infinite, or of one infinite and the reſt finite. But none of theſe is poſſible. For that which is infinite cannot ariſe out of finite parts. Nor can the ſecond or third hold, for one infinite would fil all place and dimenſion, and would leave no place for the reſt of the parts: and if it ſhould have a Quality contrary to the reſt, it would turn all the reſt into its own nature.

And as we deny that there is any thing actually infinite, ſo we grant there is ſomwhat potentially infinite. And firſt in the continued Quantity, which is in a poſſibility of infinite diviſion, as was ſaid before: and ſecondly in number, which may be infinitely augmented. For there cannot be imagined ſo great a number, but that more may be added thereunto. Finally in time and motion, which are ſucceſſively infinite. But concerning that which is Infinite, I ſhal ſay no more, only conclude with that ſaying of *Piccollimineus* in his 1 *Book of common Affections of*

natural

natural Bodies, Chap. 3. That which is Infinite, as Infinite is unknown, and whileſt we know that which is infinite, we know that which cannot be known.

Chap. 6. *Of the Qualities in general.*

AFter Quantity *Quality* ought of right to follow, and we muſt ſay ſomwhat of the Phyſical Qualities in General. For as all natural Bodies have Quantity by reaſon of their matter: ſo in regard of their Forms they have Qualities. Now Quality thus conſidered in general, and as it belongs to all natural Bodies, is an adjunct of a natural Body, flowing from the form thereof, by which the form is efficacious, and a natural Body apt to do or ſuffer. For the forms of natural Bodies do not act nor work immediately, like God, but by the Mediation of Accidents and Qualities. And though the form be the primary Principle of Operations, and the Qualities are the immediate and next principle of the Operations, yet are they leſs principal, and only Inſtrumental. And the forms in their actings do uſe the Qualities as Inſtruments: but the Operation of the Qualities ſprings from the virtue of the Forms. And ſo becauſe nothing is idle in nature, but every natural Body acts, therefore every narural Body muſt alſo be furniſhed with its Qualities,

Quality what?

Now theſe Qualities are divided in reſpect of our knowledg into *Manifeſt* and *Occult*. The manifeſt are thoſe, which eaſily evidently and immediately, are known to, and judged by the Senſes. So light in the Stars, and Heavineſs and Lightneſs, being firſt Qualities, are manifeſtly obvious to the Sences. But occult or hidden Qualities are thoſe, which are not immediately known to the Sences, but their force is perceived mediately by the Effect, but their power of acting is unknown. So we ſee the Load-ſtone draw the Iron, but that power of drawing is to us hidden and not perceived by the Sences.

Qualities divided.

So there are many Influences of the Heavens which we know by their Effects upon theſe lower Bodies, but cannot by our Sences perceive them.

Now from the Qualities of natural things ariſe their conſent and diſſent, and things like have a mutual appetite one to another, contraries have an averſneſs one from anorher. Hence fire is eaſily united to fire, fat things to fat things; but fire ſhuns water, and fat things ſhun fire. And this is the manifeſt conſent and diſſent of Natural things.

But from the hidden qualities there ariſe Sympathy and Antipathy ſo called; when natural things are carried one to another by an hidden Love; or have a natural abhorrency one from another, as ſome cannot endure a Cat to be preſent, no not ſo much as to look upon the Cat, and others have the like abhorrency from other things. And becauſe this ſame hidden action is moſt conſpicuous in a Load-ſtone, other ſuch like Actions are therefore termed magnetical.

But of the ſeveral ſorts of Qualities, we ſhall hereafter treat in their proper places.

Chap. 7. *Touching Place.*

THat which is commonly ſaid of Time; *We live in time and yet we know not what time is*, may be as truly ſaid of Place: we are in Place, yet are ignorant what Place is. For the Queſtion about the nature of Place is ſo intricate, that the moſt acute Phyloſophers are herein at a ſtand, while the Queſtion is, Whether Place be the ſurface or outmoſt bounds of the Body containing: or a ſpace equal to the Body placed,

Both Opinions have patrons and defeuders of no mean rank. For the firſt is the opinion of *Ariſtotle* himſelf, and the moſt of his Interpreters: the latter was famous in *Ariſtotles* time and was maintained by the Stoicks, the Academicks and by *Galen*; and by *Phyloponus* amongſt the ancient Peripeticks; and amongſt late Writers, by *Julius Cæſar Scaliger* and other renowned Men.

And though I do not take upon me to compoſe ſo great a controverſie betwixt ſuch famous men, nor think that it is fitting to deſert the Prince of Phyloſophers, unleſs

whether Place be a Surface?

unleſs upon a very weighty occaſion: yet ſeeing the opinion of *Ariſtotle* is laden with very great difficulties, in the mean while, til ſome body ſhal anſwer what is brought againſt his opinion (for I beleeve no man has yet given a ſolid anſwer thereto) I muſt take the adverſe ſide: eſpecially ſince it is wel known that the very Interpreters of *Ariſtotle* have confeſſed, that the other opinion is not improbable, nor has been by any ſufficiently confuted, and that there is no demonſtrative Argument to the contrary; and that the opinion of *Ariſtotle*, is only probable, but not neceſſary: and it is very wel known, that moſt men have been moved by Authority rather than Reaſon to defend the opinion of *Ariſtotle*: which one man, *viz.* *Didacus Maſius* does plainly confeſs, when in his Commentaries upon the 5. *Chap.* of the 4. *Book of Phyſicks*, he thus writes: *But I* (ſaies he) *unleſs I were hindered by the Authority of* Ariſtotle *and* Thomas Aquinas, *ſhould moſt willingly imbrace that opinion concerning Space, which we may eaſily perceive, if diligently we ſhal weigh the foregoing Arguments and what has been ſaid touching the Nature thereof, that it is both more eaſie to be underſtood, and has fewer objections againſt it. But becauſe we muſt ſubmit our underſtandings to* Ariſtotle *and St.* Thomas, we are forced to confeſs, that Place is a Surface and not a Space, becauſe theſe moſt grave Phyloſophers, have ſo determined.

The Properties of Place.

But that I may not ſeem to have done any thing without reaſon, wherein I imitate *Ariſtotle*, I ſhal propound the chief proprieties of Place, and examine which do truly and properly belong thereto; that from thence it may appear, which of theſe opinions is moſt probable. *Ariſtotle* in the 4. *Book of his Phyſicks Chap.* 4. *Text* 30. tels us, That theſe are the properties of Place. 1. To contain the thing placed, or whoſe place it is. 2. To be no part of the thing contained, which property ſome joyn with the foregoing, thus: a place does ſo contain the thing placed, as to be no part thereof. 3. That the place be neither greater nor leſſer, than the thing placed. 4. That the place is ſeparable from the thing placed; or as ſome read it, that the place cannot be without ſome body, but may be without this body or that. 5. That all place is upwards or downwards. 6. That every body is naturally carried to its own place, and is diſpoſed to reſt therein. Howbeit, ſome joyn this with the fift. From other places, Authors gather more properties: for they ad, 7. That it is a property of Place to draw to it ſelf the thing placed: which they would draw out of the 4. *of his Phyſicks, Chap.* 1. *Text* 4. 8. That the place has a faculty of generating, conſerving, and perfecting the thing placed: which they draw from the 4. *of his Phyſicks ch.* 1. *Text* 4. *Chap.* 5. *Text* 48. 49. from the 4. *de Cælo Chap.* 3. *Text* 23, 24. from his 8. *de Hiſtoria Animalium Chap.* 28, 29. 9. That the place gives diſtinction and unity to local motion. 10. That Place is immovable, 4. Phyſ. Chap. 4. Text 41. 11. Out of *Pſellus* they draw this property: that a Place is neither aboliſhed, nor does periſh, though the things which are therein, may be aboliſhed.

And theſe are the chief Properties of Place which we meet with in Authors: betwixt which we muſt nevertheleſs diſtinguiſh. For, as to the firſt, ſecond, third, fourth, ninth, tenth, eleventh, they are ſimply neceſſary to a place, nor is there much doubt concerning them. As for the reſt, we muſt ſee in what ſence they may be admitted, and we muſt enquire, what agrees with a place in it ſelf and as it is a place, and what by accident: in which point there is no ſmal confuſion in Authors.

How place and Situation diffe r?

In the firſt place, that is to be noted, which *Scaliger* does hint, in his 3. *Book* de re Poetica *eſpecially in the* 120. *Chap.* nor has it been omitted by others; that we muſt diſtinguiſh betwixt a place ſimply ſo called, & as it is an affection of a Body natural in general; and between *Ubi* and *Situs*, which is not any place, but one affected with certain conditions, which they are nevertheleſs frequently accuſtomed to cal Place. Hence 'tis a common ſaying, that the place of light things is above, and of heavy things beneath: becauſe in the middle of the world there are qualities by which heavy things are amicably cheriſhed; and about Heaven there are qualities that cheriſh light things: which Qualities nevertheleſs do not neceſſarily belong unto the eſſence of place. For even the fire in the Bowels of the Earth is in a place, though not favorable thereunto. Hence alſo *Ariſtotle* in his 8. *B. de Hiſtoria Animalium, Chap.* 19. 28, 29. *Probleme* 15. *Section* 14. and *Pliny* every where, ſaies that the natures of plants and Animals are divers according to the variety of places wherein they are

and

aud that ſome places are convenient and others inconvenient.

Since therefore theſe are reckoned amongſt the proprieties of place: that every thing is carried to its place; that the place does allure and draw to it ſelf the thing placed; that the place has a power to generate, conſerve and perfect the thing placed therein: we muſt know, that all theſe properties do not agree to a place, as it is a place. For ſeeing a place as *Toletus* ſaies, is formally Quantity: it is not of the Eſſence thereof to be a Cauſe. For Magnitude as they ſay, is not the efficient of an accident; which *Scaliger* alſo intimates in his 5. *Exercitation, It is not true* (ſaies he) *that bodies are preſerved by their place, but by their form.* And if a Place as a Place, and therefore not a proper one, ſhould conſerve: the Elements would not ſeek to get out of that place into their proper place. The Elements therefore are not preſerved by their place; but by their *Ubi*. *Scaliger* in the *ſame Exercitation, Section* 5. But ſo far the Place is ſaid to preſerve the thing placed, inaſmuch as the body there placed, does conveniently receive the Qualities of the Heavens and Elements which are moſt agreeable thereunto: and inaſmuch as Qualities friendly to the thing placed, are in the Subject which is about the place.

And therefore, ſeeing in the ſearching out of the nature of things, that which is by it ſelf, muſt be carefully diſtinguiſhed from that which is by accident: we do here underſtand the term Place, not in the latter, but in the former Senſe: Nor do we allow of that ſaying, that only the Elements are in a Place. For we do not here ſeek after the Adjunct of ſome ſort of natural Bodies; but our Enquiry is, what *Place* is in it ſelf conſidered, and as it agrees to al natural bodies in general, and to al their ſorts as a proper adjuuct.

Whether the Properties of place do beſt agree to a Surface or a ſpace?

We are now in the next place to conſider, whether the genuine Properties of place do beſt agree to the Surface of a body containing, or to the Space commenſurate with the thing placed. And that we may begin with immobility; *that* is a moſt true propriety of Place, and by *Pererius* his confeſſion, though it make againſt himſelf, it is an eſſential Propriety thereof, even as riſibility or a diſpoſition to Laughter is an eſſential propriety of Mankind; and as *Ægidius Romanus* ſaies *Lib. 4. Phyſ. 1. 41. Sect. 7.* the very formal being of a place. To the aſſerting whereof, though there were no other Reaſon, this might ſuffice, that all Men whatſoever their opinion is concerning Place, do herein agree, that a Place muſt be immediable, and every one endeavors to accommodate this propriety to his Place. And verily he that takes away the immobility of Place, he takes away local motion and the diſtinction thereof. For that which is moved, of neceſſity leaves one place and goes into another: which could not be, if the place were moved with the thing.

From this Propriety therefore we conclude: ſeeing place is neceſſarily immovable, and the ſurface of a body containing is not immovable: that it is no Place. For ſuppoſe a Tower or a Pillar erected, or a Tree growing up in the Air, or ſuppoſe an Hill ina River, or in the Air, at every moment as the Wind blows and the River runs, their place wil be changed, which is againſt the Nature of Place. Yea and this great Abſurdity wil hence follow: that one and the ſame body, fixed in one and the ſame ſpace, quiet aud without motion, ſhall have every moment a new place, and ſo be in an innumerabe company of places.

In this Argument the maintainers of a Surface to be Place, are variouſly perplexed, as we may ſee in *Pererius* Book 11. Phyſ. Chap. 2, 3. and *Tolet.* Book 4. Phyſ. Queſt. 5. And *Pererius* himſelf demonſtrates that the anſwers carefully ſought out by *Scotus* and *Aquinas* are not ſatisfactory. And it wil be worth our while to conſider whether he brings any thing more to the purpoſe, ſeeing many affirm that he has anſwered all Objections. Now this is the judgment of *Pererius*: Firſt, he ſaies the word Place is uſed in common and vulgar acceptation for ſcituation and poſition; and 'tis commonly ſaid a thing has this or that place, meaning that it is ſo or ſo ſcituated; and, therefore a thing may change its place two waies, either actively or paſſively: Actively, when it paſſes out of one place into another, leaving the place wherein it was before: Paſſively, when the thing remains immovable, but the place about it is changed. He ſuppoſes therefore, that a Tower, a Pillar, or Mountain, about which ever and anon the ſurface of the Air or Water is changed, are not properly in the ſame place: yet they remain in the ſame place, by place intending ſcituation: or they remain in the ſame place actively; becauſe

becauſe theſe bodies themſelves do not paſs from place to place: yet they remain not in the ſame place paſſively; becauſe the Surface of the Air and water compaſſing the ſaid bodies, does not remain the ſame in number, but is ever and anon changed. This is *Pererius* his defence, which whether it be not contrary to al Reaſon and ſenſe, let himſelf judg. But I would firſt have *Pererius* reconcile this propoſition which is in his 11.B. ch.3. p.615. The Surface of the Body containing, which is of the Eſſence of place, is not alwaies the ſame in number about the ſame thing placed but is ever and anon varied; with that, in his 1.ch.p 607. immobility is eſſential to place, becauſe it is an eſſential property thereof, as riſibility is of a Man, and becauſe immobility is uſed in the definition of Place, inſtead of an eſſential difference. Can Surface be of the eſſence of place, and yet not be immoveable which is an eſſential propriety of place? Again I grant, that the term place is frequently uſed for the Scituation and Poſition of a Natural Body, and allow ſuch a ſpeech be proper enough: Yea, and if ſo be a thing remains in the ſame Scituation, I aver againſt *Pererius*, that it remaines in the ſame place; for Scituation alwaies preſuppoſes place, and it ſignifies the relation of the thing placed to the place. And therefore Natural bodies when they change their place, do alſo change their Scituation. And it is, doubtles, a great Abſurdity to ſay, that a thing not moved with any local motion ſhould change its place. For a new place is gained only by local motion: and that which changes place, is locally moved, and by local motion, we are bronght to the knowledg of place, as may be ſeen in *Ariſtotle* 4. *Phyſic. Chap.* 4. *Text* 32. And therefore *Tolet* rightly ſaies: If I ſtir not, and the Surface about me be changed, it may not be granted that I am not ſtil in the ſame place. That is therefore a weak defence, which is made by diſtinguiſhing betwixt active mutation of place and paſſive. For ſeeing to change place actively, is for a body to be transferred out of one place into another; to change place paſſively muſt be, for the Place to come unto and be moved to the thing placed: then which, what is more abſurd? Nor is *Ant. Ruvius* more happy in his ſolution, Book, 4. *Phyſ. Queſt.* 3. who confeſſing, that this Argument is ſo difficult, that in regard of the difficulty thereof, Authors have been divided, as to the manner of attributing Immobility to place; and examining and rejecting the opinions of others, he is at laſt forced to confeſs ingenuouſly; that it is impoſſible that the whol Nature of Place, ſhould conſiſt in a Surface, and that *Place* ſhould be immoveable; ſince 'tis evident, that the ambient Surface is frequently varied, and that therefore place requires ſomwhat, in reſpect of which it may be immoveable. And at length he is fain to fly to this, that Particular places, are therefore immoveable, becauſe they are parts of total place, or parts of that whol ſpace, real or imaginary, which is comprehended under the compaſs of the Skies. Whereby to ſay the truth, he ſo leaves *Ariſtotle*, as to joyn with them that ſay place is that ſpace, which every Body fils.

Another propriety of place, is to be equal to the thing placed. But the Surface is not equal the to thing placed; and therefore it is not the place. For a Surface hath only two dimenſions, but a Body three. Nor does *Pererius* his anſwer remove the difficulty: *viz.* That the place is equal to the thing placed, becauſe the convex Surface of the thing placed, and the hollow Surface of the thing containing are equal. For the Queſtion is not about the Quality of the Surfaces of a thing containing and a thing contained: but touching place and the thing placed. Now Bodies are placed, and not Surfaces. And therefore it is neceſſary, that a place, be not only equal to the Surface of the thing placed, but to al the dimenſions thereof: for otherwiſe the place ſhould not be equal to the thing placed. For a Line is not ſaid to be equal to a Surface, nor a ſurface to a Body; but a Line to a Line, a Surface to a Surface, and a Body to a Body.

A ſurface does not agree to al Bodies.

I ſhall not compare any more proprieties of a place with a Surface. For what hath been already ſaid, is more then thoſe can anſwer, who wil have place to be a Surface. Yet one thing I wil add. *Place* is a common Adjunct of al Natural Bodies, and ought to agree to all. But the Surface of a Body containing, does not agree to all Bodies. Therefore it is no place. For the Higheſt Heaven, hath no Surface of any Body to compaſs the ſame about: whereas it is nevertheleſs a Body, and is locally moved; and therefore requires a place. For whereas ſome think it is no abſurdity to ſay, that the higheſt Heaven is in no place, nor that every Natural Body hath a place: this ſeems unreaſonable. For that every Body

The higheſt Heaven is in a place.

is in a place, and that a Body cannot be without a place nor a place without a Body, is the Assertion of the graveſt Phyloſophers *Avenroes*, *Johannes Grammaticus*, *Porphyrius*, *Marſilius Ficinus*, and very many more both antient and late Authors. Nor does *Ariſtotle* ſeem to diſſent in this point, in the 4. *Phyſ. C.* 1 *Text* 6. *and* 1. *de Cælo, Ch.* 7. *T.* 69. And that aſſertion is not void of reaſon in the 4. *Phyſ. C.* 7. *T.* 1. *Every thing that is, is ſomwhere. and that which is not, is no where, and that which is no where, is not.* Natural Bodies, are real beings, and therefore they are ſomwhere. Now there are three manner of waies, whereby a thing may be ſomwhere, Repletively, Definitively, Circumſcriptively, or Locally. But Natural Bodies cannot Naturally be ſaid to be any where in the two firſt manners. For it belongs only to God to be Repletively any where: who as *Damaſcrin* truly writes in Book 1 Ch. 16. *is totally every where, totally in all things, and totally above all things.* Or as *Scaliger* in his 1. *de Plantis*; *who is by all things, above all things, in all things, before all things, after all things, High, Glorious, Immenſe, Incomparable, Incomprehenſible.* And to be any where definitively, is ſaid of Angels. And therefore Naturally bodies as ſuch, where ever they are ſaid to be, they are ſaid to be there Locally: and by Reaſon of their Circumſcript and Determinate dimenſions, they are in a Circumſcribed and Determinate ſpace. Hence *Du-Rand* ſaies wel in 4 *Sect. Diſtinct.* 44. *Queſt.* 6. *In this reſpect only a place is poſſeſt by the thing placed; becauſe the thing placed hath within the place, the diſtention of its parts. Since therefore this is eſſential to the thing placed, as it has Quantity, it is impoſſible the thing placed ſhould be in the place, and not take the ſame up.* And a little after: *If a Body be locally in a place, it cannot be, but it muſt take the place up: becauſe to take a place up, is to have in the place parts diſtant in poſition one from another and from all other Quantity: and that is nothing elſe, but to have Quantity.* Alſo there is a moſt elegant place to be ſeen in *Scaligers* 56. *Exercitation, Sect.* 6. wherein he ſhews, how the place is neceſſary to the thing placed. And in very deed, motion does ſufficiently teach, that the Heaven is in a place. For ſeeing every thing that is moved, is moved in its place, by local motion: and the Heaven is moved with local motion; we muſt by no means deny that it is in a place. Nor can local motion be imagined without a place, Yea verily, though the Heaven were without motion; yet the Heaven of its own Nature is in a place. For ſeeing place belongs to bodies not only becauſe of their motion, but that Natural Bodies are in place when they ſtir not; what ever you will aſſigne to be the cauſe why Natural Bodies are in place, it wil be found alſo in the Heaven: ſeeing it is a Natural Body.

God is preſent repletively.

Angels definitively

Bodies Natural Circumſcriptively or locally.

And whereas the Authority of *Ariſtotle* is objected, who in the 5. of his Phyſicks Chap. 5, Text 43. delivers this rule of knowing what Bodies are in a place and what not; *viz.* That Body is in a place. without which there is another Body that containes it: but that is not, without which there is none: this Authority does not hinder us at al. For *Ariſtotle* did build this rule upon his preſuppoſed definition of place; which definition falling, this rule fals: and withal the argument drawn therefrom. *viz.* That the Heaven is not in a place; becauſe place is the Surface of a Body containing: but without the Heavens there is no Body. For here the queſtion is beg'd: and it is more doubted whether place be a Surface, then whether the Heaven be in a place.

Seeing therefore, for theſe and many other Reaſons, that Opinion which makes place to be the Surface of a Body containing, cannot poſſibly ſtand: and by confeſſion of all Peripateticks, ſuch a thing as place there is, and it is diſtinct from the thing placed; I do aver, that a place is all that place long, broad, and deep, which the Body placed does Occupy and this ſpace is a thing different from the Bodies themſelves. For though you ſhould imagine al the Bodies in the univerſe to be removed, there would remaine a ſpace, long, broad, and deep; which nevertheleſs, is not at any time actually without Bodies: but the whol Univerſe fils this whol ſpace, and every part of the Univerſe challenges a part of the whol ſpace, equal to it ſelf.

Place is a ſpace not a ſurface.

Now that there is ſuch a ſpace is apparent out of the 4. of Phyſicks, Text 3. and the change of things out of one place into another ſhews as much. For there where Water now is, *viz.* In the Veſſel, when that is powred out there will be Air, or ſome other Body of equal dimenſions wil poſſeſs the ſame place. Nor does this happen only in reſpect of Surface. For unleſs a Veſſel be emptied according to al

whether there is ſuch a ſpace.

dimensions; another body cannot go into it; and the thing placed fils its place according to the three dimensions. Let there be two Vessels of equal Magnitude and Capacity, in respect of their concave surface; and fil the one which shal have nothing in it but Air, with Water: and afterward pour the same water into the other, in the middest whereof a stone shal hang by a thred; the water will not all be contained, by a vessel of the same capacity and surface. What is the cause hereof? If a surface be place, what is the reason, that, seeing there are in these two Vessels equal surfaces, and consequently equal places, they do not receive a Body placed of the same size? Namely, because a place is to be defined and estimated not according to the surface, but the whol space and profundity, according to which the thing is placed. And that two bodies cannot be together, is not therefore, because of the surface of the Body containing, but because each body requires a peculiar space for it self to exist in.

The proprieties of place agree with space

And that this space is place, does hereby also appear, in that all the genuine proprieties of place do agree thereunto; and by this opinion, those great difficulties are avoided, which vex other opinions. For the space containes the thing placed therein, and is equal thereunto: and is never without one body or other; but it may be without this Body or that: it is immoveable, nor when any Body is removed, does the space wherein it was move with it: but the Body passes out of one part of this space into another. Also by this opinion, that most difficult Question, in the answering whereof, one side is much puzzled as may be seen in *Pererius B. 11. Ch. 8. Tolet B. 4 Phys. Quest. 7. Colleg. Conimbr. Book, 4. Phys. Ch. 5. Qu. 2. Art. 12. viz.* How the uppermost Heaven is in place, may easily be answered. For it

The Heaven is in its space.

is in its space which it occupies, as *Scaliger* rightly saies in his 5. *Exercitation, Sect.* 3.

what this space is?

Now what for a thing this space is, is not very easie to determine. Yet we must not therefore deny that there is such a thing. For these are distinct Questions, whether a thing be and what it is, And if we should deny there were any thing but that the Nature whereof is perfectly known to us: we must deny against manifest reason the beings of many things, because their Essence is hid from us. Howbeit, when they who deny the uppermost Heaven to be in a place, shal explain what that same *Ubi* is, in which the upmost Heaven exists and is moved: it will be easie to explain what this space is. Or let them tel us, what is the Essence of the first matter, and we shall with the same ease unfold the Nature of space. For if from a Natural Body I remove in my thoughts all the form, and all the adjuncts proceeding therefrom, as *Aristotle* himself in the 7. of his *Metaphysicks, Ch.* 3. *Text* 7. Describes it by the negation of all things: what I pray you will there remain? And shall we therefore, because we cannot sufficiently understand the Essence thereof, and can only comprehend it by a bastard kind of reasoning, cal it only an imaginary kind of thing? By no means. Even so, though our mind cannot conceive space, save by the denial of al Bodies: it does not therefore follow that it is nothing, or nothing different from the Body. For if this and this and that and that Body, may be removed from this space; doubtless all these Bodies, wil be different from this space, and the Space from the Bodies.

Yet I shal produce what Authors think therof. *Proclus* held this space to be a body animate, indivisible, immovable, immaterial. Others wil have this space to be nothing real, but of it self an emptyness, or privation of a Body, which yet it can receive. Others say, this space is an accident, *viz.* A Quantity, long broad and deep: not as *Epicurus*, existing by it self without any Body, but alwaies conjoyned with some Body. *Jordanus Brunus Nolanus*, takes it to be a fift kind of Cause. Which seems to have been an old opinion. For they relate from *Albertus Magnus*, that the Peripateticks did reckon place amongst the Principles of Nature: from whose opinion, *Franciscus Patricius*, seems not to differ, in his *Book de Spatio Physico.*

Among these opinions, because the three last have renowned Men for their Authors, I am minded to propound them according to their Authors intents. Not but that I know the Objections which those opinions also are liable unto; seeing it is much easier to overthrow *Aristotles* opinion of place, then to tel what space is: but to the intent that the diligent searchers of Nature, may have hereby an occasion to think of the matter. For as *Aristotle* wisely writes in the 2. *of his Metaphysicks Ch.* 1. *'For we are not only bound to thank them that have so writ as to satisfie us with their opinions, but them also who have spoken but superficially, for even these men also advantage*

tage us by affording matter to exercise our wits. And as *Scaliger* saies well, in *his first Book of Plants, A studious Person should pass nothing over, which may offer it self as an occasion of fuller contemplation.*

Julius Cæsar Scaliger therefore, in his 5. *Exercitation Sect.* 9. saies, that th s Space is a Vacuity filled with Bodies, or a *Vacuum* wherein is a Body, whose Nature is such, that when one Body gives place to another, there is a *Vacuum* or Empty space made, that the other Body may come in as Privation is a Vacuity of the Form to be introduced: and nevertheless is by *Aristotle* placed amongst the Principles of Nature. For as *Epicurus*, in *his Epistle to* Herodotus *in* Diogenes Laertius, *writes*; If *that were not, which we call emptyness or space, Natural Bodies would no have where to be, nor would any thing be moved, as now we see things are moved.*

Now the last opinion save one *Phyloponus* did long ago stifly maintain, and some even in this Age do account it no absurdity. Nor do they conceive, that which is objected against this opinion, much to hinder the same: *viz.* if space it self be long, broad and deep, and another body should be placed therein, there would be penetration of dimensions. For two Bodies are not hindred to be in one place, in respect of Quantity alone; for so a Body of the Predicament of substance could not be with a Body of the Predicament of Quantity; whereas nevertheless these two are one and the same in number and subject; but beceause of the corporeal matter. And we must difference a Body extended and measured out, from the extension and measurement it self: whereof the former is a corporeal substance, the latter an accident: both which are nevertheless termed a body, by reason of that penury of words in this Case. Hence *Johannes Grammaticus* himself saies, that *a Body is not a threefold dimension, but that substance to which the said dimension is inherent as in a subject.* Nor does any remarkable absurdity follow from this opinion, *viz.* that an accident should pass out of one subject into another. For that passage only of a Form or adjunct out of one subject into another is impossible, whereby an accident or Form being one in number, does leave its whole subject, and pass into another: but if a substantial or accidental Form, does not go out of its whol subject, but remain therein, it is not absurd that it should go out of one part into another. Therefore every dimension may receive any Body, as one part of the dimension of the whol Universe, may contain also some part of the Universe in it. *What a Body is?*

Finally, Neither does that follow from this opinion, that there can be places actually infinite, or that a place can have a place, or that a place, can change its place, as it is in the 4. *of Physicks Chap.* 4. *Text* 37. For the parts of water are in water, as in their whol, and in space as in their place: which if they are finite, they have finite Spaces answerable, if infinite, they have infinite. Moreover since all the water changes place, the parts also of the water change place: yet place does not change place, nor is there a place of place. But as the whol and parts are transferred: so also the whol and parts change place: but the space which is part of the Universal space, remaines immovable. For neither a River, or Heaven, or a Vessel, or any such thing is a place, but that space wherein a River, Heaven or a Vessel or any other thing is contained.

Didacus Masius out of *Philoponus* and other Defenders of Space, does thus describe the nature thereof. The nature thereof is a body: for it consists of three dimensions, Longitude, Latitude, and Profundity: yet is it immaterial; because it has no matter nor form. For it ought to penetrate the thing placed, according to all its dimensions: but if it were material it could not penetrate. And therefore it is also indivisible; because from it no parts can be taken away. For division can only have place in such things as consist of matter: and moreover it is separated from the Bodies placed therein. For the same space in number which contains the Wine in the Flagon, the same receives Air, and when that is gone Water or some other Liquor. And therefore it receives not its individual nature from the Bodies, but of the bodies within whose sides it is contained, as the space in the Flagon from the Flagon; that in the Air from the Air. Moreover it is affected with no qualities; because it is neither white, nor black, nor hot, nor cold. And therefore it seems rather a Mathematical Body, separate from all sensible matter, then a Physical and natural body. Also it penetrates al bodies which it imbraces in its Lap, yet without division, as sweetness penetrates through the whol Body of the Milk

without dividing the same. For so it penetrates all bodies which it contains, as to fil them according to all their parts and dimensions, but not so as to divide them. Finally, there is one space in the whol universe and world, equal thereunto, which in divers parts receives divers Bodies. Nor when a Body is moved from place to place, does it carry its Space with it, but it passes out of one part of the Space into another, the space it self remaining wholly immovable.

Now *Franciscus Petricius* does thus conceive of Place. First, He saies it is a common Notion of all men; both that there is space, and that it is somwhat, seeing they have coyned these Terms, Dimension, Distance, Interval, Space: and that this content arose from their Sences. For al men do see that the Heaven is distant from the Earth, the East from the West, the Head from the Feet: and local motion and the migration of bodies out of one place into another, do teach the same thing. For where there was Water before, the water being Powred forth, Air enters into its place, and water again fils the place of Air.

Now he saies this Space was before all other things produced by God the great Work-master, inasmuch as all other things stood in need thereof, and without it they could not be. And whereas it is hard to know what Space is; he saies it is no wonder: for all the Qualities of Bodies whereby they incur into our senses, are later than the Bodies themselves: but Space is different from Bodies, yea and is before Bodies. For he makes Space the first of all worldly things, yea before the world it self. For if the world (saies he) should be destroied, and reduced to nothing that space in which the world is now, as in its place would remain quite empty. But if God will again make new Heavens and a new Earth, there is space beforehand, which can contain new Heavens and a new Earth. For its being now full does not belong to the Essence of Space (no more than the form belongs to the Essence of *materia prima*, though it be never without some form) but a plenitude accidental thereunto. For it happens by reason of the Bodies, which are al differrent therefrom. And he saies that Space is no otherwise a place, than as it affords a place for bodies to abide in, and of its own nature, before it is a place, it is a part of the universal space. And to that common objection, If Space be any thing, it is either a Substance or Accident, he answers: Space of it self, since it goes before the world, and is without the world, is no worldly thing, excepting that part thereof which contains the world, or which the world possesses with its Body but goes before al worldly things, whether bodily or not bodily, Substantial or not Substantial, and as all things are accidents to it, so is it to all things: and that this same space was unknown to the Authors of the Predicaments. And at last he defines Space to be an hypostatical extension, subsisting of it self, inherent in nothing. But if it must needs be of some predicament: if (saies he) that be a substance, which sustains other things, which subsists of it self, which is not inherent in any other thing, then Space is perfectly a Substance. For Space subsists of it self, it rests upon nothing, it needs nothing, to help it to be, or to sustain it, but it self sustains substances, and so enables them to be, and it supports all other things in nature. Also that it is the Original of Quantity, and that it has length, breadth, depth, and all dimensions: also that it is never moved in whol or in part, but whatsoever things are moved, are moved through this space, so that it self is wholly unmoved and unmovable. What he further writes at large see in his Book *de spacio Physico*. This one thing only I ad. The Quantity of a Body, is moved with the body it self whose Quantity it is: but as *Aristotle* himself saies, a body translated into the place of another, possesses the same place in number and nature, which that body into whose place it comes did before possess. For example sake, Water succeeds Air in the same numerical place; and so the Quantity of the Air and Water, are numerically different from the Quantity of the Space; since each remains in its own body, though it takes up and possesses another place. And seeing the Place is no part of the thing placed, nor any part (as has been shewed) of the ambient body, what other thing I pray you can we immagine, when both the Ambient Body, and the thing placed be removed, but a Space having three dimensions of Length, Breadth, Depth? And so much for this point. Let us conclude this hard discourse with an excellent saying of *Julius Cæsar Scaliger* in the 297. Exercitation. *'Tis easier for any man to oppose the Sayings and Opinions of wise men, then safely to commit his own Opinion to the judgment of others. Nor do I ever forget, but alwaies put my self in mind, to see, consider, remember, how weak the Ties of our minds are to pry into the secret Closets of Nature.*

CHAP

Chap. 8. *Concerning Time.*

A Peculiar adjunct of Essence, is that which Phylosophers cal Duration; that is, as they say, a continual tract of being, as *Scaliger* rightly has it, in his 350. *Exercitation Sect.* 7. For Duration is the measure of the being of every thing; and in every thing, these three follow one another Essence Existence, and Duration: which hold this order, that Essence is first, Existence next, and Duration last of al: Now Duration differs, as wel from the Essence as the Existence of a thing. And indeed from the Essence of a thing it differs really. For there are divers things which have the same Essence, and yet have different durations. But from the existence of a thing, Duration differs not really. For it is in a manner nothing else for a thing to dure, than to exist; and it is al one for a thing to be of a short or long existency, and for a thing to have a short or a long duration. And as the extension of Quantity is to Quantity (which nevertheless do not really differ) so is the Duration of Existency to Existency it self, yet there is some difference between them. For the Nature of existency, is only this, that a thing be out of its Causes, and actually somwhat; But Duration signifies the extention of a thing in this its being, and the continuation or abidance of the existency. Duration therefore properly belongs to existency, not to Quiddity, and it alwaies presupposes existency, without which it can neither be, nor be understood. Hence therefore Duration is not amiss defined, that it is the Extension of the Existence of a thing: or the abidance of a thing in its Essence.

How Duration differs from Essence & Existency?

Duration defined.

Now such as the Essence of things is, such is also its Measure: and as many manners as there are of a things abiding in its Essence, so many durations it has. As things therefore are threefold, so is there a threefold duration, or as some phrase it, a threefold measure of Duration; Time, Age, Eternity. For the measure of the duration of things, which are no waies infinite, and which have both a Beginning and End, is Time: The measure of the duration of things, which are partly finite, *viz.* in respect of their beginning, and partly infinite becaus they have no end, is called *Ævum*, Age or Æveternity. But Eternity is the measure of the duration, of that which is absolutely infinite, having neither Beginning nor End. But we are now to treat of Time.

A threefold Duration.

Al Men do frequently talk of Time, and are often mentioning To day, Yesterday to Morrow, and tell of daies, months and years; and in so doing they acknowledg that time is really somwhat: but what that is, very few can tel: and there have alwaies been sundry opinions about the nature of time, as may be seen in *Francisc. Piccollimineus* his *Book de Nat. com. Affect. ch.* 13. *Aristotle* reckons up three and refutes them in 4. *Phys. ch.* 10. For some would have time to be the motion of the Heavens; others the greatest of the celestial Spheres, others Motion simply considered. That wen ay therefore find out what Time is, we must know, that time may be two waies considered; First as the internal duration of a thing which has had beginning, and shal have end, and is successively continued, and to say all in a word, of a thing which is movable; Secondly for the measure of the said duration by some motion: and in this latter sense time is commonly understood by natural Phylosophers, who hold that time is not without motion, nor can be understood without motion. For then we understand Time, when we understand there has been motion, *and when we perceive no motion, we are ignorant that any time has passed*: as appears in such as sleep: For they when they are awaked, joyning the moment wherein they fel asleep with the moment of their waking, conceive no time to have passed between; which that Tale shews cited by *Aristotle* in Lib. 4. Phys. ch. 11. t. 97. Alike Story to which others relate, of three men at *Athens* who being drunk at a Festival, slept three daies together. For when one of them did awake the next night after that in which he first lay down, and saw the Stars stil shining, supposing that first night was not yet over, nor the Sun yet risen, he composed himself again to sleep, til at last awaking with his companions on the third day, he returned to the Feast, believing it was the next day following that night wherein he went drunk to bed. And a Story or Fable not unlike is related by *Pliny* in his 1 Book

of

Time is somwhat of Motion

of his *Natural History ch. 52. of Epimenides.* And dayly experience suggests the the like. Time therefore is not without motion, yea and somwhat thereof is motion. For *Time* and *Motion are perceived together.* For though we sit stil in the dark, and perceive no motion by any of our Sentes: if we conceive any in our minds, presently time presents it self therewith; and again, as often as we think of time, some motion does also therewith offer it self to our minds. Time therefore is somthing of Motion: which what it is, let us thus further search out.

Whatsoevever is moved, is moved from somwhat to somwhat, that is to say, from the term from which, to the term to which; so that between those two terms there lies a Magnitude. Now all Magnitude is continued. And therefore that motion which is made continually, through a continued magnitude, must it self be continued: and consequently Time also must be continued: for so great as is the motion, so great is the Time: and a longer motion is performed in a longer time, a shorter in a shorter. Moreover in magnitude, there is former and latter. For every magnitude is divisible into parts, which are so disposed, that some go before, others come after. For which cause, there is proportionably somwhat which comes before, and somwhat which goes after in motion: and those parts of a motion are first, by which the Movable is moved over the first parts of magnitude, and those latter, by which it is moved over the last. And for the same cause, also in time there must be a former and a latter; and so motion inasmuch as it has former and latter, agrees with time, so that by the distinction of former and latter in motion, we come to the knowledg of time. For when we consider two Instances or two extreams, wherewith motion is terminated, and understand that there is a middle space betwixt these two extreams, presently we conceive time. Contrariwise, when we conceive any thing under the notion of one Instant, and do not think of two Instances one former, the other latter: we perceive no time at all.

The Definition of Time.

From what has been said we therefore gather, that *Time is the number of Motion in respect of former and latter.* Which Definition that it may be more rightly understood and explained, these things are to be observed. In the first place, that

A twofold number.

Number is two-fold, the one *Nmubring* as two three &c. the other *Numbred* as two Stones, three Trees, four Men. The former, which is also called formal number, and wherewith we reckon, is one *Ens* or being of it self, *viz.* discreet Quantity, by cogitation abstracted from all matter, and perceptible by the mind: and it is common to all things, nor is multiplied according to the variety of things numbred. Or the word Number is taken two waies; First for Quantity discreet, or a multitude consisting of parts distinct one from another, or for any measure though continued. Now time is not a number in the first, but in the last sense; nor is time a number wherewith we count (seeing time is a continued Quantity, number a Quantity discreet) but a number counted or reckoned, *viz.* the parts of motion reckoned up, For we must not here pass over, that some distinguish betwixt a number numerable and numbred, and say that a number numerable are things, which have an aptitude to be numbred and distinguished by the understanding, although actually they are not numbred: but a number numbred are things, which are already actually numbred by somebody. And they say that time is a number numerable, or a motion, which may be distinguished, so as to have some parts going before, others coming after, although there were no man actually to number the same. From whence it appears, *that Time is a real thing.* For the aptitude to be numbred, or the numerability, does not depend upon the numberer, but is in the time and motion it self. A number numerable is again twofold: the one which Coheres to things which are really separate one from another: and such a number time is not: the other, consists of parts distinguished one from another, not really, but by our thoughts, as if a man should conceive some continued magnitude divided into certain parts; and such a number is time. For it is a flux and continual spinning out of the parts of motion, which perpetually follow one another.

A Measure twofold.

Moreover *this* also is to be observed in this place; that a Measure is twofold: one *formal* which is called *mensurata* measured, or *mensurabilis* mensurable; the other *Measuring* which is called active: which others express by saying that time is the number of motion actively or passively. Formal Measure, is that which when it

is

is in any subject, it makes it formally measurable; and thus every quantity, inherent in any Subject, makes the same to be formally measurable, and this measure is as it were an accident in that thing whose measure it is. But Measure measuring, is that which as a rule measures another thing. For this is alwaies without the thing which it numbers and measures.

Hence therfore a Question arises: *Whether Time be a measure or number with which being it self out of motion, we number moiton: or whether time be the measurable motion it self?* And although Authors say in both senses that time is a number or measure: yet primarily and principally, Time is a formal measure, and a number which is numbred. *Aristot. 1 Phys. c. 11. t. 102 and 12. t. 110.* For the nature of time does not depend thereupon, in that therewith we number other things; but herein it consists, in that it is a motion numbred according to former and latter. Moreover to be a measure (*viz.* measuring or active) is a thing respective: but time is a thing absolute. It is not therefore essential to time to be a measure measuring. For as the essence of an Ell-yard does not depend upon measuring, *viz.* that we should therewith measure Cloth or any other thing: but herein, in that it is a stick or other material of so many or so many Foot long, to which it afterward happens that we measure somwhat therewith: so the Essence of time consists herein, that it is a motion numbred, and distinguished according to former and latter, which afterward is followed by this adjunct, *viz.* to become the measure of other things. So by time, which is described by the conversion of the Heavens, we measure the motions of other things; and by the parts of time, hours, daies, months, years, we measure some whol motion or other.

Time is a Measure Measured.

Nor because time is a number; and a number does not exist without the Action of our mind: does it therefore follow, that time is only a feigned thing, and a notion of our Brains. For we must know that here are two things to be considered in time; First its *Essence*, which is a certain duration of the parts of motion; The other is its Affliction or Adjunct, which is numerability and mensurability. The former, *viz.* the absolute essence of time, does no waies depend upon our understanding, but it would remain though our understanding were gone. But mensurability does in some sort depend upon the operation of our mind. For seeing the parts of Time are either actually measured; or have an aptitude to be numbred: according to the Act and as they are actually numbred, they depend upon the operation of our mind, which being taken away, yet the mensurability would remain nevertheless. Nor when our Minds compares the parts of time past and future, joyns them, and reckons; does it fe gn any thing which is not, but finds out the parts which were before really in the motion. For as an Ell-yard, when we do not think thereof, has the Quantity of so many or so many Foot: yet the distinction and the marking them out, is the work of our mind and Art: so also Motion is of it self in nature, according to succession, without the operation of our minds; but the comparing of the parts going before and coming after, and the reckoning up the said parts, is the Action of our Mind.

Time is not a thing made.

In Time two things are considerable.

1. *Its Essence.*

2. *Affection.*

We must also in this place take notice: that although time be a reall thing, yet *it is no permanent thing*, which has its parts together actually present and permanent: but it is a *Successive* thing, which has no part actually existing, but all its parts in a continual flux and succession, so that when one is past another presently follows.

Time is no permanent thing

And we must also here enquire for better understanding of the definition: *what things motion it is which is meant in the said definition?* And we are to know, that chiefly and principally is understood the *Motion of Heaven*, which is of all others most known, most regular, uniform, and perpetual: but especially the motion of the first Movable or *Primum mobile*, of the Sun and the Moon, by whose Motions Daies, Nights, Months and Years are described. But the common People attribute no time to the motion of the rest of the Stars; because their motions are to the vulgar unknown. Howbeit Mathematicians, do not quite omit the same. And as the motion of Heaven is universally common to al Nations: even so al Nations use this Time. Howbeit, we must not say, that time is not at all in other Motions; for seeing there is former and lattter in every motion, and it may be accordingly numbred: in every motion, also there wil be time.

what that thing is whose motion is understood, in the definition of Time?

Our

Whether there be one time only or many?

Out of what hath been said another Question arises; *Whether there be one time or many.* To which that an answer may be given, we must know. First That one may here be said to be one in *Number* or in *Sort.* Secondly, That time as hath been said is *more* or *less* principal, *more* principal is of the heavens, *less* principal and secondary, of all other motions. Thirdly, That there are two things in time, as the Schoolmen speak, the one *Material* which is motion, the other *Formal* which is number. Hence we answer to the Question, That *the first and principal time, is but one in Number.* For as there is every where, and in all Nations but one motion of the Heaven: so is there but one time, depending thereupon. But if time be taken absolutely, for the number of every motion, it is not one in number: but formally indeed it is one in Sort, but materially it is many being Multiplied, according to the Multiplication of motion. For as seven trees and seven Horses, do not differ as they are seven, but as they are Horses and Trees: even so, what ever motions are together, do not differ as they are numbred according to former and latter, but as they are peculiar motions. Time therefore is formally one with all, for the Nature of present, past, and future is common to all, and those things which are distinguished according to these differences of time, they are also distinguished accord ng to time: and they which agree in any of these differences, they also agree in time although they differ otherwaies.

Whether in the definition of time Rest should be added?

And now there comes another Question; *Whether Rest should be added in the definition of time?* Because not only the motions of things, but also their rest, is numbred by time, and as wel rest as motion, is in time. But no evident reason perswades, that we should mention Quiet in the definition of time. For time is of it self the measure of motion, but of rest, by accident. For Rest because it hath not former and latter, cannot of it self be measured and numbred. For rest is measured by time, either as it is a privation of motion, for the measure of privation and habit is one and the same: and a thing is said to have rested so long a time, as it has not been moved, or as it should have been moved, if it had been moved all that while; or because the rest of one body is alwaies joyned with the motion of another, by means whereof, the rest is measured.

Whether time do really differ from motion?

And seeing time and motion do hang so one upon another, this Question must also be discussed: *Whether time do really differ from motion.* Now the sense of this Question must be first observed. For the Question is not concerning the time of the *Primum Mobile* or first moveable, compared with the motions of other Bodies. For hereof there is no Question, and all do grant, that the time of the motion of Heaven, differs really from the motion of other Bodies; seeing they are in several subjects; but the Question is, *Whether any time compared with that motion whose number and measure it is, do really differ therefrom.* And although others do think otherwise: yet theirs seems to be the truer opinion, who conceive that motion does not really differ from time. For time is nothing but motion numbred, according to priority and posteriority.

What we are to understand by priority.

Finally, This remaines to be explained in our definition: what is to be understood by fore and after or *Priority* and *Posteriority.* Touching which we are to take notice, that fore and after are not taken here absolutely, for a bare respect but as *added to the subject, and concretly for the parts of motion, including such a respect.* For priority and posteriority do in this place signifie nothing else, then the parts of motion numbred, according as they last, and one follows another.

The parts of time.

The Parts of time are *Past* and *Future:* which parts are both distinguished and coupled by the *present moment.* Yet *is the present moment no part of time*: As a point is no part of a Line. For so is *now* to time, as a point is to a Line: now that which is continued *is not made up of indivisible parts.*

Now no part of time.

Whether time generate and corrupt.

Lastly, Concerning time we must not omit to enquire *whether it be in the power of time to generate or corrupt things.* And although it is commonly said, that time does produce and perfect some things, and corrupt other some, and the Poets commonly say, Time consumes all things; Time is a devourer: Time is able to change all things, and that nothing is stonger then time, as may chiefly be seen in *Ovid* his 4. *de Tristibus, Eleg.* 6. Yet we breifly answer with *Scaliger* in his 352. *Exercitation*: That *Time as time hath no Force to effect any thing.* For seeing that it is Quantity,

tity, it acts nothing. And all those effects are to be ascribed to things, which are in or with Time. But Time it self is therefore said to corrupt or generate things, because the Application of Natural Agents for the corruption or Generation of any thing happens in time. *And so much for Time.*

Ævum.

Whereunto for Affinities sake, though they do not properly belong to this place, I think fit to ad a few things touching *Ævum* and *Eternity*. The term *Ævum*, although in that signification as it is distinguished from Eternity, and comes short thereof as having a beginning; it was not used by *Aristotle* nor the ancient Peripateticks and Platonists: Yet is it at this day very much used by School divines and other noble Phylosophers, who distinguish it both from Time and Eternity, taking it for such a duration as hath had a beginning, but shall have no end, which they attribute to Angels. Now touching this same *Evum* or *Æveternity* although there are sundry opinions of Authors: yet this shal suffice us to say in this place; that all the Nature of *Ævum* or *Æveternity*, does consist herein, that *it is the Measure of the duration of those things, which have a beginning but no end*: or as some will have it, *It is the duration of things which have no end but have had a beginning.* Now the way to measure this *Ævum* wherewith we are best acquainted, is by its coexistency, as they speak, and its relation to Time. For we say the Angels have dured 5661. years, which is the Time since the worlds Creation. Hence it is manifest, that *Ævum* differs from time and Eternity: from time in respect of the end which Time hath, but *Ævum* or *Æveternity* hath not; from Eternity, in respect of its beginning, which *Evum* hath, but Eternity hath not. Which *Leo Hebræus* expressed in his *third Dialogue of Love*: The *Æveternity* of Angels (saies he) is placed in the confines of Time and Eternity.

Eternity what it is

But Eternity, although there are other significations thereof: yet properly it signifies a *Duration which hath neither beginning nor End*, In which sense, we frequently meet with this definition thereof in *Boetius*: Eternity is a total and perfect possession of a boundless Life, all at once. For all the Essence of eternity consists in immutability or unchangeableness. For that which is *Eternal* neither begins, nor ends, nor is any way changed; but *is alwaies the same, and hath its whol Essence all at once.* Whence there results two proprieties of eternity, First, that it hath no bound, in respect of beginning or end: Secondly, that it is all at once. For though we attribute daies and years to etermity, yet we do it only for our better understandings sake. All which *Plotinus* considering, in his 3. *Ennead. Book* 9. *Ch.* 2. he saies, *Eternity is a life all together, alwaies wholly present, and not now one part and after another.* But these things belong not to this place. I conclude therefore with *Augustine*, in his 12. *B. de Civitate Dei, Ch.* 12. Nothing lasts long which hath once an end and al the bounded spaces of all Ages, if compared to boundless eternity, are not to be accounted smal, but nothing at all. Six hundred Millions of years or that sum multiplied by as many, so that there were no name for the product or total Sum, yet all compared to *Eternity* is nothing; and if the said sum be substracted from Eternity, not once or twice, but as often as any accountants are able to substract the same, yet should they never reach to the beginning of eternity, which hath no beginning.

Proprieties of Eternity.

Chap. 9. *Concerning Motion.*

WE come now to a remarkable Adjunct of Natural Bodies, *viz. Motion*, by the knowledg of which we are brought acquainted with the greatest part of the most abstruse things in Nature; and by the guidance whereof, in a manner al the knowledg of Natural things hath been found out. Now to Question whether there is any Motion, is the part only of a contentious and froward person: since it is discerned by al our sences. And therefore *Diogenes* did wel, who having heard the reasons of *Zeno*, whereby he endeavoured to prove that there was no motion, he judged them not worth the answering, but only Rose up and walked, intimating that in things subject to sence, we should believe our sences. Which *Aristotle* also approves in his 8. *Physic. Chap.* 3. *T.* 32. *to say that nothing moves, and to go about to prove it, omitting our sences, is weakness of Understanding.*

But as it is moſt known that there is motion: ſo what is the Nature thereof, is ſufficiently obſcure. And therefore, that we may the better underſtand *what motion is*, we will in the firſt place propound *Ariſtotle's* definition of motion, and diligently conſider the ſame: by which means we hope to attain to a good degree of knowledg touching the Nature of motion. Thus therefore *Ariſtotle* defines Motion in the 3. of his Phyſicks, Ch. 1. T. 16. *Motion is the Act of that thing which is in a poſſibility, in as much as it is in a poſſibility, or of that which is moveable, in as much as it is Moveable.*

Ariſtotle his definition of motion.

In this definition firſt we muſt diligently conſider the word *Entelecheia* (tranſlated Act) which as it is moſt uſual in *Ariſtotle*, and every where to be fonnd in his works; ſo is the ſignification thereof not ſo wel known, and many have taken pains to find out the true meaning thereof: ſo that it is reported of *Hermolaus Barbarus* a very learned Man, that having once attained to ſpeak with a ſpirit, he deſired nothing elſe of him, but that he would expound what the word *Entelecheia* in *Ariſtotle*, did ſignifie.

Endelecheia and Entelecheia differ

In the firſt place, we are to note that the words *Endelecheia* and *Entelecheia* are different: although ſome do confound them, wherein they are to blame. For as theſe words do herein differ, that *Endelecheia* is more ancient, being uſed by *Menander* and *Plato* in his *Timæus*, Yea, and commonly by the people of *Greece*; but *Enteletheia* is a new word, witneſs *Tully* in the 1. *of his Tuſculans Queſtions*, and by *Ariſtotle* either invented or frequently uſed; ſo they d ffer alſo in Derivation and Signification. For *Endelecheia* does ſignifie a continual and perpetual motion or agitation, ſo called from *en cai dein cai Helam to echomenon*, becauſe it is in the ſubject and draws and moves the ſame, as appears from that Greek proverb *Ranis endelechouſa coilainei petran*, the ſtil falling drop hollows the ſtone. From *Ariſtotle* in his 2. *de generat. & corrupt. Chap.* 10. and other Greek Authors.

Entelecheia what it is?

But *Entelecheia* is derived from *en* and *telos* or form *Enteles* and *Echein*, to have its end, to have perfection; and *Entelecheia* if you would render it word for word, is the having of perfection, or the poſſeſſion of perfection: and *Entelecheia* is alwaies in *Ariſtotle* oppoſed to poſſibility or aptitude, as may be ſeen in the 3. *of his Phyſick Ch.* 1. T. 2. in the 5. *of his Metaphyſicks Ch.* 2. and in his 2. *de Anima. Ch.* 1. T. 2. Out of which may be collected, what *Entelecheia* truly ſignifies. For ſeeing a thing is ſaid to be in a poſſibility to be ſomwhat, when as yet it is not that thing which poſſibly it may be: *Entelecheia* muſt ſignifie to be really and actually that which it is ſaid to be, and really to have attained to be ſuch a thing, and no longer to be in a potentiality thereunto: *and* Entelecheia *muſt be that which perfects and fils up the Poſſibility or Aptitude of a thing; and makes that the thing may now really and perfectly be ſaid to be that, which before it was ſaid to be only in way of poſſibility or Aptitude:* And to ſpeak all in ſhort *Entelecheia* is the filling up of the Potentiality or Aptitude of a thing.

This being the ſignification of this word (which though new to the dul multitude, yet was known to wiſe men to whom *Ariſtotle* wrote and not to pedants, as *Scaliger* in his 307. *Exercit. Sect.* 39. has it) it is cheifly attributed to the ſubſtantial Form, For it is the ſubſtance and perfection of a thing, and becauſe of it a thing is really that which it is ſaid to be. And indeed, as *Franc. Piccolhomineus* ſaies in his 4. *Ch. de Motu*, *Entelecheia* is applied, as well to formes free from matter as to ſuch as are joyned thereto: which opinion of his ſeems to be countenanced in the 3. *B. of Phyſicks Ch.* 7. *Text* 3. Howbeit *Zabarella* herein diſſents from him *in his Book de Mente hum. Ch.* 7. who denies ſubſtances ſevered from matter to be properly called *Entelecheias*: and he ſaies that only in one place in *Ariſtotle*, viz. 2. *Metaphyſ.* 1. 49. the ſupream or firſt intelligence is termed *Entelecheia*, and that not without Reaſon. The ſame word is alſo attributed to accidents or accidental Forms; ſeeing alſo becauſe of the things themſelves they are ſo called, and they fil that poſſibility and Aptitude which the things had to receive accidents. Yea, And as it appears out of *Ariſtotle* in his 2 *de Anima*, *Ch.* 1. T. 2. *Entelecheia* is not only attributed to forms, whether ſubſtantial or accidental, whence the operations proceed; but alſo to the operations proceeding from the forms. in a word *Entelecheia, ſignifies all that, by meanes of which every thing, is really that which it is ſaid to be.*

But

But for the word *Entelecheia*, *Aristotle* often uses the word *Energeia*, which signifies not only operation, as *Zabarel* conceives, who in his *Book de mente humana Ch.* 7. teaches that *Energeia* signifies only operation, and formes conjoyned with the matter, whose essence differs from operation as an accident, he denies to be called *Energies*; and he saies, among substantial Forms, it is only rightly attributed, to those that are free from matter. Howbeit this word is attributed as wel to Forms joyned with matter, as to those without it. For *Aristotle* in his 9. *Metaph. Ch.* 6. simply opposes to be in energy, unto being in potentiality or Aptitude, and in the same place he cals the substantial Form joyned to the matter *Energeia*: and up and down in the same Book, he cals the substantial Forms of things, *Energeias*, as may be seen, cheifly in the 8. *Chap.* which he also does in 8. *Metaph. c.* 2. And in the 4. *B. ch.* 2. *Energein* signifies not only to operate, but really to be. Also, that *Energeia* is used to *signifie the accidental Form*, appears from the 3. *of his Physicks*, *Ch.* 2. *T.* 15, and *Ch* 3. *T.* 18. but more evidently from the 20. *Metaph. Ch.* 8. where he thus writes: *Seeing every thing is divided into Act and Aptitude, I call the Act of that which was before only in power*, Energeia, *Motion.*

Energeia what it signifies & whether it differ from Entelecheia.

To these Greek words, the Latin word *Actus* does answer, which does not, in this place, signifie Action only; But that, *from which every thing is said to be what it is.* For as *Scaliger* saies in his 359. *Exercitation Sect.* 2. we must borrow ordinary words to signifie abstruse matters: which seem harsh to Novices, and ridiculous to curious Ciceronians. Now according to *Scaliger* in the same place, *An Act is that being, which wants nothing to make it be what it is, but has all its causes.*

Actus or Act what it means.

Now here in the definition of Motion *Entelecheia* is taken, neither for the perfect form, nor for the operation alone; but *for a certain imperfect Act.* For there is a twofold *Act*, one *perfect*, which when it comes, it expels al Aptitude or potentiality, and leaves none of it behind: another *imperfect*, with which there alwaies remains somwhat of possibility; which when it is taken away, the Act is also taken away; and such an Act is Motion. For seeing that is called moveable, which may be moved: motion is the fulfiling and perfecting of that possibility, in regard of which a thing is called moveable, and makes that it hath not only a possibility of being moved, but that it is now really moved, indeed and in truth. Howbeit this *Entelecheia* does not take away al possibility, but only so perfects the Body moveable, that it retaines yet the possibility of being more moved, until at length it come to the utmost term of motion, to which while it is moved, it must needs have the power of motion. For truly the thing moveable, while it is in the term from which, is not yet moved; but while it is in the term to which, it is moved no longer; but now it is moved, and ceases from motion. But then it is truly said to be moved, when it is now in the Act, in which before, when it was in the term from which, it was not, but only had a possibility of attaining the same; and when it yet tends to that further act, which in respect of the term from which, it hath not, but may attain. For if it had already the last term, it would be no longer moved thereunto. For which cause it is also said in the definition of Motion: that Motion is the *Act of that which is in possibility.* For whatsoever is moved, as may appear by the premises, is part in act and partly in possibility. In act, in respect of the Form and of that term which by motion it hath already gained, and actually possesses: in possibility, in respect of that which it hath not yet obtained, and for the sake whereof it is still moved. For examples sake: Water which is in heating, is said to be moved, that is to say altered. For it hath already some degrees of heat, and has the possibility of gaining yet more, and does likewise gain them by growing warmer: and when it has attained all the degrees, it is then termed hot water; but is not said any longer to grow hot, or to be altered and moved.

What Entelecheia signifies in the place. An act is twofold.

Motion is there fore neither a pure act, nor a pure possibility, *But a certain middle and imperfect act.* And in every motion are found these three things: *Some of the Form*, which is by motion already attained; a *power* of receiving that form more perfectly and in a greater measure; a *Flux* and Progress or Tendenay to the said Form. Finally *Aristotle* adds in the definition, *in as much as it is in possibility*, to signifie that motion is not made in respect of that Form and term, which the moveable thing hath already attained. For a thing is no longer moved for the sake of that, which it already possesses; but for the sake of that term which it has not yet attained, and which it has a power to obtain. From what hath been said,

Motion is an imperfect act.

'tis easie to gather wherein the Essence and formality of Motion does consist.

Two things in Motion. For seeing there are in every motion *two* things, one the form it self flowing; the other, the flux of the form: Motion formally, is neither simply a form, nor a form flowing, but a continual acquisition of Form, and the flux thereof, partly already acquired and partly to be acquired. For to be moved, is not to have the form; but to be moved, is to tend to the form.

To natural motion are required. Moreover, to all Physical or Natural motion, these things are required.

1 *A Mover.* I. *A Mover*: For every thing which is moved, is moved by some other thing. For it is impossible that the same thing in respect of the same form, should be in Act and in Possibility: But that which moves, or introduces any form, does actually possess the same; that which is moved has only a power to receive the form. And therefore it is not the same thing which moves and is moved. Howbeit touching this Axiome we must observe, that it is only to be understood of *material things and natural bodies compleat, and of the motion of the whol compound*; and that the intent of *Aristotle* in the 7. *Physick. cap.* 1. when he delivered this axiome was to deduce natural motion to one first Principle, and thereby to prove that there was one first mover, by which as by a first Principle, all bodies are moved: otherwise, unless this axiome be warily understood and explained, many difficulties arise, seeing not only Animals are moved by an internal force, but also the Elements by an inward principle are carried to their place, where not only the body of the Element is moved by its form to its place, but also the form it self tends to its place. See also beneath *Book* 2. *ch.* 3.

2 *A Movable.* II. *A movable* or *thing moved*, and hence every thing that naturally moves it self is divided into a part moving, and a part moved. Now that which moves must needs be with that which is moved, or that which primarily does move any thing, without the Intervention of any intermediate agent, ought to touch that thing which it moves, and to be very neer unto the same. For we cannot so much as imagine, how any thing can suffer from that, by which it is not touched, or how any thing can act upon that which it does not touch. For since operation follows the Essence of a thing: where the thing is not, there its operation cannot be. For though the first mover be absent from the thing moved in respect of its substance, yet is it joyned therwith, by the Virtue which it sends forth. And thus *the next mover and the thing moved, are alwaies together, and every action is caused by touching.* Now motion is in the thing moved. For the Act is in that thing, whose act it is. Yet is not the action of the mover different from the act of the thing moved, but there is one act of the Agent and the Patient. For it is one and the same thing which the mover produces by acting, and which is produced in the Patient by suffering. And *the Action of the mover and the passion of the moved are one only motion*, not really distinct one from another; but only *respectively*, viz. in as much as the same Act, does proceed from the mover as from its Principle, and is received by the Moved, as the Patient: which is wel expreſt by *Aristotle* in the 3. *Phys. ch.* 3. *t.* 22. *For to be the Action of this in that, and of that from this, differs respectively.* So that the same motion as it proceeds from the Agent, is an action, as it is received by the Patient, a Passion. And the heating of water by fire, is but one action: which as it proceeds from the Agent, *viz.* the fire, is called an Action, as it is received by the water, a Passion. And therefore Action and Passion are in one Subject. For seeing passion is in the Patient, and action really differs not from passion: the action must also needs be in the same Patient. Yet this must be observed that we spake here of a transient action: but not of an immanent action, which abides in the Agent.

The Action of the mover and the Passion of the moved are but one motion.

3 & 4 *Terms of motion.* III. *The Term from which.* IV. *The Term to which.* For seeing every motion is a kind of change; it must needs go from somwhat, which is called the term from which, to somwhat, which is called the term to which. And there are neither more nor less, than these two terms. For though one motion may have many terms to which: yet they are not the last & total, or they are not primarily intended and for themselves, or they are not intrinsecal. But in motion we are chiefly to regard the term to which. For that is it for the sake whereof the movable is moved, and from it the Unity, Distinction and Contrariety of Motion are chiefly taken. For seeing motion is a kind of continual progress from the term from which, to the term to which, and the term from which is rejected, and the term to which acquired: justly

ly therefore the motion receives its denomination and distinction from the term to which.

V. *Time*: For no motion is performed in an Instant, but *Successively and in Time*. For since motion is the Act of a Being in possibility, and has no abiding Essence: of necessity the thing moved, must be partly in act, and partly in possibility: and therefore motion must be successive. For if it were all together, it were all in Act, and the thing could no longer be said to be in motion, but already moved. 5 *Time.*

VI. *Continuity*, or Unity of Motion, in respect of time, and the term to which. For the Continuity and Succession of the Motion depends chiefly, upon the Term to which the motion is made; and the motion is said to be performed successively, because the Term to which the motion tends, is successively gained. But that a motion may be one in number, *three* things are requisite: one movable, one term to which; and one continued time. To which a fourth may be added, the Term from which. For one motion cannot proceed from divers Terms. 6 *Continuity*

What is the Nature of Motion has been explained hitherto, it remains that we now shew you what are the Sorts of Motions. Where in the first place you are to take notice, that there is a difference betwixt *mutation* and *motion*. *Metabole* or Mutation is of larger extent, and signifies every variation of a thing, whether the terms in respect of which the thing is varied, be positive and contrary, or contradictary: but *Kinesis* or Motion properly so called, is not of so large an extent, but is conversant betwixt terms (upon which, especially the term from which its nature chiefly depends) which are contrary, or if mediate, yet having the nature of contraries. *Motion & Mutation differ.*

Motion therefore *properly so called is conversant betwixt contraries.* Now we term such things in this place contraries, not only which do most of all differ under the same kind: but whatsoever positive terms, by the coming of one of which another is changed, whether it be in respect of contrary qualities, or according to intention, or according to extension. Whatsoever therefore ought to be reckoned for a term of motion, must have these two conditions. First that it have a contrary in such a manner as has been said; so that the motion must pass from one contrary as the Term *a quo* from which, unto the other contrary as the term *ad quem*, to which. Moreover, that must of necessity be attained, which terminates the motion of it self, and not without the change of the Subject, which is performed by real action and passion. *Motion is made betwixt contraries.*

From which may easily be gathered, that true motion is *only in three Predicaments*, viz. *Quantity*, *Quality*, and *Ubi* or Place; or that in respect of that thing to which the motion tends, it may be reduced to these three Predicaments. For both the forms of these Predicaments have contrariety, and positive oppolite terms; nor can their change happen without the change of the Subject. *Motions are only in Quantity, Quality & Place.*

But Generation and Corruption which are changes in the substance of a thing, are not properly Motions. For that Contrariety necessary to motion, is not found in substances. Moreover, since every thing which is moved is an actual Being; but that which is generated is no actual Being (for if it were already, there were no need that it should be generated) therefore *Generation cannot be a Motion.* Lastly, *Every motion is continued and performed in time*: but generation is not performed in time, but in a moment, and therefore also it cannot be a Motion. For substantial forms being indivisible and not capable of more or less, cannot be successively acquired and by piecemeal. *Generation and Corruption are not properly Motion.*

Howbeit we must here observe, that Generation and corruption are taken *two waies*, either only for the acquisition or loss of a substantial form, without precedent alteration: or for the introduction of a form, with alteration which went before the same. Generation and Corruption taken in the former Sense, are no motions, but are performed in an Instant: but in the latter sense they may be allowed for Motions. *A two fold Acception of Generation & Corruption.*

Moreover, this must not be omitted neither. That *Succession in motion is considered two waies*: Primarily and chiefly as was said before, *in respect of the form*, which seeing it may be intended and remitted, and has certain degrees, in respect of which it is capable of more and less, it therefore successively acquires those degrees, *viz.*, one before, another after. But since the substantial form has no such degrees, it cannot

cannot be intended, nor remitted, nor is it successively introduced, but in an instant and all at once. Afterward there is said to be a succession *in respect of the Subject*, which is movable: which succession others seem to call extension. For since a thing movable is divisible, and has some parts formore others hinder: and the mover acts first upon the formore parts and which are neerest it self, and afterwards upon the hinder and more remote: also in this manner we may grant that Generation is made successivly. But both these successions are considered, in motion properly so called: but the former holds more of the nature thereof: which being absent from Generation it cannot be called motion.

Moreover, it is evident, that there is no motion in *Relation*, *Action*, *Passion*, *When*, and *Habit*, the Predicaments so called. For those mutations which are made in them, do either not happen with the change of the subject, or not of themselves primarily, but consequently and by accident.

The sorts of Motion. *Motion* therefore *properly is only made out of one subject into another*: and there are three sorts thereof. In Quantity there is Augmentation and Diminution. For these two mutations have no common name. In Quality, there is Alteration. In Place, there is local motion from place to place.

Rest what it is. To Motion *Rest* is opposed, which is the *Privation of Motion in that thing, which is naturally apt to be moved*; and in as much as motion is made to attain rest, it may also be said to be the end and perfection of motion. So a body, when it has attained its natural magnitude, ceases growing.

Rest twofold. *Rest* is either *natural*, whose principle is internal, and to which the *movable* is naturally enclined: So the Earth is naturally moved to the Centre, and rests there. Or *Violent*, whose Principle is external, when a body is kept by force in a place not natural thereunto; as when a stone or clod of Earth, is hung up in the Air.

THE SECOND BOOK

Chap. 1. *Of the World.*

HItherto we have treated of a natural Body, as it is a General term, comprehending sundry sorts, and we have spoke of the common Principles and common adjuncts of a natural Body in general, without any consideration of the sorts: we are now to come to the *several sorts of natural Bodies*. And because the whol mass and heap of all Bodies natural, does make one total sum, which is called *the World*; before we treat of any sort of natural bodies, or of any part of the world, we must first speak of the whol, and explain what the world is, and what proprieties and adjuncts it has.

The sundry significations of the word Mundus That which is by the Greeks termed *Cosmos*, because of its absolute and perfect Elegancy and Ornament the Latins call *Mundus* for the same cause: which word because it signifies a thing which is absolute, perfect and comprehending in it many things orderly ranked, many things are so termed. *Marsilius Ficinus* on the 3. *Book of Plotin. Tnead* 1. makes two worlds, one intelligible, being the divine mind, the Pattern and Idea of this sensible world: the other sensible, *viz.* this which we behold, being the Image of the divine Pattern. Others do again divide these two worlds, and make more worlds. The first is the Archetype or Intelligible world, which is the divine mind or God himself, who contains in him the patterns and Ideas of all things: the second is the angelical world, made up of the multitudes of Angels rank'd in their Hierarchies: the third is the Elementary, which is made up of

of Heaven and the Elements: the fourth is the great world, which contains al created things, both corporeal and incorporeal: the fift, is the little world or *Microcosme*, which is Man.

We are in this place chiefly to treat of that world which consists of Heaven and Earth and the Bodies therein contained, and by another name is called *to pan*, the Universe becauſe it comprehends al natural bodies, & to which the term *Mundus* or World does chiefly belong and which in regard of its order was given it by *Pythagoras* as *Plutarch* saies in the 2. of his *de placit. Phyloſop. ch* 7. though we may doubt hereof, becauſe the word *Coſmos* is read up and down in the writings of *Hermes Triſmegiſtus*. For this universe is truly *Coſmos* or *Mundus*, that is to say adorned, orderly marſhalled, and beautiful. And therefore *Ocellus* inſcribed his Book of natural things *peri tou pantos*, *de univerſo*, of the Universe, and touching theſe names he thus writes. *I cal this whol world by the name of univerſe: For becauſe it is diſtinguiſhed and adorned with all things that are, therefore it has gained this name* Coſmos *and* Pan, *the world and Univerſe.*

And as there are ſundry ſignifications of the term world, ſo there are ſundry definitions or deſcriptions thereof, which *Franc. Piccollo nineus* has collected in his Book *de Mundo* ch. 2. But thoſe are of all other moſt pertinent and moſt fit for this place, which the Author of the *Book de Mundo* has in his 2. Chap. (for whether it be *Ariſtotle's* or *Theophraſtus's*, or of ſome other Author is a queſtion, of which ſee *Ludovicus Vives* upon *Auſtin de Civitate Dei Lib.* 4. *Chap.* 2. *Collegium Conimbricenſe* in the proeme to *Ariſtotles* Phyſicks queſt. 5. art. 4.) the firſt is this, *The world is a Fabrick framed of the Heaven and Earth and the Natures in them contained.* The ſecond is this, *The world is the Order and Diſpoſure of all things, which is preſerved by and through God*: which may thus I conceive be fitly joyned both in one. *The world is that ſame orderly Diſpoſure of all natural Bodies, proceeding from God and by him preſerved.*

The *Matter* therefore of the *world* are all natural Bodies, not only ſimple but alſo mixt; not only liveleſs, but alſo living: yea and univerſally, a natural and ſenſible Body, as *Ariſtotle* ſaies in his 7. *de Celo*, ch. 9. t. 98. And the world is compounded of the Heaven, the four Elements, mixt bodies, inanimate and animate, mettals, things dug out of the ground, Plants, and Animals or living Creatures. *The worlds matter.*

But what is the Form of the world is not ſo evident, and there are ſundry opinions thereabouts. For ſome ſay God is the Form of the world; others a ſoul common to the whol Univerſe; others, the Heaven; others, its Figure; others, Order. But among theſe opinions, two have at this time the preheminence: the one is that which attributes a certain ſoul to the world for its Form: the other is that which makes order to be the form of the world. That the world has a ſoul is an old opinion, approved by many moſt renowned men. It is countenanced by *Hermes Triſmegiſtus*, *Zoroaſter, and Orpheus*. So in his Book called *Nous pros Erme*, *All things* (ſaies he) *are ful of ſoul.* And in his Book *de Intellectione & ſenſu*, he attributes a proper Sence and Intelligence unto the world. *Pythagoras* held the ſame, with *Plato* and his Followers, who oft times cal the world a living Creature, and aſſign it a common ſoul, which every where through Land and Water, contains in it ſelf ſpiritual and quickening ſeeds; and of it ſelf ingenders, wherever corporeal ſeeds are wanting; and alſo cheriſhes the ſeeds left by Animals, and of a putrified Grape-kernel engenders a various, orderly and precious Vine; which wherever there wants a generator, and accidental qualities ſeem only the Cauſe of Generation, ſupplies the place of a generating Subſtance; as *Marſilius Ficinus* ſhews at large, *in his* 4. *Book of Platonick Theologue Ch.* 7. *Touching the form of the world ſundry Opinions.*

But the Peripetaticks like not of this Opinion For ſeeing no evident reaſon perſwades the ſame, nor is there any neceſſity that it ſhould be ſo; they neither attribute to the world any informing Subſtantial form, nor one common ſoul, nor do they think it fit to multiply things without great occaſion. For no Action does plainly appear in the whol world, as proceeding from any peculiar ſoul common to the whol world: but all operations do proceed from peculiar and diſtinct forms. And therefore ſince all parts of the world have their peculiar forms, there needs no common form to knit them together; ſeeing without it, the ſeveral forms can perform their own operations. Moreover, if there were one form informing the world, the other forms, muſt either be parts thereof, or be informed thereby; both

both which are absurd. They cannot be parts; for all formes are not univocal, and differ more then in kind, nor can they make up one whol: And one form in number, cannot constitute distinct things, such as Natural things are. For since the form gives unity as wel as being: all Natural things should be termed one rather then many. And that the other formes should be informed by this, is also many waies absurd. Nor is there any reason to beleeve that this form of the world, comes upon the other forms, just as the form of a living Creature comes upon the form of a mixt Body. For if this were so, it should be more excellent and more perfect then the rest of the forms: which the Platonists nevertheless, will not grant. For the Soul of the world does not include more and more excellent faculties, then the forms and Souls of all Natural Bodies.

And therefore the Peripateticks deny that the world is one, by the unity of a Form informing; and they attribute thereunto only an unity of order of those things, which proceeding from one principle, do tend unto the same as their end, agreeing one with another and with it; because all things come from one and tend to one, as *J. C. Scaliger* saies in his 6. *Exercitation. S.* 2. The Form therefore of the world is *the order or orderly disposure of Natural Bodies* Howbeit, we are here to observe, as Number is twofold, the one numbering, or wherewith we number, the other numbered, which is nothing but the things themselvs which reckoned: so there is a *twofold order*, an *order ordering*, which is an accident, and the mutual respect of the parts one to another, or as *Augustin* defines it in his *de Civit. Dei B.* 19. *Ch.* 13. a Disposure which among things like and unlike gives every one its place: and an order *ordered*, which is nothing but the things themselves aptly disposed, and such is the world. For natural Bodies, as they are aptly disposed, and participate of the condition of one first principle, and mutually accomplish and cherish one another, do make one orderly System, which is called the world.

The Form of the world.

The Efficient cause of the world.

As to the efficient Cause of the world, though the Epicureans were so mad as to think and say that this beautiful Theatre of the world was made by a blind and fortunate concourse of Atomes: yet all sound Phylosophers agree in this, that this world depends upon the *most good and great God*, as the only first principle of all principles. For as *Austin* in his *de Civit Dei B.* 11. *ch.* 4. saies, The world it self, by its most orderly mutability and mobility, and the most beautiful Feature of all visible things, does after a sort silently proclaim both that it was made, and by none but God, nor could be made by any but him, who is unutterably and invisibly great, and unspeakably and invisibly fair. And *Scaliger* in his 3. *Exercitation*, shews that *Simplicious*, *Philoponus*, *Ammonius*, *Avenroes*, and many other renowned Men, neither fewer in number nor of less Authority, then those of the contrary foolish opinion, did hold that the world depended upon God, as its Efficient Cause: and at last, thus concludes. For if by his Providence all things are governed (which no man in his wits can deny) it necessarily follows, that he was the maker of al. For if he made not the world: then he received it made by another, either as borrowed, or by force, or by sale, or as a pawn, or hired, or by lawful succession, or seazing upon it when empty, or by command, as a Minister, Servant and Mercenary from his Lord. All which are meer trifling and Impious Conceits.

The End of the world.

As for what concernes the end of the World: The *End* moves the Agent to act. But there was nothing before the world saving God alone. Nothing therefore moved God to create the world, but he himself moved himself. and therefore he created it, that he might communicate his infinite goodness. Which *Augustine* has neatly expressed in these words, *de Civit. Dei Book* 11. *Ch.* 21. *Three things we ought cheifly to enquire concerning the Creature, who made it, by what he made it, and wherefore he made it. God said* (quoth he) *let there be light, and there was light, and God saw the Light that it was good. If therefore we ask who made it? it was God. If wherefore he made it? because it is good. There is no more excellent Author then God, no more efficacious Art, then the word of God, no better Cause, then that what is good might be made by the good God.* Nor does *Plato* render any other cause, why God made the world, but because he is good. For it is the property of goodness to communicate it self. And this is the end of creating the world.

But what the *End* is of the world already constituted and existing, is elegantly taught

taught us by *Hermes Trismegistus*, in his Book *de Pietate & Philosophia*. *First there was God, then the World, then Mankind; the world for Mankind and Mankind for God.* For since every end is good, and the perfection of that thing whose end it is; and God is the ultimate and most perfect of all things: God must needs be the end of all things, and all things are for that one, which is for none but himself: and al things stand in need of God, Both to be and to be well: Man therefore was made for God, and the world for Man. But how all sorts of things are made for Man, is not so plain. For *Scaliger* cals them the Enemies of Truth, who will have all things to be made for the use of Man. For what profit hath Man from Fleas and Wiglice? 'Tis truly ridiculous to say, that Fleas are made to suck out the unprofitable blood, and Wiglice to awake us in the night, that we may fal to our prayers. Nor does *Scaliger* allow that some sorts of things were made only for varieties sake, and to stir us up to admiration: but he determines that God made all things for some certain end. For variety and bare ornament, is not the end, nor the Perfection of the Universe, but a way only to that perfection. For from sundry sorts of things orderly disposed, the perfection of the Universe does arise. *Scaliger* therefore himself thus resolves the matter: that Man is a little world, and as it were the Rule and measure of other living Creatures; yea and the Prince of al. But he could not be Prince unless he were such as he is, *viz.* In the middle: nor could he be in the middle, unless betwixt extreams. Therefore the extreams were made that he might be in the middest: and if any of the extreams, or those things seated betwixt the middle and the extreams were wanting, there would be a vacuity amongst the forms. Which is much more absurd, then that there should be a *Vacuum* without a Body. For seeing the most good God is ful of himself, and the world as the *Platonists* say, is Gods Statue or Standing Image: it must also be ful, and have no defect either in sorts, or Quantity. And therefore if even the smallest thing were wanting in the world, the Universe would be no longer the Universe, and the world would cease to be the world, that is to say, beautiful, orderly ranckt, and perfect.

God is the end of all things.

And thus far we have known the world by its Causes; it remaines that we take a view of the cheif adjuncts therof, and discuss the controversies raised touching them. Now in the first place comes Eternity; and the question is, *Whether this world be Eeternal or not?* This question is much canvased by the disputes of many Men, and the opinions of Phylosophers concerning the same have been various; some affirming the world had a beginning and shall have an end; others that it had a beginning but shal never have an end; and others again that it never had beginning nor shal ever have end. That we may therefore disintangle our selves from so great a variety of opinions, we must first observe this: that the chief question in this place is not: whether God made the world. For though the madness of some hath been so great, that they durst say that this world was made by Chance; yet al sound Phylosophers, do agree that God is the author of the world: and therefore the Author of the Book *de Mundo*, *Chap.* 6. saies Elegantly and Piously: *It is an ancient saying spred amongst all Men from their Ancestors, that all things were made both of God and by God; nor can any Natural thing be sufficiently furnished to persist in safety, if it be left to its own saveguard, without the tuition of God.* And that *Aristotle* himself knew the most good and great God to be the maker of the world, and that he expressed as much in words, is the judgment of most worthy Phylosophers. Verily if the world were not made by God, it must be made by it self: which is absurd. For a finite thing cannot be the first being; and every finite thing depends upon some other: nor are there many prime, infinite, eternal beings.

Whether the world be eternal.

The World was not made by chance.

Here therefore the question is; *Whether the world be from eternal, or were created in the beginning of Time?* The most renowned Ancient Phylosophers have held, that the world had a beginning. But *Aristotle* held that this world hath been from all eternity, as himself witnesses, in his 1. *de Cælo ch.* 10. *t.* 102. But let not us care what this or that Phylosopher hath thought, seeing our Religion does teach us, that this world was made in the beginning by the most great and good God. For whom may we better beleeve when the world was made, then God himself the Author thereof.

The World is not eternal.

But whether or no, setting aside divine revelation, it may be firmly proved by natural Reasons, that the world is not eternal, many do doubt. *Iul. Cæs. Scaliger*,

in his 61. *Exercitation* S. 6. saies that Religion only does perswade him, that the world had a beginning and shal at last be consumed by fire. Yet he concludes in his 77. *Exercitation*, S. 5. that because God is the efficient cause of the world, it must needs have had a Beginning and not be eternal. For whatsoever is made, is after its efficient cause, and nothing that is made is of equal durance with its maker, for so it should not be made. This Argument others also use, and say that for a thing to be made and to be eternal implies a contradiction. For that which was made, somtimes was not. And they say that Eternity is the duration of God alone, nor can any creature be Coeternal with its Creator.

Nor are those Arguments which *Aristotle* and his followers bring to prove the eternity of the world, such as mans wit cannot answer and refute. And I conceive it is well said, that no reason brought against our Faith is true, or can be: because truth is not contrary to truth. For though things of Faith are above the order of Nature, yet they are not contrary thereunto. For even here, these who contend for the eternity of the world, do cheifly build upon two fals foundations: one, that Creation is impossible, and that even the first cause cannot produce any thing out of nothing: the other, that God acts by the necessity of his Nature.

Creation is possible according to Phylosophy,

Now that Creation is not impossible and that the first Cause can produce somwhat out of nothing, may be evinced even by the light of Nature. For such as is the being of a thing, such is its operation: but the immortal God, since in respect of his essence he depends upon none, and needs no outward thing, neither does he need any external thing to be presupposed in his acting. Moreover God is the cause of all things, and nothing except God hath its being of it self, but all things depend on God. And in very deed, they who deny creation, and say it is impossible God should make any thing of nothing, and yet grant that God is the Efficient cause of the world (for they must needs grant that) do contradict themselves. For if God be the efficient cause of the world: doubtless, he made it of nothing. For besides God and the world, there is nothing out of which he should produce it. Others bring more reasons to prove the same. And in truth, they who deny that God could produce somthing out of nothing. they deny God to be God, that is to say, that his power and perfection is infinite.

God made the world freely.

And that God acts freely and not compelled by his Nature, and that he most freely produced this world, is not contrary to humane reason. For since God is a most perfect being, depending upon none, standing in need of none, self sufficient, *Autexousios*, *Autagathos*, and (which word was elegantly invented by *Scaliger Exercit.* 365. S. 2. *Autautos*, self, of himself: the wil of God cannot necessarily desire any Creature, nor can he necessarily produce any, nor can his power be compelled by any thing: but himself most freely wils, what by his wisdom he knows to be best: and he could, if he pleased, have made this world much sooner or later, or not at all. Yet he does alwaies, that which is best. Nor, because he made the world in the beginning, was his will therefore changed. For from eternity, it was his pleasure to produce the world, then when he produced the same. Nor must we think, as *Austin* speaks in his *De Civitate Dei B.* 11. *Ch.* 5. That any thing hapned accidentally to God, in that he made the world rather then, then in former times; since the former times had passed equally through infinite spaces, neither had there been any difference, why one time should be chosen rather then another. And as he saies, *in the said* 11. *Book*, *Ch.* 12. where he handles this argument excellently; that which we now enquire after five thousand and od years, posterity may ask with the same Curiosity six hundred thousand years hence, if this mortal condition of men born and dying shal continue so long, and they retain their childish infirmity. Those who were before us in the infancy of the world might move the same Qnestion. Yea and the first man himself, the day after, or the same day he was created, might enquire why he was made no sooner. For indeed, as he saies in the same place, all the bounded spaces of Ages, if compared to boundless Eternity, are nothing.

The world shal have an end.

As it appears from Scriptures, that the world had a beginnirg: so they alone perswade us that this World shal have an End; nor is any Phylosophical reason strong enough to prove the same. For though it be true which *Scaliger* saies in his 61. *Exercitation*, S. 5. and *Exercit.* 307. S. 20. that all things because they have not the cause

cause of their being from themselves, but depend upon another, are of themselves mutable, and corruptible; but are not corrupted, because God wil not have it so: yet true it is, that the world left to it self, with that common and ordinary concourse of God which now it has, may for ever endure, nor does it of its own accord tend to corruption: but it shall end by the free command of God, *viz.* when he shal withdraw from it his ordinary assistance, and change it into a better condition. And so much for that Question whether the world be eternal.

Whether there is but one world.

Nor is it much less controverted: *Whether this world be one.* For here Phylosophers are at great variance, as may be seen in *Mirandula* his *Exam. vanit. doct. gent. Lib.* 7. *Ch.* 20. For some have held the world to be but one, others that there are many worlds, and they either like or unlike one another. For some were of the opinion, that there were other worlds besides this, in some of which there is neither Sun nor Moon; in others, that there is Sun and Moon greater then those in this world; and in some many Suns; also that there are some Worlds void of al Plants, Animals, and Moisture: and *Metrodorus* did say, that it is as absurd that there should be but one world, as that in a vast field there should grow only one Ear of Corn.

In this variety of opinions, we beleeve there is but one world: but we hold setting aside what may be urged from our religion, that there is no Phylosophical reason strong enough to prove the same. For sure enough God can and could have made more worlds: But whether or no he will make more: none can tel but himself, seeing neither sense nor reason can inform us. For as for the reasons every where alleadged by *Aristotle* and others for the unity of the world; they are not such as do certainly prove the same. Which *Plutarch*, besides others, does shew in *his Book of the Ceasing of Oracles*, and Mirandula *in Exam. Vanit. Doct. Gent. L.* 6. *Ch.* 9. who at last thus concludes: truly, as it seems to me, if those other worlds pleaded for, be of several sorts, *Aristotles* reasons will be invalid: because the sort of Earth and water and other parts and their Nature would be different. For so the parts being of one and the same Nature would hang together and would not go out of their world; all heavy bodies would seek their own Centre, and that lighter would fly upwards, and the same may be judged of the rest, proportionably.

Howbeit this one world does sufficiently demonstrate the goodness of God, because he made it of his own accord, not being obliged so to do; also it shews his great power, because he could make it of nothing; and exceeding great it shewes his Wisdom, because he hath made al things so admirably and with such rare skill.

The World is perfect.

And although we beleeve this world to be one; yet we hold the same to be perfect, with such a kind of perfection as a Creature is capable of. For it was made by a perfect Artist according to a perfect Pattern: nor is there any thing wanting, in the absolute perfection of the things whereof it is made up, nor in their Variety. For it containes all degrees of beings. Nor in order: for in so great a diversity of things, there appears a rare order, and all things are fitly disposed in their places: all which are enclosed with the Heaven, which because it is round, the Figure or accidental form of the world, therefrom resulting, is round also. *And so much of the world in General.*

The figure of the world is spherical.

Chap. 2. *Of the Heaven, and the Stars.*

NOw the world is divided into *two* Regions, the *Etherial and Sublumary*: and being to treat of the Ethereal or Celestial in the first place, those most Famous Questions present themselves, agitated by the disputes of most Famous Phylosophers, now for many Ages: *Whether there is matter in Heaven*: and if there be, *Whether it is of the same Nature with that which is here below.* And although as to the former question, there are scruples good store on al sides: yet that opinion seemes to me more probable which attributes matter to the Heaven and I conceive it was well said of *Scaliger* in his 359. *Exercitation*, Sect. 11. *to make a Body without matter*, is all one as to make a dream without sleep: or as he hath it in his 1 *de plan-*

Whether the Heaven have matter in it.

tis Bread without meal. For where ever there is quantity, Figure and Local motion: there must needs be matter. For Quantity immediately follows the Nature of matter, and cannot be in any thing without it, and all forms and accidents have no quantity of themselves, but are said to have quantity, because of the Quantity of the matter wherein they are. Wherefore since we see, that the Heaven hath quantity, is of a certain Figure, and a determinate magnitude, and locally moved: we must needs confess that it hath matter in it.

Whether the matter of the Heavens be the same with that of inferiour Bodies.

But what kind of matter this is, whether such as this of ours, or some peculiar: is so obscure a Question, that resolve which way you will, you may easily find arguments to maintain your Assertion. We deny that the Heaven consists of one or more of these Elements of ours, which was the opinion of very many an cient Philosophers: yet I conceive we should not assign it any other matter, then this first matter of ours. For there is no need to invent a new one, nor any necessity to introduce a new being, into the Catalogue of Nature: since what ever is attributed to the Heaven in respect of its matter, may rightly be attributed to this matter of ours. *Scaliger* therefore in his *Exercitation*, 61. does well conclude this Question: One matter differs not from another, save by the Form entring thereinto, whereby it becomes this or that. For matter as matter, includes no act in it self, and has nothing determinate, but receives all determination from the Form. Whereunto this may be added, that in Heaven there is Quantity, and some other Qualities, which are common to it and these inferior Bodies, and proceed from the first matter. Which things being so the opinion of *Avenroes* cannot be admitted, who invented a new simple Body not compounded of Matter and Form, and held that Heaven was a Body, that was neither pure matter, nor pure Form, nor any thing of them compounded, but a certain middle thing betwixt these, *viz*, A certain form consisting of it self, furnished with dimensions and apt for Local motion. For these things seem to be invented without cause, yea and hard to conceive, That there should be a thing (to use *Scaligers* words *Exerc.* 61. *S.* 1.) in Nature subsisting of it self, which is neither God, nor an Act, nor a power; neither informing nor informed; neither matter nor immaterial; neither a Body nor incorporeal; without the Predicaments, and yet having Predicamental Quantity and Qualities. Which what for a thing it can be, let himself consider. And if it could be proved, that there is a simple Body not compounded of matter and Form: verily a great foundation of peripatetical Phylosophy will fall to the ground. And if there were such simplicity in the Heaven: there can be perhaps no cause assigned, why it might not also be admitted in some sublunary Bodies.

Nor if we should attribute to Heaven this first matter of ours, need we to fear that the Heaven should fal and at one time or another of its own Nature come to destruction. For according to *Zabarella* himself *Lib. de Ortu & Interitu c.* 11. who nevertheless in this point takes part with *Averroes*, the first matter, seeing it is a being meerly potential, and acts nothing, is no adequate Cause of Generation and corruption of things: and every action is to be ascribed to the Agent; and to matter, passion only belongs. Nor is matter the subject of Corruption, save when it is with Natural Forms corruptible, from which the accidents flow, which have contrarily, or contraries also under contrary differences. Therefore we must not deny the Heavens to have matter, though they be not generated nor corrupted. For there are two offices of matter. Universally and primarily it is given to all things, to sustain Quantity, and to receive motion, and the actions of Agents. For it is the first subject of Quantity, and is meerly passive, acts nothing, but only suffers: and all things naturally suffer, because they have matter. Moreover Matter is given to sublunary things, because of Generation, to which it concurs as a secondary cause, *viz*. In as much as it is apt to receive the Action of the Generator. The cause therefore why there is no Generation nor Corruption in the Heavens is, because there is nothing contrary to Heaven, by which it may be corrupted, and because it has no Particular aptitude to receive other forms, which is only opposed to act, and is really the same thing with privation. For in Heaven there is no Privation of corruptiple Forms; because the Heaven hath no immediate aptitude to receive sublunary Forms. But the Form of Heaven does so dispose and bind its matter to it self, that it has no Particular aptitude to receive other Forms, but only that same universal one, which is an aptitude to receive all Forms indifferently; in respect of which nevertheless unless a Particular aptitude be added, and a contrary agent

agent be at hand, no Generation is made. Yea and (which I would have those to consider, who think the Heaven must perish, if it have matter) the Earth which is in the Centre of the world is safe from all Corruption nor is corrupted, because no contrary Agent pierces so far, by which it might be corrupted. We conclude therefore; that *The matter of Heaven has no particular and immediate aptitude to receive corruptible forms; and that it has only an appetite of perfection, but not of Mutation*, as *Scaliger* saies. For the Matter because it cannot subsist of it self, desires to be perfected by the form, whatever form it be, whether of a Man or of a Beetle, nor of its own accord does it lay down one form and take up another; but the whol vicissitude of Generation and Corruption, depends upon the Contrariety of the forms and the qualities issuing out of them, as on its principal Cause: which seeing the Heaven has not, we need not to fear, that it shal come to decay, only because of its matter. Of which see more in *Scaligers Exercit.* 17. and 61.

Moreover that is also no Inconvenience *that there should be one matter of Celestial and Sublunary things*. For the difference and excellency of things proceeds not from the matter, but from the form; and the same first matter which bears the form of a Mushrome or Flea, is also the subject of our understanding, which is verily a divine Substance, and more noble than Heaven it self.

What is the Form of Heaven

Nor is it a less Controversie, *What that form of Heaven is*. *Averroes* and they which follow him do not allow the Heaven an informing Form, but say that it is a simple body, without composition of matter and form. But this opinion has been already rejected. But we do more rightly to attribute unto Heaven an *informing Form* also, since as we have shewed it consists of matter. For matter cannot subsist of it self, nor perform those most noble actions which proceed from Heaven, besides its motion; since it is purely passive, and no action belongs thereunto. Yea and matter of it self, cannot be moved: for *every thing which is moved is an actual Being*.

Whether the Heaven has a Soul.

But *whether it be formally a soul or not*, needs inquisition. It is indeed an old opinion of the Pythagoricks and Platonicks, that the Heaven has a soul: howbeit the contrary opinion is truer, which holds that the Heaven has no soul. For there appears no actions of any kind of living Creature therein, which can proceed from a soul; nor has it any of those Organs, which are necessary to perform the actions of a living Creature. The Heaven is not nourished: because in Heaven nothing is corrupted or dissolved, whcih needs to be restored by nourishment: nor does it feel because it has no organs of feeling, nor of other sences, nor is there any end for which the Heaven should have sences: Much less can we allow an intelligent soul to the Heaven to inform the same, lest we fal into that Error which many have condemned in *Origen*, who taught the Stars had souls and were capable of Virtues and Vices. It is sufficient therefore to attribute to the Heaven a form which is no soul; but yet more noble than the forms of the Elements, by means of which, it is that which it is, has a certain figure, and a certain power by means of its Light and Influences of acting upon these lower bodies, and also motion. And this is the matter and form of Heaven by means of which it is also rightly termed a natural Body. For if it were destitute of these, a just cause could hardly be found, why it should be called a natural Body. And this Body consisting of matter and form is termed Æthereal.

Some parts of the Heaven perspicuous, some not, Whether the Heaven is one continued Body?

Moreover the Parts of the Heaven are *twofold*, some *quite perspicuous*, which are the Orbs, and are sometimes in a special manner cal'd Heaven, others *are not to be penetrated by our sight, and shining*, called Stars. Touching the Orbs certain weighty questions are moved, and in the first place we are to enquire: *Whether the Heavens be one continued body, or distinguished into divers Orbs or contiguous Spheres*. Now the ancients have endeavored to prove that there are many Heavens, by reason of the diversity of motions, which cannot be in a simple body: seeing every simple body, is moved with one simple motion naturally, as *Aristotle* tels us 1. *de Celo ch.* 2. *t.* 7. For when the ancient Astronomers and natural Philosophers, began to observe the motions of the Sun and Moon and other Stars; they observed that all the Stars did not observe the same swiftness and distance, in their motion, but that some were moved more swiftly, others more slowly, some never joyned but alwaies keeping the same distance one from another, and others again coming neerer one to another, even to a conjunction; that the Sun went alwaies in the middle of the Heaven,

Heaven, and that the other Planets declined some whiles to the North other whiles to the South. From which variety of motions they gathered; that the Heaven is not one continued Body, but is compounded of divers contiguous Orbs.

But most of the latter Writers deny, that the various motions of the Stars do rightly prove a plurality of heavenly Orbs; and they aver that this variety of motions does not proceed from the number of the Orbs, but that it belongs primarily to the Stars themselves. And in very deed it is more likely, *that the Stars are moved of themselves with their own proper motions*: and that the Heaven is a body, not hard, nor distinguished into real Orbs, wherein they stick fast and are moved by their motion, *but a body fluid like the Air, of a substance most thin and delicate wherein the Stars perform their motions.* For not to speak now of refractions, of which if the Heaven were solid, there should be two. one by reason of the vapors ascending from the Earth, another by reason of the solid body of the Heaven: whereas nevertheless those skil'd in Opticks and Astonomy, have observed one only refraction which is sensible and worthy of note: the motions of the Comets, do evidently demonstrate that the Heaven is not solid. For since it is now out of Controversie (unless any wil call in question the most certain demonstrations of Astronomers) that Comets or unusual Stars (for we shal not now contend about the name) have been seen in the Region of Heaven above the Moon, and have observed peculiar motions, not like the motion of any other Star fixed or planetary; this could not be, without the penetration of Bodies if the Heaven did consist of solid Orbs: For if the body of the Comet were fixed in the orb of any fixed or planetary Star, it would alwaies keep the same distance, from the said Star or Planet. Which since it does not, a peculiar Orb should be attributed to every Comet, to carry the same about: Which cannot be; since the whol Cystern of Heaven according to the ancient Doctrine, is possessed by the Orbs of the fix'd Stars and Planets. Also the motion of of the Planets proves the same. For seeing they are somtimes neerer the Earth, somtimes further off, which the Doctrine of *Paralaxes* teaches, and the appearing Quantity shews; for *Venus* appears somtimes so great that the unwary beholders take her for a new Star; and *Mars* is somtimes seen equal to to *Jupiter* in bigness: which cannot any otherwise come to pass, save because in the fluid and penetrable body of the Heaven, the said Stars come somtimes neerer the Earth, and otherwhiles go farther from the same. And how could *Mars* be somtimes higher, otherwhiles lower than the Sun, if both were carried in a solid Orb?

The Stars are moved by a faculty planted in them by God.

The Premises therefore considered, we must hold that in that same fluid, penetrable, most thin delicate, and invisible body of Heaven, *The Stars are moved by a power and faculty implanted in them by God their Creator*, without any violent and external impulse or carriage. For that God who willed and commanded, that the Stars by their Motion, should describe the Times, Daies, and Years, gave them power likewise to Effect the same. And if the Creator could put such Power into the Elements Earth and Fire, that in a most streight Line, the one should move down to the Centre, the other upwards from the Centre, why could he not give the Stars such a power as to move circularly? And therefore *Cicero* vainly wonders in his 2. *de Natura Deorum*, where this constancy comes in the Stars, this so great an agreement from all Eternity in such several motions, how it can be without Mind, Reason and Counsel. For this faculy of Motion is not quite void of reason and Counsel, but by the most wise Creator, it is granted to these his Forms and Instruments.

Why Astronomers retain the Orbs.

Mean while it hinders not, though the Circles and Orbs be retained by Astronomers as hypotheses. For such figures are not without cause used, to describe the motions of the Stars, as are described in the said Orbs, and Circles.

Heaven is a most simple Body.

Now this Heaven is a *Body most simple and most pure*, of a different nature from the Elements and therefore a *fift Essence* so called by *Aristotle*: which also is true nevertheless of the Stars. *It is void of all color cleer and transparent*, and therefore

The Heaven is not colored.

cannot be seen. For though as *Scaliger* saies in his 66. *Exercit. Sect.* 1. the Heaven seems to be of a blewish or saphire color: yet it rather seems so, than is so indeed. For even the Air also, though neer us it have no color, yet afar off it seems to be color'd. The Reason is, because it is thickened, not by composition of parts, but by disposition. For distance represents many parts to the sight, disposed al along in a visual line.

The

The said *Heaven is unchangeable and uncorruptible* (as also the parts) For there is not any body in the world, by which the Heaven or the Stars, can be affected or changed. Contrariwise, the Heaven has power to work upon these lower bodies, and does diversly affect them. For though the chief action upon these lower bodies, proceeds from above from the Stars: yet must not all active power be denied the Heaven it self, wherein the Stars are and are moved; seeing it also has its form, which can no waies be idle. Moreover the Heaven is the *greatest of all bodies*, since it imbraces all other bodies of the world in its Compass: also it has a *Spherical Figure*, because it is of all others the most capacious.

It is unchangeable.

The Heaven also it self works upon these lower bodies.

It is the greatest of bodies.

As to the Nature of the Stars, it is indeed commonly held, that they are the thicker parts of their Orbs; but the truer opinion is, that the most good and great God, did on the fourth day distribute that same primitive light, which he made the first day, into the Stars, and hence was the original of all this number of Stars. For it is absurd to think that first light returned to nothing, seeing it was good. Or if any man please to place that primitive light in the upmost region of the world, above the starry Heaven, and to make that upmost Region its mansion place; yet it must be confessed, that God the Author of the world, created the Stars themselves ful of light upon the fourth day; whereas he created the Heaven before, upon the second day. And this light is, doubtless, a most noble substance, most excellent, most simple, than which among all bodies, nothing is more beautiful, more sweet, nothing more admirable: by which all these sublunary things are enclined and cherished: without which this world would have no beauty: this as among bodies it is most beautiful, so it is the first and chiefest Image of the wisdom, beauty, power and goodness of the most high.

The Original of the Stars.

Howbeit, the inmost nature and Essence of this Light, is unapproachable and unsearchable by humane wit; and therefore we cannot in this darkness of humane understanding perfectly understand the nature of the Stars. For seeing the Essences even of those things which are about us in this lower world, are unknown to us; 'tis easie to see how little we can promise our selves concerning the knowledg of things so exceedingly remote.

Very like it is, That *every Star has its proper substantial form*, and as here below, Plants and Animals do by their forms differ from the Air wherein they live, and one from a nother, so also that the Stars differ both from the Heaven and one from another, by their specifick forms, which appears even from their essential proprieties and Effects. For the Stars have light, the Heaven has not; and the Stars do therby differ one from another; and Experience shews, that these things below are differently affected by different parts.

Since therfore we cannot pierce into the knowledg of the inner form and Essence of the Stars, let us weigh and consider these proprieties and effects which flow from the form and Essence of the Stars. And there comes here chiefly to be considered, Their Motion, Light and Shine, Heat and hidden Influences.

And in the first place the most wise and powerful Creator, has placed this power in the Stars, that every one is moved with a certain motion; and he that commanded them to describe the times by their motion, gave them a power to move and to perform what he had commanded.

The Motion of the Stars.

Now these Stars have a double motion. For some are moved with an equal motion in such sort, as they retain alwaies the same distance one from another, and these are commonly cal'd the fix'd Stars: others have divers motions, nor are they alwaies equally distant one from another, but now are joyned, and after a while separated, one while they are neerer another while further one from another; and those Stars are called Planets.

Some Stars are fix'd others Planets.

Which being so, they make two motions of the Stars, one whereby the fixed Stars are perpetually moved altogether, retaining the same distance one from another: the other is both differment for the motion of the fixt Stars, and thereby every Planet is moved after a peculiar manner. These motions are vulgarly termed the first and second motion, and they teach that the first motion, is that whereby the uppermost Sphere is carried about once in twenty four hours, and carries all the other Spheres with it from East to West; and the second they say is that which is proper to the rest of the Spheres, whereby they move contrary to the *Primum mobile* or first Sphere from West to East, some more swiftly, others more slowly: which

whether there are two motions of the Stars?

which distinction of motion we willingly allow the Astronomers, if they wil take it as an Hypothesis or supposition. Howbeit we conceive this distinction needlesly introduced into the Schools of Natural Phylosophy, and peradventure against the the Consent of Nature: and we think it no absurdity to say that all the Stars are moved from East to West, the fixed ones most swiftly, in the space of twenty four hours the rest by how much they are lower, so much the slower, and the Moon most slowly, much about the space of twenty five hours, only some minuts less.

For that seems not a sufficient Cause which they assign for their second motion, *viz.* Because we see the Moon or some other planet, which was joyned to some fixed Star, in the West or the South, after one or two daies, one or more degrees Eastward, that Star being left Westward, with which it was before conjoyned, it becomes nearer and therefore was moved from the West toward the East. For if you shall suppose all the Stars to move from East to West, and every upper Star to be swifter then the lower, there wil be the same appearance in the Heaven, and the lower which move more slowly will be left behind by the upper which are moved swiftly: which is more likely to be true then that the planets move towards the East. Let the Sun and Moon be joyned in one point Westward and let us suppose that the Sun once in twenty four hours and four minuts, and the Moon in twenty four hours, are carryed about the Heavens; when the day following, the Sun shal be returned to the same point, the Moon wil be yet distant therefrom almost twelve degrees, and will at last reach it after fifty one minuts are past. And this opinion which we propose *Plato* seems to have favoured in his 7. *de Legibus*, where thus he writes concering the Sun, Moon, and other Stars. *Every one of them goes round the same way, not many waies but one way: though they seem to be carried about by various and manifold waies. And that amongst them which is most swift, is not rightly judged to be most slow, and that which is most slow, most swift.*

Howbeit as to the period of the Stars, and their return (as they cal it) to the same point of Heaven; it comes all to one pass, whether you hold the Stars to be moved with one motion or with two. For the Moon being departed from one point of Heaven, after twenty nine daies or near upon, she is seen in the same again, which space is called *Mensis Lunaris*, the Moones month. The *Sun*, *Venus*, and *Mercury*, return to the same place in the space of about a year: *Mars* in two years; *Jupiter* within twelve years; *Saturn* in the space of thirty years; the fixed Stars in the space of 48000 years, which space of time they call *Plato* his great year: and *Plato* is said to have beleeved that when so many yeats are past, al things in the world shal return unto their old State.

Lux, Lumen, and *Radius, how they differ.*

In the next place we are to consider in the Stars their *Lux* and *Lumen*, Light and Shine, then which the whol world hath nothing more pleasant, and which are rightly called by *Franciscus Patricius* in the *fourth Book of his Panaugia*, the good and great God his greatest and best Instrument. And first let us see what *Lux*, *Lumen*, and *Radius* are, and how they differ one from another. Some there have been and still are in that opinion, that Light is a substance and the Form of the Celestial Bodies; but their opinion swerves from the truth; since no substantial Form can be discerned by the sight. We must therefore hold, that *Lux* light is a quality and Essential propriety of a lightful body, of it self perceptible by the sight. But what is the first subject of light, or, whether all the Stars shine with their own light, or borrow it from the Sun, herein the opinions of Phylosophers do vary. For some hold all the Stars shine with their own proper light, others hold they al borrow their light from the Sun, and others again hold that only the Moon borrows her light of him. This is our opinion: That all the Stars do indeed receive some light from the Sun: yet that they have also some light of their own. Both which we are taught by experience. For first we may chiefly observe, it in the Moon, which in regard of her several posture to the Sunward, hath various Appearances, in regard of the Variety of light which she receives from the Sun: the same is to be seen in the rest of the Planets, which are observed to be brighter or darker in regard of their several postures to the Sun. And therefore *Orpheus* calls the Sun the quickening Eye of Heaven: *Heraclitus*, the Fountain of Heavenly light; the ancient Phylosophers, the Heart of Heaven; and the *Platonists* placed the Soul of the world in the Sun, as *Marsilius Ficinus* tels us in *his Book de Sole Ch.* 6. The latter may be observed not only in the Moon, but also in the other planets. For in the

The Stars shine both with their own and borrwed light.

Ecclipse

Ecclipse of the Moon, we see she has some light, and the same appears also after her conjunction. when we may many times see that part of her which is from the Sun, by means of her inbred light: which also any one may observe in the planets which are lower then the Sun, as *Franciscus Patritius* teaches, in the 7. *Book of his Panaugia.*

From the light proceed *Lumen* and *Rady*, shine and Beams, which *Franc. Patritius* saies are two divers things in the 3. *B. of his Panaugia.* The truth is, where there are Beams there is shine, but there may be shine where there are no beams or raies. For in a Chamber which looks towards the North, and is not right against the Sun, there is a shine at noon tide, but no beam or Raies. And therefore a Ray or Beam as he there shews, is as it were a secondary Light, or a brightness arising from the first light, and shooting to a right and an acute Angle. And *Lumen* or shine, is as it were a third light, flowing from the first and second, not diffused into Lines and Pyramids, but loosely shed abroad. First therefore there is *Lux* light in the lucid Body; then there is *Radius* a Beam which is an image of the light, diffused from the lucid body in a right Line; thirdly *Lumen* or shine, which diffuse it self obliquely, aside the falling of the raies into all parts of the *Medium.* And indeed there seems to be some difference between a Ray and shine, or at least it is one thing to represent the light as a visible object and to offer it to the sight, and another thing to Illuminate the Air. For light seen from a dark place, does not enlighten all the air, betwixt the eye and the lucid thing; and that light which enlightens the Air hardly a furlong, is seen some miles of, in the night time; yea and the Stars themselves, are seen by us at an huge distance in the night; though they do not illuminate the whol Air. Which difference causes, that there is a twofold definition of *Lumen* or shine. For absolutely considered, shine is the image of light, or the quality of a Lucid Body, whereby it communicates it self to other Natural things, affording it self to their sight, and cherishing them. But as *Shine* is considered in respect of other things which it inlightens, it is the act of Colours whereby they become visible.

What a Beam or Ray is.

Now concerning *Lumen* or shine some Controversies are agitated. And first touching the Nature thereof there hath alwaies been great dissensions amongst Physophers, which are not yet composed, so that it is dangerous to determine any thing in this point. Howbeit I shall breifly deliver, what seems probable in so obscure a matter. Now the question is whether it be a substance or an accident. For there are very many who hold that it is a substance, some corporeal, others incorporeal. And they that say the Raies and shine are a substance, are cheifly moved thereunto, because the shine and Beams are diffused through the Heaven and the Air, and that in a moment; which seems improper for an accident, which passes not out of one subject into another and because falling upon a dark and solid body they are reflected and leap back again. And those arguments could almost move me unless the same arguments, did make as much against all visible, yea, and sensible species or representations. For, neither are other visible species moved with the motion of the Air, and they are in a moment diffused through their whol Sphere: Yea, and some also, witness the Eccho, is reflected And therefore as oft as I think of this matter, I thus complain of the obscurity of Nature with that most learned Physopher and Physitian *Hieronymus Fracastorius.*

Whether light is a Substance or Accident?

What shall I say, Poor wretch, that I do, what life that I lead now?
Restless in my mind, and alwaies busily searching
After Nature, who still flies, and leaves me behind Her.
And when a while sh'has shewd her self, then straight in a moment
Proteus like to a thousand shapes, She turns Her Visage.
And so She leaves and vexes me, continually mourning,
For lost Labour, and old Age, so vainly bestowed.
For when of late I busily Sought, those thinly appearing
Images that flow from things and shed them all over,
And to the Wayles woods went alone to the Silent
Secret shades, there I found, how by these shews I deluded
Was, though they smite alwaies our sense and still they assail us.
Passing and Repassing through the Doors of our senses,
Haunting our Soul all day, and in the night when She sleepeth:

These are Hexameter Verses in Imitation of the Latine.

Lumen, light, or shine is an accident not a substance either corporeal or incorporeal.

Yet if we may say what is probable, that opinion seems to be trueſt, which does affirm that light is neither a Body nor a ſubſtance incorporeal, but an accident, and quality produced by a lucid Body in a tranſparent Medium whoſe act it is. For if the light were a body, ſince it is diffuſed through the whol Air, and is received by all the parts of the Air, there would be a penetration of Bodies. Moreover, if it were a Body, it ſhould be moved ſucceſſivly in time. For a Body cannot be moved in an inſtant through a Medium filled with another Body: becauſe the middle Body through which it is moved, would reſiſt the ſame in its motion. But we ſee the light ſpred far and near in a moment. And that it is no incorporeal and ſpiritual ſubſtance is hereby apparent: in that ſpiritual ſubſtances fall not under our ſenſes, or have dimenſions; both which are true of Raies and Light.

Whether light be a real or intentional accident.

That light therefore is no ſubſtance but *a Quality*, hath been made appear. But whether it be a *real* or *Intentional* accident as they Phraſe it, is a great queſtion amongſt the expoſitors of *Ariſtotle*. And in the firſt place we muſt rightly underſtand the ſenſe of this queſtion. An intention and an intentional being, though it is commonly taken only for that which depends upon the operation of our mind, and without it, is nothing, *viz.* For an intelligible ſpecies which repreſents ſomwhat without the Soul to our underſtanding, either immediately, ſuch as are the firſt notions, or mediately by the mediation of the firſt, ſuch as are the ſecond notions: yet here in a more general ſenſe, the word Intention, ſignifies that which is the Image and repreſentation of another thing without the Mind, that is to ſay the repreſentation of a ſenſible ſubject in the Medium; and ſo an intentional being is taken for every ſpiritual ſpecies repreſenting a real object, whether it be ſenſible or intellectual. So the Collor which is in our Cloaths or on a tree, is called real; that which is in a Looking-Glaſs, and is the Image of the color in the Cloaths, and that which from the tree is ſhed upon the Cloaths of him that lies under it, is ſaid to be an intentional color. And in this ſenſe we hold, that the ſhine, is an intentional quality: yet that nevertheleſs, it is a real being, as having its own Eſſence, without the operation of our mind, yea, and that it hath a more noble office then other intentional ſpecies ſo called, and that it is ordained out only for repreſentation, but alſo for other effectual operations. Others do thus explain the matter. That light is a ſpiritual quality, not principal or real, or rather material. Now there is a great difference betwixt principal or material, and ſpiritual Qualities. For the former are not the image of another thing; they are received in the ſubject ſucceſſively, and are moved in time according to the motion thereof; they are not totally in any part of the ſubject; they are not many of the ſame ſort in the ſame ſubject, differing only in number, and kept unconfuſed and diſtinct. Whereas the contrary holes in ſpiritual Qualities; as we may ſee in *Lumen* or ſhine. For ſhine is the Image of Light; 'tis ſhed through the whol Air in a moment; it is not moved according to the motion of the ſubject. For though the Air is toſſed with winds yet the ſhine of light is not moved thereby. Every part of the ſhine repreſents the whol lucid Body from whence it comes. and in the ſame part of the Air, many images of lucid Bodies or lights are kept diſtinct and inconfuſed.

The diviſion of a Ray or Beam.

A Ray or beam is divided into a right, a reflex, a fract, and a refract: and that is termed right or ſtreight, which paſſes from the lucid Body, without any hindrance of a dark Body. That is reflex, which lighting upon a thick dark Body rebounds back. That is fract, which paſſes out of a thin into a groſs Medium, as that which comes out of the Air into the Water. That is refract, which comes out of a thick Medium into a thin. Howbeit *Scaliger* oppoſes the terms of a reflex and fract *Radius* in his *Exercit.* 75. *Sect.* 10. and conceives, not without cauſe, that that which is commonly called reflex, ſhould rather be termed fract: for the reflex commonly ſo called, is not one Beam but two; one falling on, and another rebounding back: and that the fract, ought rather to be termed ſhed. or powred abroad. For that is one Ray, which is in the Water and in the Air; differing only in the variety, and denſity of parts, being thinner in the Air.

The Heaven & the Stars do not therefore heat, becauſe they are fiery.

After *Lux* and *Lumen*, Light and Shine, the Heavenly heat comes to be conſidered, and the cauſes thereof to be ſearched into. And although, not only ſome of the ancients, but of the latter writers alſo, have been of opinion, that the Heavens and Stars do therefore heat, becauſe they are of a fiery Nature, and have in th m

Heat

Heat formally, as a Natural accident, by means whereof they again heat other things: yet that opinion is by most men rejected, and it is resolved, that the Heaven though it is not of its own Nature hot, hath yet a power of heating these inferior Bodies; and as *Scaliger* conceives in his 23. *Exercitat.* that the heat is indeed from the Stars, but not in them, but in these bodies beneath; and in the 74 *Exercit. Sect.* 2. that calefaction or heating does primarily and of it self belong to the Sun, without any Medium, as to a first Body, the author of Heat, but not the first subject thereof. But if any man shall hold, that the Stars are hot, not with a fiery heat, but with an heat proper to themselves, I see not by what solid reason, he can be confuted. For there is no cause why the Heaven should be void of all qualities. And Heat seems to be an individual companion to light. Nor need any man fear, that the Heaven should be corrupted by these inferior Bodies, if it be hot. For since the Heaven does not participate with these inferior bodies, either in the Nature of its Essence, or its Qualities: the inferior bodies no waies act upon the Celestial. Nor was *Carden* the first that held heat to be in the Heaven, but the *Arabian* Phylosophers long before, and *Mirandulanus* and others who followed them. For thus writes *Joh. Picus Mirandulanus* in *Astrolog. Lib.* 3. *Ch.* 4. Heat follows light as a propriety thereof, not fiery heat, nor Aereal but Celestial; a proper quality of the Heaven, as light is. I say an heat most effectual and saving, peircing al things, cherishing all things, moderating all things.

How Heaven heats these lower Bodies.

From the Premises some light arises to that Question, how Heaven heats these lower Bodies? 'Tis commonly held that Heaven heats them, by its motion and light. But touching motion, 'tis a doubtful case. It cannot indeed be denied, that a swift motion of a solid Body, does heat the Air next unto it: since experience shews that to be true. For motion does heat by attenuating, it makes the parts of the Air thin, and so heats them; yea and if it be more vehement, turns them into fire. For the fire being, as hotter, so thinner, then the Air. If the Air be a little more attenuated, the Form of the Air can no longer subsist in a thin matter, but the form of Fire is introduced. But this is doubted, whether the Heavens motion, produce heat in these lower Bodies? some holds the motion of the Heaven pierces as far as the Earth, yea and into the inmost bowels thereof, and produces heat by making the Air thin, and by grating thereupon. But contrariwise, *Scaliger* in his 23. *Exercit.* saies, that he did not beleeve the Son of *Roes*, who said, that the Heavenly Bodies did not warm by any heat in themselves, but that through the swiftness of motion, both heat and light came from the Stars, by their motion grating upon the Air; and held that the cause of the motion of Heaven was, that the Stars might communicate their virtues to the parts here below, but not that they should heat. And indeed great cause there is to doubt, whether the Heavens motion do heat the inferior Bodies. For they who hold that the Heaven by its motion, warms these inferior Bodies, do all presuppose, that the Heaven is a solid Body, by the Circumvolution whereof, the neighbouring Elements are wheeled about. But that this is false, hath been already declared. Nor can the bodies of the Stars perform that with their motion, nor does their motion reach to these lower bodies, by reason of their so great distance. Nor does that fire which is next the Moon, receive heat from their motion. For it hath the highest degree of heat before, by its own Form. For if it were not in the highest degree hot, it were not fire. And therefore the fire hath not its essential heat from the Heavens, but an accidental heat, as the most subtile *Scaliger*, in his 23. *Exercitation*, saies subtilly, Yea, and obscurely enough. For what heat can be added to that which is hot in the highest degree? But peradventure, that is thus to be understood. That the fire receives not essential heat from the motion of the Heavens, but hath it from its own form; but it is nevertheless preserved by Heavens motion.

Whether the motion of Heaven be a cause of Heat?

The fire has not its essential heat from Heaven.

Now it is commonly held a clear case, that the shine is the Cause of heat: though that of *Scaliger* in his 75. *Exercitation*, may give occasion of doubting. *Heat* (saies he) *is an accident bred by the Heavenly Bodies, and through the Heaven, without any affection thereof, brought to the Aire, and that not by the shine, but both with and without the shine.* And indeed the Raies or Beams, rather then the shine, are the cause of Heat.

The shine is not the Cause of heat, but the beams.

For there is not Heat, where ever there is shine, and in Winter, the Cause of the cold is not want of light; seeing in the middest of Winter, there are many times

as clear and bright daies as in Summer, but it is the obliques of the Suns beams. And therefore when *Lumen* or shine, is said to be the cause of heat; the Beams or raies are to be understood.

How the Raies or Beams do heat?

But how the Raies or Light does heat, Doctors are not yet agreed. Some are of the opinion that light therefore heats, because it rarifies and makes thin the Air, after the same manner as motion does; and that the doubled Raies do it in a special manner. For though the incident and single Raies, have also the power of heating and attenuating: yet their force, they say, is weak; but the doubled Raies beating one against another do more strongly grate upon the Air and rarifie the same. Howbeit many do contrarywise hold with probability enough, that the light does of its own Nature produce heat, and that a Ray compounded of a streight one and a reflex, does heat more then a simple, not because two Raies smiting one against another do grate upon the Air (for how should that great upon the Air which is no Body?) but because, that portion of light which was to go streight forward, being hindred by an Opake Body is reflected, and joyned with the incident Ray, and so virture conjoyned becomes stronger then that which is dispersed. Hence some Raies are stronger then other some to excite Heat. For those which fal perpendicularly, and reflect upon themselves, are of al others most effectual: and those are next these most powerful, who go least into oblick Angles; but the more they go oblickly from the point of incidence, the least heat they raise. For the nearer the Sun comes to our Zenith and the directer his beams fal upon us; so much the greater heat is caused. And it goes contrariwise in the Winter, when the Sun darts his Beams upon us oblickly.

Perpendicular raies most effectual.

The Stars are not placed in Heaven only for ornament sake.

Now it will be worth our while to enquire whether the Heavens do not also some other waies work upon these inferior Bodies. There are some Men found so silly as to dare to deny, not only other more noble actions of the Heavens upon things below, but also their power of heating; and to hold that the Stars were set set in the Heaven only for ornaments sake like Golden Spangles; of which sect of men *Nicho. Frischlinus* seems to have been. But away with such Barbarousness! *Asclepius* was long since of a better understanding, when he thus wrote to King *Ammon*: the good operations of the Sun, are not terminated in the Heaven and Air alone, but even in the Earth, they pierce into the deep bowels thereof: from whose Judgment, the learned Men of latter ages, have not receded, but all have taught, that Heaven acts upon these lower Bodies, and is a cause of much good to mortal Men. For nothing in the whol Universe is idle, nothing made in vain, but all things as they have their Forms; so by them they operate and act. Experience not to be contradicted does witness the same. For we see and feel, how that by the Heavenly Bodies, through the various augmentation of heat, the changes of times and seasons, and the vicissitude of generation and corruption are caused; tempests are raised; the humors of Animals, especially shelfish do encrease and lessen according as the Moon Fils or Wains. Let them go therefore, who deny the Heavens to have any virtue, and let us consider: whether *besides their light the Heavenly Bodies do work upon things below, also by another peculiar and hidden way, which they call influence?* Most indeed of those who write against Astrology, say that the light only of the Heavenly Bodies, which is variously communicated to several places according to the variety of the Heavenly motions, is of it self sufficient to produce all the effects, which are produced by the said Bodies. Yet we must hold the contrary, *viz.* That the Heaven, not only by its motion and light and the heat thereon depending, but also by certain peculiar powers, which they call influences, does act upon these lower Bodies. For many effects proceed from Heaven, which cannot be ascribed to light. For light may be kept out, by a dark or dense Body; whereas many things are generated by the concurrency of Heaven in the profoundest Cavities of the Earth, under the Waters, whether neither the light of Heaven nor the heat produced thereby can pierce. And verily since there are in the Load-stone and other vulgar things, rare virtues to act upon distant things, without any light: we ought not to deny the same to the Heaven, so Magnificent a Body.

Whether the Heaven works by influence upon the inferior bodies.

The Heaven works upon things material, but does not immediately act the same.

Howbeit we must enquire how far this Influx of the Heavens extends it self, and upon what things it works. It is not to be denyed, that *the Heaven acts upon all material and merely Natural things*: but it is a question, *whether that Celestial Influx,*

do

do work upon our Soul and will. All found Phylosophers do answer *that the Stars do not work directly and immediately upon our wils.* For since the Heaven is a corporeal and material Agent, it acts only upon corporeal and material things, but our will is a power not allied to matter. Mediately nevertheless and indirectly, *viz.* by Mediation of the Organs of our Body, which being variously Qualified do move and provoke the Fancy and the sensible appetite, and thereby the will; the stars may encline our wil to this or that. Upon which ground 'tis also commonly said, that Mens manners follow the temperament of their Bodies. Howbeit, neither the temperament, nor the stars by the temperament do compel but only encline. For though any one through aboundance of Choler in his Body, be enclined to anger, and through flegm to idleness: yet it remaines in the liberty of his will, either to refrain or give the reines to his anger; or to give himself to labor or to take his ease. Hence we may easily know what to think of Astrology, which is said to foretel future events, by observation of the Heavenly Bodies. It is not to be denied, that Astrologers may many times probably foretel Tempests, Rains, Barrenness and fruitfulness of the Earth, Diseases, and other such like Natural effects, which Naturally depend upon the disposition of the sublunary matter in respect of heat cold, Moisture, Driness, and other such like qualities, and may betide sublunary Bodies. Yet Experience shews that they cannot alwaies certainly foretel such things as these.

What is to be thought of Astrological Predictions?

For seeing there is requisite to these kind of effects, not only the influx of the Heavenly Bodies, which is the universal Cause, but also a certain disposition of the Earthly Globe, which affords matter to Rain and other Meteors, and also of the Matter and sublunary qualities, which are all unstable and subject to change, and cannot be sufficiently discerned by the wit of man: the judgment and prognostication cannot alwaies be firm and certain. Much less can any thing be certainly foretold concerning human actions which depend upon the wills of Men, and touching things contingent and fortuitous. For though these things depend in some measure, as hath been said, upon the temperament: yet because our temperament does not compel our wil, and the Heaven it self is not the immediate and principal Cause of the temperament, it is also hard in this Case to foretel any thing with certainty.

Nor dare the founder Astrologers themselves attribute any greater efficacy to the Stars, nor to themselves any greater ability of Prediction. Whence also *Ptolomy* himself, *de Pred. Astronom. Lib. 7.* teaches that those things only can be foretold, in the Calculation of Nativities, which depend upon the temperature, *viz.* That the Body of such an one is so and so, and his manners so and so, whence such and such events will follow, because the quality of the Heaven suitable to the temperament, is fit to produce a good habit, or contrary thereunto. And he himself saies in terms expres, that those who foretel other things, which have not Natural Causes, are cousening fellows, that abuse the people. *Ptolomy* therefore the Prince of Astrologinians hath set them their true bounds and limits: within which nevertheless, all the Predictions which he delivers in the following Books, can hardly be contained. And the same Author also teaches in *Lib. 1.* That many things besides the Heaven, do concur to the Temperaments of Particular persons, and that the seed falling from the Bodies of their parents, hath the chiefest force, also that the Countrey makes a difference, and that education and Custom have no smal force to change the temperament.

The Causes of many Sympathies and Antipathies doubtless, betwixt the Heavenly Bodies and these things below, do proceed from these hidden influences, the Inquisition whereof does belong unto another place. Mean while let us hold with that opinion of the Chaldæans and Assyrians, recorded by *Psellus*, viz. *That there is a Sympathy betwixt things above and things below.*

As to the other adjuncts of the Stars, *viz.* Their Figure and quantity: that their Figure is Spherical is Demonstrated. First, By the Illuminations of the Moon: Secondly, By the Ecclipses; the sight of all Men wherever inhabiting: since plain Bodies do change their Figure as often as those who look upon them from below, do change their place and Situation.

The Figure of the stars is Spherical.

And whereas the Stars appear flat like dishes; that comes from their over great distance, for all lines drawn from the Eye to the surface of a Sphærical Body fat off

off, appear equal to the middle or perpendicular line, drawn from the Centre of the Eye, to the Centre of the spherical body. *Vitello B. 4. ch 65.*

Two sorts of Stars fixed, and wandring or Planetary.

The Stars are of two sorts, the Planets and fixed Stars, as was said before. Those are called fix'd Stars, which are in the uppermost part of Heaven, and in their motions do alwaies keep an equal distance one from another. The Planets or wandring Stars, are not so called, because they really wander, or are moved with an uncertain motion, but because though they hold a certian rule in their motions, yet in respect of the fixed stars, they have a more free kind of motion, and are somtimes in one, another while in another part of the Heavens.

The number of the Planets.

The Planets are commonly reckoned to be but seven. For though *Favorinus* in in *Gellius B. 14. ch. 1.* did doubt whether there were only seven Planets; and supposed there might be more, though not seen by us, in regard of their exceeding either splendor or altitude: yet because neither experience, nor reason can evince there are more, the vulgar number has been retained hitherto.

Howbeit amongst the late Astronomers *Galilæus* a Florentine, has found out certain new Planets, formerly not known or seen by any man, by help of his optical Tube or prospective Glass; which he observed to move about *Jupiter*, and cal'd them the medicean Stars (from *Cosmos medices* the Duke of *Tuscany*, so called, to whom he dedicated his labors) also the Jovial Stars or *Jupiter's* Stars: whose number and motion he described in a Book called *Siderius Nuncius*: wherein he described other things by him observed in the face of the Moon, in innumerable fixed Stars, the Galaxy or Milky way, and cloudy Stars, worthy of consideration.

The number of the fixed Stars

Astronomers at this day reckon the fixed Stars to be 1022. but there are more indeed and in truth. For even *Pliny* in his *Natural History B. 2. ch. 41.* saies that skilful men had reckoned 1600. remarkable for their effects and use; and those that have in our times sailed into the South parts of the world, relate that they have observed more. And therefore though we may grant to the Astronomers, that there are so many fix'd Stars which may evidently be observed, and may conducce to a astronomical Calculations: yet if any shal contend that there are indeed no more, we shal stop his mouth with that of *Austin* in his 16. *B. de Civitate Dei ch.* 23. *Whosoever* (saies he) *boast that they have counted and set down the total number of the Stars, the Authority of this Book* (Gen. 15.) *does condemn them:* and that there are indeed more, the observation of the foresaid *Galiæus*, does evince.

The Order of the Planets.

Also there is some controversie touching the order of the Planets: *Metrodorus Chius*, *Anaximander* and *Crates*, as *Plutarch* informs us in his *2. de Placit. Phylos. ch.* 15. held the *Sun* to be highest, next him the *Moon*, after her the fix'd Stars and Planets. *Plato* and all the Greek Phylosophers in a manner, did beleeve the Sun to be next the Moon. *Ptolomy* placed the Sun in the middest of the Planets, and made such an order of the Planets, as that the Moon should be lowest and next the Elements, *Mercury* next above her, *Venus* next above him, in the fourth place the Sun, in the fift *Mars*, in the sixt *Jupiter*, in the seventh *Saturn*, in the eighth the fixed Stars, which opinion is by most men followed. For both the observation of the Parallaxes, and other Astronomical reasons do confirm the same.

For the greater Parallaxe a Planet has, the neerer it is to the Earth; and the lesser parallaxe, the further from the Earth. But amongst all the Planets, the Moon has the greatest Parallaxe; *Mercury* somwhat a lesser; *Venus* yet a lesser; and the Sun the least. Whence we collect, that the Moon is neerest the Earth, *Mercury* a little further off than she, *Venus* more remote than he, and the Sun more remote than *Venus*. Moreover the Moon obscures and takes out of our sight *Mercury*, *Venus* and the *Sun*; which could not be, if these Planets were lower.

Nevertheless, although this be certain, and the reasons aforesaid do sufficiently demonstrate, that the *Moon* is below *Mercury* and *Venus*: yet it is not thereby proved that *Venus* is higher than *Mercury*. For suppose the *Moon* obscure *Venus* and *Mercury*: yet it does not hence appear, whether *Mercury* or *Venus* be next the *Moon*, or whether *Mercury* be below or above *Venus*. Nor do the Parallaxes demonstrate the same. For though they teach that the *Moon* is next the Earth, because it has the greatest parallaxe: Yet that which is vulgarly reported of the Parallaxe of the Sun, *Venus* and *Mercury*, is not so certain. For latter Astronomers have observed, that *Mercury* has many times the same Parallaxe of the *Sun*, *Venus*

oft

oft times the same, and often times also a lesser. Which cause moved *Tycho Brahe* that most noble Astronomer, to invent a new disposition of the Planets; with which as more probable, most Astronomers at this day content themselves, til some body shal teach them better. But whatever Scituation of the Planets we shal allow, yet this remains certain, that it cannot be defended, unless we hold, as has been shewed before, that the Heaven is no solid body, and that there are indeed no Orbs therein of which it should consist. Which if it be not allowed, but we shal include the Stars in their Orbs; there must needs be penetration of bodies, if their motions be salved; which the motions of the *Sun*, *Venus*, and *Mercury* do chiefly declare. And most probable it is, which also I propounded before, that there is not a double motion of the Planets, one from East to West, another from West to East, but that all the Planets are moved from East to West; since Entities or Beings are not rashly to be multiplied, and without necessity: and since it suffices that the Stars have an internal principle of their motion; 'tis needless to ad an external and violent one. *Aristotle* saies rightly in his 1. *B de Celo ch.* 2. when he demonstrates, that a violent motion is contrary to a natural, and that a simple motion suits with the celestial bodies being simple; and that as the fire is moved upwards, the Earth downwards, so the heavenly bodies are naturally moved with a circular or wheeling Motion.

The distribution of the fixed Stars into Constellations.

Astronomers have reduced the most considerable and visible fix'd Stars, for better knowledg and memories sake, into certain figures resembling living Creatures and other things, which they cal Constellations. Which distinction of Figures and Constellations is of exceeding Antiquity, and was known either before, or soon after the flood; witness, not only the most ancient Poets *Hesiod* and *Homer*, but also the holy Scriptures: for in *Job* 9. 9. mention is made of *Arcturus*, *Orion*, and the *Pleiades*.

Now credible it is that the Astronomers were Authors and Inventers of these constellations who were studious of the Heavenly bodies, also Sea-faring men, as appears by the Southern Constellations, found out by the Navigators of the former Age and by them named, of which *Virgil* was aware, when he wrote,

Navita dum stellis numeros & nomina fecit.
When the Sea-men, numbred and nam'd the Stars.

Also Husbandmen, who in daies of old wanting the benefit of Calendars or Almanacks, were fain to begin their Labors, according to the appearance of certain Stars or Constellations. Whence also it happened, that some Stars have divers names, according as the Astronomers, Sailers, or Husbandmen cal'd them.

The Constellations differ from the twelve Houses.

Here also is to be observed, that the signs of the Zodiack or Austerisms differ from the twelve houses, each of which has thirty degrees, according to which the motions of the *Sun*, *Moon* and other Planets are reckoned, being obvious to the mind, but not to the Eye sight. But the signs of the Zodiack, are Stars visible to the Eye, reduced into certain Images, which Images, are not equal, but some greater, others lesser. For the Constellation of *Virgo* than *Libra*, and *Libra* than *Gemini*.

Now these Constellations are divided into those of the Zodiack, and those without the Zodiack, which are Northern or Southern. For the Zodiack is the pathway of the Planets, out of which though the Planets, excepting the *Sun*, do decline some whiles to the South, otherwhiles to the North, from the eccliptick which is the *Sun*'s path: yet they never wander out of the latitude of the Zodiack which consists of sixteen degrees. The signs of the Zodiack are *Aries*, the Ram; *Taurus* the Bul; *Gemini*, the Twins; *Cancer*, the Crab; *Leo*, the Lyon; *Virgo*, the Maiden; *Libra*, the Ballance; *Scorpio*, the Scorpion; *Sagitarius*, the Archer; *Capricornus*, the Goat-Buck; *Aquarius*, the Water-man; *Pisces*, the Fishes.

The Northern Signs are twenty one. The *Bear greater and lesser*; the *Dragon*; *Bootes*; *Ariadne her Crown*; *Hercules*; *Cepheus*; *the Harp*; *the Swan*; *Cassiopeia*; *Perseus*; *Heniochus*; *the Serpent*; *Serpentarius*; *the Arrow*; *the Æagle*; *the Dolphin*; *the Pegasus, or Flying Horse*; *The little Horse*; *Andromeda*; *the Triangle*.

The Southern signs as yet discovered are fifteen: The *Whale*; *Orion*; *Eridanus River*; *the Hare*; *the Dog*; *The little Dog*; *the Ship Argo*; the Hydra or *Water-shake*; *the Cup*; *the Crow*; *the Centaure*; *the Woolf*; *the Altar*; *the southern Crown*; and *the southern Fish*.

But

But *Americus Vespacius*, and they who after him have sailed the southern parts of the world, do aver that the southern part of the Heaven, which has been yet unknown, is adorned with many very bright and remarkable Stars: which in imitation of the Ancients they have reduced into certain Constellations, by them thus named; the *Triangle*; *the Peacocks Tail*; *the Camel*; *the Indian Bee*; *the Crane*; *Noahs Ark*; *the Hornet*; *the Cross*; *Touta*; *The Water-snake*; *the Clouds*; *the Phœnix*; *the River Indus*. All which Constellations, both old and new, may at this day easily be known by the Globes artificially made for the same intent.

The Stars divided into tribes.

The Stars are also divided according to their magnitude, into six Orders or Magnitudes; and some are said to be, of the first; others of the second; others of the third; others of the fourth; others of the fift; and others of the sixt magnitude: which are every where reckoned up by Astronomers. Yet this is to be observed, that the Stars which are said to be of the same magnitude, are not all really of the same Quantity or Splendor; for the *Syrius* or *Dog-star*, does far outstrip all other Stars of the first magnitude.

What the milky way is

To these heavenly bodies belongs also questionless the Galaxia or milky way: now it is nothing but a Circle or Zone rather of a white color, to be seen a nights in the Sky, reaching from North to South; and dividing the Heaven into two Hæmispheres or half circles: the progress and carriage whereof *Pliny* in his 18. *of Nat. Hist. ch.* 29. has briefly described, and *Manilius*, more largely, in the first Book of his Astronomical Poem.

Touching the nature thereof, sundry men are of sundry minds. We, omitting the Poets fables touching *Juno*'s milk a part whereof fel upon this region of Heaven, as *Hercules* was sucking, as *Cælius Rhodiginus* relates in his 6. Book Ant. Lect. Ch. 7. or concerning the burning of the world by *Phaeton*; the fight of *Apollo* against the Giants; of the way of souls; of the seat of the *Heroes* or *semy-gods*; and the opinions of others reckoned up by *Aristotle in the* 1 *Meteor. Chap.* 8. *Plutarch* in his 2. *de plac. Philos. ch.* 1. *Picus Mirandula* in his *Exam. Van. Doct. Gen. l.* 7. *c.* 12. we shal in this place only consider whether the *Via lactea*, be somwhat that is Elementary and a true meteor, or some heavenly thing. *Aristotle* in the place newly alleadged, saies the *via lactea* is not in Heaven, but in the Air and consists of an hot and dry exhalation, gathered into that place, where are the greatest number of largest Stars, being drawn up by the said Stars; so that it is as it were a great Comet, and is perpetuated, by the continual and perpetual attraction of vapors, caused by the great abundance of Stars, in that place.

Whether the Via lactea *be a meteor?*

Nevertheless divers most noble Phylosophers and Astronomers, have rejected this opinion of *Aristotle*, for these reasons chiefly. First the perpetuity of the *Via lactea*: for seeing all meteors are somwhat disorderly made, nor is there alwaies matter enough, of the same figure, or color for meteors, nor is it alwaies carried to the same part of Heaven: the *Galaxie* or milky way, if it were a meteor would not be alwaies, nor of the same magnitude, figure, color; nor alwaies in the same place. Again if the *Via lactea* were not in the Heaven but in the Air, it would not be alwaies seen in the same place of Heaven, and about the same Stars, and would admit some parallaxe; after the same manner as Comets, which are in the Air, in this Region appear under one Star, in another Region under another. Howbeit, experience teaches the contrary, which witnesseth, that for so many ages of years the milky way has alwaies been seen, when the Sky is clear, in the same place, of the same greatness, shape and color, and in all places, about the same Stars.

Nor has the opinion of *Franciscus Picolhomineus* any place, who that he might some waies defend the vulgar opinion, saies that there is a twofold *Galaxie* or milky way; the one Celelestial, which is an abundance of shining Stars, in the eighth Sphere; the other the Effect of the former which is an abundance of dry exhalations, brought together into the shape of a Zone Girdle or Swath-band, in the upper Region of the Air, apt to be inflamed, placed under the Heavenly *Galaxie*, and preserved thereby; which by reason of the Light it receives from the Heavenly *Via lactea*, presents unto us the resemblance of a large white Way or Road. For though it be true, that a greater company of Stars, wil more heat and raise up more vapors: yet no sufficient cause can hence be assigned, why the *Galaxie* or *Via lactea*, should appear alwaies of the same Greatness, and Figure, and in the same place. For to the

the constitution of a meteor, there is not only required, the force of one or more Stars, but also matter, and that after a certain manner disposed: which because it is fluent and unstable, and is wonderfully changed by reason of the Influx of so many Stars, no meteor can be perpetual, constant, and alwaies return in the same measure and manner: nor does the *Sun* nor any other Star, yea though in the same position, or returniug to the same place, raise the same tempests, nor can they cause the breeding of the same meteors, by reason of the plenty or penury, or the various disposition of the exhalation.

That opinion therefore of others is more probable, that teach, the *Via lactea* to be a collection of very many and very smal Stars, which they cal *Sporadæ*, in the eighth Sphere, which because of their smalness and abundance, cannot be distinctly seen, so that their light being jumbled together, represents to our sight a white, or milky color. To this opinion others do also add: that this part of the Heaven is a little more compact than the rest, and by reason of its compactness comes neer to the nature of Stars, and therefore both by its own light, and by that which it receives from the other Stars, it appears more bright than the other parts of Heaven which are more thin and transparent, and is of a remarkable whiteness.

Divers Opinions of the Nature of Comets.

Next to the Stars we ranck Comets; and truly there is an extream diversity of opinions touching their Nature. *Anaxagoras* and *Democritus* held that a Comet was the gathering together of divers Planets, which because they were met in one place, by the mingling of their lights they seemed to make one Star. The *Pythagoreans* taught that a Comet was a Planet distinct from the seven vulgar Planets, which commonly lies hid under the Sun-beams, and by reason of the splendor of the neighboring Sun cannot be seen: howbeit sometimes, after long Intervals, it departs from the Sun and comes into sight, which also commonly happens to *Mercury*. *Hippocrates Chius* and his Disciple *Æschylus*, did consent with the Pythagoreans, that a Comet is a Star: yet herein they dissented, in that the former held the tail of the Comet to be a part thereof; but these latter held the tail to be vapors lifted up on high, and neer the Comet, receiving the raies and light of the Sun, and so representing a stream of Hair. Howbeit *Aristotle* reckons up and refutes these opinions in his 1 *Meteor. Cap.* 6. *Seneca* in the 7. *Quest. Nat. Cap.* 11, 12. *&c.*

The Opinion of *Epigenes*, which *Seneca* relates and refutes in his 7 *Book of Nat. Quest. ch.* 4. *&c.* was, that Comets did arise, when moist and dry exhalations being shut up in one Globe, by reason of the internal Spirit and the discord of contrary bodies, were agitated and whirled about. For then that same force of the Wind going round about, did by its motion inflame whatsoever it caught, and lift it on high, and that the shining of the Fire and the Comet did so long last til there was no more fewel to feed it, which fewel ceasing the Comet ceases. The Opinion of *Aristotle* though it differ in part, does mostly agree with this. For *Aristotle* teaches, that a Comet does not consist of Celestial but of elementary matter, namely of plenty of fat & thick exhalations, raised into the upper Region of the Air and there set on fire. *Plutarch* in his third *de placit. Phyloſoph. ch.* 2. besides the opinions of the Pythagoreans, *Anaxagoras*, *Democritus*, *Aristotle*, *Epigenes*, relates also the opinion of *Strato*, conceiving that a Comet was the light of a Star, comprehended in a thick Cloud, as it happens in Candles: and of *Heraclides Ponticus*, who said that a Comet was a Cloud on high enlightened with light from above. *Seneca* in *Lib.* 7. *Nat. Quest. Cap.* 22. conceives that a Comet is no suddain Fire, but reckons it among the eternal works of nature. *viz.* the Stars. For he conceived there were more Planets than Fire, besides the Sun and Moon, but that the beginnings and endings of their motions were not yet known; seeing they finish their courses at vast distances of time.

Late Writers do also differ in this point. *Scaliger* herein consents with *Aristotle*, in thinking that a Comet is made of Elementary matter: buthe denies that it is inflamed. For in his 79 *Exercitation* thus he writes: *I conceive therefore that a Comet is a Vapor drawn by the force of some Star into the upper Region of the Air; the nature of which vapor is not burning, but of a mixt matter, like a fume or steam, receiving the Sun-beams, and therefore visible, and letting them through, and by that means tailed.* *Cardan* whom *Scaliger* there refutes, had said, That a Comet is a Globe in

the Heaven inlightened by the Sun, through which the Beams being transmitted, do make as it were a tail. Because the Heaven is ful of Stars, which are not very compact, but when the Air grows dry, or for some other causes, they receive and retain light.

Bodinus in his Theatre of Nature *Lib.* 7. *P.* 217. thinks it better ingeniously to confess his ignorance, than rashly to affirm any thing in this Point, or to assent to most light opinions. Yet he in *P.* 221. *of the said Book*, seems to be almost of opinion, that Comets are the minds of illustrious men, which having for innumerable Ages had a great stroke on Earth, at last being about to die they perform their concluding triumphs, or are recalled into the starry Heaven, there to be as it were bright Stars: and that therfore, famine, popular diseases, and civil wars do follow, as if Cities and Peoples were forsaken by those most excellent Captains and Governors, who did pacifie the offended Deity. Other late Writers, who teach that the Heaven is not solid, but a fluid body like the Air, hold that Comets are not generated below but above the Moon; some say of exhalations carried thither, others of a part of the Heaven condensed, and by that means shining.

And these are the chief opinions of Phylosophers about the nature of Comets: in so great a number whereof, 'tis doubtless hard to judg which is the truest; nor wil the nature of this work, nor my design of Brevity suffer me at large to examine them all. Yet that it may appear, what we conceive to be most probable; their opinion seems to us most agreeable to truth, who hold that *all Comets have been, and appeared in the Region of Heaven which is above the Moon*: and if any man will call them new Stars, we shall not oppose him. Now that their abode has been in the Æthereal and not in the Elementary Region, may be gathered, chiefly by the regularity of their motion, the paralaxe, which they have had less than the Moon, as also by their equal duration. For since it has been observed that Comets have often endured a long space, and for six months together, in the same Quantity, and have alwaies had a regular motion: this can no way be attributed to a body composed of exhalations. For al such kind of Meteors, are made after an irregular manner, as may among others be seen in the Clouds, in which there is nothing perpetual, lasting, or regular. And the reasons which are brought for the contrary opinion, are but weak; and later Authors, do not without cause, call in question the observations of the Ancients; seeing there is need of great diligence to observe the Parallaxes. But whether they are bred anew by natural Causes, or are miraculosly produced by God, or whether they were before out of sight, and now at last appear, it is no easie matter by sufficient reasons to determine.

Yet this one thing, I think fit to acquaint you with in this place, that even the Ancients also did take Comets to be Stars, which sometimes appear, and then again become invisible, as may be manifestly seen out of *Hermes Trismegistus in his B. de providentia & fato*, where he thus writes *There is another kind which they call Comets, which appear but for a time, and a while after become invisible neither setting, nor being dissolved, and others become evident Proclaimers of Universal Events.* Now those have their place under the Circle of the Sun. When therefore somwhat shal befall the world, then they appear. And having appeared a few daies returning again under the circle of the Sun they become invisible, having shewed themselves in the East.

They say that Comets signifie wars; because hot and dry exhalations, do breed yellow choler in the bodies of Men especially of Kings, which afterwards make men prone to more violent motions, wrath, brawlings and wars thereof proceeding. Yet verily these are too remote causes of wars; the Polititians can tel us of neerer causes than these. And if wars depend hereupon, there is no need of many consultations, touching the composing of wars; we must fly to the Physitians, who by giving choler-purging medicaments may take away al wars, and pluck up by the roots all the Causes of Wars, out of the Bodies of Kings and Princes. Moreover, experience shews, that Comets have appeared, which have not been followed by any such events. This is for certain, since the Appearance or the Generation of Comets in the Heaven, is very rare and unusual, that they do undoubtedly portend somwhat, if not peradventure as Causes, yet as signs appointed by God to denounce his wrath against sinful men: whose particular signification, is nevertheless known

only

only to God, and not reveal to any mortal Man. This indeed hath been found true by the Experience of all Ages.

Nunquam Spectatum impune Cometam.

Ne're did a Blazing Star appear, but a sad story follow'd. *An Hexameter verse*

And that after Comets great changes have happend in Enpires, so that *Lucan* rightly cal'd Comets, Kingdom changing Comets, and *Camerarius*, thus turned the old Latin verse into Greek; *Oudeis Cometes, Hostin ou cacon Pherei.*

But to what regions and Provinces they portend their bad tidings, 'tis scarse possible for a man to know, till the Event hath taught him.

Chap. 3. *Touching the Elements, in as much as being Simple Bodies, they with the Heavens, do make up the Bulk of this World.*

NOw the Bodies of the sublunary Region are two fold, simple and compound. The simple, are those which are called Elements, because the rest are made up of them. Now the term Element which the Greeks call *Stoicheion*, although it have sundry significations, yet it seems they may fitly be reduced to two principal ones, the one *General*, the other *special*. For generally it is taken for whatsoever is first in its kind and has nothing before it: in which sense 'tis defined by *Aristotle* in the 4. *Metaph. Ch.* 3. *That is called an Element, out of which first inexisting in the individual species, a thing is compounded into another species.* Moreover in a more special signification, Elements are the immediate principles of mixt Bodies, and thus are defined by *Aristotle* in his 3. *de Cælo. Ch.* 3. *t.* 31. The Element of Bodies is that into which the other Bodies are divided, wherein it is potentially or actually: but it self is not divisible into parts of sundry sorts. And in the signification we are hereafter to treat of Elements. *Element has a twofold signification.*

And these Elements truly have a *twofold* office and a double consideration. For their *first* office is, with the Heaven to make up this whol bulk of the world: and in this manner they are absolutely considered according to their essence, without any relation to mixt bodies: The *Second* is, to be the matter of mixt Bodies. And for the performance of both these Offices, peculiar qualities are given them by Nature. For that they might perform the *former*, they have heavines and lightnes: for the *latter*, heat and cold, moisture and dryness; whereby they can mutually work one upon another and make up a compound. Now the Elements are to be considered by us in this place, both waies. *Element in that latter sense have a twofold Office.*

Because the Elements do first perform that Office of theirs whereby they are carried to certain places in the world, and do therein naturally rest; we must first speak of their motion, and thence draw their Nature and number. The Elements are simple Bodies. For although, being considered as made up of matter and form, they may be termed compounds, yet in respect of mixt Bodies, they are called simple. For they are not made up of other Bodies which were before them, but themselves are the first Bodies of themselves existing in the world, of which all the other Bodies are compounded. Since therefore they are simple bodies, a simple motion is due to them. *The Elements are simple bodies and have a simple motion.*

Now there are *two* simple motions: the *Right* or *Streight*, and the *Circular*. The *Circular* belongs to Heaven: and therefore the *Streight* motion we attribute to the Elements, having therein experience to justifie what we do. For we see these Elements so called, and all things compounded of them, according to the Nature of the prevailing Element, go in a direct line to their proper place. Now direct motion is either *to the Middle*, or *from the Middle*; to the middle place of the world which as also the lowest, heavy things are carried; from the middle to the outmost part, *There are two simple motions.*

Why heavy things move downwards and light things upwards.

which is also the highest, light things are carried. For *light* things are such as being un-hindred do alwaies move upwards, and which alwaies swim at the top: and *heavy* things are those, which not hindred, are alwaies carried downward, and sink to the bottom of every thing. But what the cause is why some Bodies move downwards, others move upwards, we must now enquire, and see into the end and efficient cause of this motion.

The end of this motion.

As to the End, since Nature does nothing in vain, and all Natural things act for the sake of some good, we must not think the Elements are moved with certain motions to no purpose; but we must hold that every Element is carried to its own place, as to its perfection: whence *Aristotle* saies well 4. *de Cælo. c.* 3. *t.* 22. *For every thing to be carried to its place, is nothing else but for every thing to be carried to its own Form.* For the Forms of the Elements being of al others the lowest and most ignoble, and hardly able to defend themselves sufficiently from external injuries, their proper place is added to their form as an assistant to preserve the Body thereof, which as it were an external Form, supplies what is wanting to the internal Form. To its proper place, therefore, as to its own perfection, every Element is moved. And the perfection which they receive therein, is the preservation of their, Heat, Cold, Lightness, Heaviness, and consequently of their Form.

The Efficient Cause.

As to *the Efficient Cause of the motion of the Elements* Authors do many waies vary. Yet verily, if we shall rightly weigh the matter, and not wilfully intangle a a plain matter with difficulties, and rightly mind the sense of the question, it seems not so hard to answer thereunto. For if a man should ask, what is the efficient cause, that the Fire and Earth, actually existing by their forms, the former mounts right upwards, the letter moves downwards, unless they be by some other thing violently detained; we answer simply; that the Fire by its Form is moved from the middle of the world upwards, and the Earth by its form is moved to the Centre of the world downwards, for this motion is to them Natural and therfore it must also proceed from Nature, or an inward principle, which is their Form, and not from an outward. For this is proper to Natural things, to have in themselves the principle of their motion, as may be seen in the 2. *Physic. c.* 9. *t.* 48. Also the form of an Element which informes it, and is its Nature, is also the principle of its motion. Also to what hath been said may be added, that as *Aristotle* saies in 2. *Physic. c.* 3. *t.* 37. an effect actually existing, requires a cause actually existing; and that especially in effects, whose whole essence is in the present performance, as motion is: for the cause hereof being taken away, it is also taken away, nor can it ever be separated from its efficient cause. But the motion of the Elements is an effect actually existing. It requires therfore a cause actually existing; which can be no other then the Form. For this only alwaies actually exists with the motion: but those other causes which some do bring, as the Generator, the Remover of impediments, may be separated from motion, and while it is yet existing, they may either perish, or if they perish not, yet may they not coexist with the motion. Nor does what hath been formerly said of motion, hinder this opinion: that the Moveable is distinct from the mover; which seems not to agree to the motion of the Elements, if we hold their form to be their mover. For the Earth, when it is moved to the middle of the world, it is not moved, as having matter. For the matter in it self, is no more enclined to move upwards then downwards, but is indifferently capable of al motions; but as it hath a form, which determies and restraines the aptitude of the matter, to receive this form. And therefore seeing the matter is here the passive principle of the motion, it cannot be the active. And this doubt, truly, may be satisfied; if we distinguish betwixt an Agent with the transmutation of another thing, which is properly called an efficient, and requires alwaies a Patient different from it self: and betwixt an Agent only (as they say) by emanation of the effect, which does not by acting change another thing, but after the Nature whereof, the effect follows of its own accord, that as it were not acting; and such an agent is the Form in respect of al the accidents which are Naturally in the compound. For all accidents do of their own accord follow the form, without any motion or transmutation of the subject. That therefore which hath formerly been said concerning

the

the distinction betwixt the moveable and the mover, is true of an Agent by transmutation. But an Agent by emanation is not necessarily distinguished from the Patient. Howbeit, even in an immanent action, or which is produced only by emanation, we may observe some distinction of Agent and Patient. For the Form, as the form acts; and suffers as it is in the matter. And therefore, in the motion of the Elements, the form as the form, is the Efficient Cause of the motion; but as it is in the matter, it is moved with it. For the compound is moveable, or is the subject of motion, which is distinguished from the form, in respect of the matter. For the matter also, is really distinguished from the form, And this is the true explication of this Question, Dextrously propounded, which must be by no means confounded, with other questions which border thereupon. For it is quite another question; Why an Element actually existing by its form, not hindred by any thing, tends to its own proper place, the cause whereof hath been already expressed; from this, why for examples sake, water which of it self moves downwards, fire being put under, begins to mount up in vapors; or, what is the Cause that a Stone which hung in the Air fastened to a string, as soon as the string is cut fals downward. For the cause of the former is the admixture of Fiery and Aery particles, which attenuate the water, and carry it with themselves aloft. And the cause of the latter is clearly, that which removes the Impediment.

Why water ever the fire moves upwards?

The Elements therefore not being hindred, are moved by their forms, as the internal and immediate cause, as hath been shewed: which formes as all others, cannot be perceived by sense, but are by us known and described by heavines and lightnes as accidents. For it is an usual thing to describe the hidden forms of things, which want peculiar names, by their proper adjuncts, which are better known to us.

Moreover what may be the Cause, why the Elements are moved successively and leisurely, whether only because of the resistency of the Medium, or through some other cause, comes now to be enquired. Some late writers are indeed of opinion, that there is a twofold resistency, one external, which proceeds from a ful Medium, which is the Cause that motion is slower then it would be, if it were performed in an empty space, if such there were: another internal, which proceeds from the Nature of the moveable, resisting the mover. Howbeit the opinion of *Aristotle* and *Averrhoes* is truer, who hold, that *the Elements have only an external resistency in their motion, proceeding from the Medium*; (For it being ful and corpulent, resists the mover in its motion, according as it is more or less thick) but no internal. For if there were any internal resistency, it should proceed either from the Form or the Matter. Not from the Form: for, it being the mover, does not resist its self in its own motion, but endeavors as speedily as may be, to carry the moveable to its due place. Nor from the matter. For it being meerly passive, and indifferent to receive all motions, and having no power to act, can also be no cause of resistency. All the swiftnes therefore and slowness of the motion of Elements, depends upon the proportion of the Virtue and power of the mover, to the resistency of the Medium. For when the force of the mover is much greater, then the power of the Medium to resist, the motion is swift: but when the power of the mover does not much exceed the force of the Mediums resistency, there the motion is slower: but where the mover does not at al exceed the force which the Medium hath to resist, there is no motion at al. Howbeit what hath been said must be understood only of the Elements which are simple Bodies, and have an internal principle of their motion. For in things moved by external force, the case is otherwise for they by their proper Nature resist the mover, and according to the excess, whereby their power is overcome by the power of the mover, they are swiftly or slowly moved.

Why the Elements are moved leasurely and by degrees.

From what hath hitherto been said the Cause may easily be rendred; why heavy and light things do move more slowly at the beginning and swifter at the end. For experience shews that an heavy thing falling from an high place, smites more strongly where it lights, then it would have done falling from a lower place. For though divers men think differently in this point: yet must we resolve, that the true cause hereof, is the abatement of the resistancy of the Medium; and the abatement of the resistancy proceeds from the forgoing motion, which augments the swiftnes of the follwing motion. Now why the precedent motion augments the swiftnes of that which follows, and why it abates the resistency, the Cause is this.

Why heavy and light things are moved more slowly in the beginning, and more swiftly at the end?

Every

Every movable is swiftly and easily moved through a Medium, which is moved the same way with it; and less swiftly through a Medium that moves not; slowly through a Medium which resists the moveable, and bears the contrary way: an Argument whereof we have in sailing with or against tide. And therefore, when any heavy Body begins to tend downwards first the quiet Air resists it, the resistency whereof is nevertheless overcome by the heavy Body, and drives the next part of the Air downwards: this first part of the Air being driven, drives the second part of the Air, next unto it. And therefore when the heavy Body comes to this part, and finds it not resisting but going the same way and furthering it in its motion, it begins to be moved more swiftly: and the Body being thus more swiftly moved, will more vehemently force and drive the third part of the Air: and it being before driven also by the second part of the Air, wil be more swiftly moved then the second, and will more strongly bear down the fourth part. When therefore the heavy Body shall reach the third part of the Air, finding it more vehemently moved downwards then the second, it wil also be therein more swiftly moved; and so it will yet more forcibly bear down the fourth part, being before prest down by the third, and when it comes to it, it will be therein yet more swiftly moved, because of the lesser resistency and the Mediums being moved the same way. And this swiftness of the motion wil be for the same Reason continually augmented even to the End. But that no obscurity may remain, we must know, that *Heavineß and Lightneß are taken two manner of waies*, Either for the first act or quality, by which a thing hath a propension to move upwards or downwards; or for the second act or operation, and impulse, by which some bodies are moved upwards, others downwards. Which two things the School-men to distinguish, they called the former *Gravitatem*, the latter *Gravitationem*: and hence 'tis said that Gravity in the Elements cannot be augmented, but Gravitation may: also, that the Elements in their own places are *Gravia* and *Levia*, heavy and light indeed, but they do not *Gravitate* nor *Levitate*, that is they strive not to go upwards or downwards.

Heavineß and lightneß are understood two waies.

Now the next thing is, that we search into the *Number of the Elements*, about which later writers do wonderfully differ. *I shall prove that there are four in Number.* And to prove the same I shall not bring many reasons; seeing our very sences will easily shew us how many Elements there be. For we perceive the Water, Earth and Air which fills that vast space above the Globe of the Earth, nor is the force of Fire unknown to us. 'Tis here my mind only to produce one reason which many use. There are two direct motions, one from the middle, another to the middle. Therefore, for these two simple motions there must be two subjects which are simple Bodies, one which is absolutely heavy, which is called Earth; another, which is absolutely light, called Fire. Now because 'tis the wil of Nature that the world should be one; and two contrary extreams cannot make up one compound; she alwaies couples the extreams by things of a middle Nature, and knits the last of the upper kind, with the first of the lower. And therefore in this case, a Medium is requisite. But this cannot be one only. For if that were allowed, it would possess the middle place betwixt the extreams, and so it could not be capable of a direct motion. For neither should it be truly moved from the middle, nor to the middle, but it should be Capable of both these motions, and so could not be called heavy more then light. And therefore we must hold that there are two Mediums, the one of which is light and moves from the middle upwards, but is in some respect heavy; which is called Air; the other must be absolutely heavy, and tend to the middle, yet in some respect light; which is called Water. There are therefore four Elements: *Fire*, *Air*, *Water*, *Earth*. There cannot be a fift, for the same cause why there cannot be but one Medium. If any one will hold there are more then five, he will be confuted by sense and experience.

The number of the Elements.

A question there is, *Whether these Elements are found pure in the World*: To which question we thus answer: If the Elements are considered absolutely in that simplicity, which is due to their Nature, and whereby they are the Rule and standard of mixt Bodies, they are surely to be found any where pure. But if they be compared with mixt Bodies, and the question shal be; whether they exist also by themselves, out of mixed Bodies, it may be said they are found sincere and pure, not indeed with an absolute purity, of which we spake just now, but with such an one, as they are capable of, compared to mixt Bodies. Howbeit the extream are purer then the middlemore.

Whether the Elements are found in the world pure.

Middlemore. Nor do the Elements, though they are not found exactly pure, lose their Name, so as to be called mixt Bodies. For those Bodies are only to be termed mixt, wherein there is so great a departure from the Nature and purity of Elements, that the Name and Form being cast away; they come to be now some different thing from the Elements, and receive a new and peculiar Name of some sort of Natural Body. But wherever there is so great an excess of one Element, that it transcends al comparison, with the rest that are joyned with it, in *that* the Name of Element is retained. *Which are mixt Bodies?*

It now remains that we speak of the Elements in Particular, as much as the Nature of this work will bear. And to begin with Fire, though many late writers endeavor to cast it from the number of Natural things, and take special pains to prove that it does not exist under the concave of the Moon: yet shall we subscribe to the remarkable consent of the chief Phylosophers, to reason strong enough, and experience it self especially seeing the Arguments brought to the contrary do all in a manner tend to prove, that this fire of ours, is no pure fire; whence notwithstanding it follows not, that there is no pure fire, nor that it is any where to be found: nor though all the properties of our fire do not agree to that under the Moon, does it therefore follow, that it is no true fire; seeing most of those things which are vulgarly attributed to our Fire, do agree to Fire not of it self, but accidentally. *Whether there is any Elementary Fire?*

For there is a great difference betwixt this Fire of ours which we daily make use of, and pure Elementary fire. For our fire of the Kitchen is not pure, but mixed with vapors and gross matter, and therefore it shines, it burns, it wants fuel. But that there is pure Elementary fire under the Sphere of the Moon, the great lightness thereof, and its prepetual endeavor to ascend, does argue. For *it is of all Elements the most light and thin Body*, As next in place to Heaven, so in Nature most of kin thereto, unto which also, if forced therefrom, or generated elsewhere, it tends as to its proper place, concerning which matter *Scaliger* in his 9. *Exercitation* thus writes. *The Smoak which ascends, hath very much fire in it. For it ascends not because of water: much less because of the Earth. Nor does that motion proceed from the Air; for it is already in the Air. What place therefore does it seek? That place verily which above the Air is due to the lightest of Bodies. And again, these are the principles of that demonstration whereby 'tis proved, that the Element of Fire is under the Sphere of the Moon,* viz. *Bodies Natural, Motion, Place. Of these are propositions certain, True, Primitive, immediate, thus made, the Causes of this Conclusion: that the place of Fire is in the upper space under the Moon, above the Air. Every movable thing is a Body: all Fire is movable,* Ergo. *Other two: Every body is in a place; all Fire is a Body,* Ergo. *Thirdly, as many more; Every movable moves Naturally to its own space; Fire is a Body movable,* Ergo. *And the two last, which knock the Nail to the Head. Every space to which a Body Naturally moves, is the proper space of that Body; The Fire moves Naturally upwards,* Ergo *the space above, is proper to the Fire.* *How Elementary Fire and Kitchen fire differ.* *Fire the lightest Element.*

The exceeding lightness of the Fire is attended by exceeding rarity, and it hath least matter of al the Elements, and amongst natural things, it comes nearest the Nature of Form; and therefore it hath the greatest activity of al the Elements. Yet, when it is pure, and of it self, it does not burn: but that our Fire burns the Cause is; in that it is condensed, and sticks in gross matter, whence its parts being condensed and brought into a narrow compass, attain the greater force. Or as *Scaliger* saies *in his* 2. *Exercitation, S.* 2. it hath the power of burning from the propinquity, Multitude, Cohesion, Coagmentation and union of its parts. An argument whereof we have in a red hot Iron, wherein the force of the Fire is greater, because of the condensation of parts, then it is stubble which consists of more spungy matter. The same appears if you set spirit of Wine on Fire, for you may draw your finger through the same without hurt, as also through the upper part of the flame; which in a red hot iron you cannot do. The said Elementary Fire is not of it self visible, no more than the Air, nor does it shine, unless it be received in a thick matter. *Why our Kitchinfire Burns?*

No found Phylosopher denies that the Fire does belong to the Elements, which make up this world and constitute mixt Bodies. For although *Cardan* hath endeavored to exclude the same from the number of Elements; yet is he well confuted *Fire is an Element.*

by

by *Julius Cæsar Scaliger* in his 9. *Exercitation.* For seeing, as he also teaches, in his 10. *Exercitation*, that heat which is a most manifest and effectual Quality, is accidentally in many things, there must of necessity be some first subject, wherein it is primarily and essentially: For nothing is in any thing accidentally, which is not essentially in some other thing, primarily and of it self. And truly, the first subject of heat is Fire, at first created by God with the other Elements, and furnished with its qualities. And there was never any time when Fire had not those qualities flowing from the Form thereof. But from the ignorance of the Creation of the world came, that Opinion of *Aristotle*, which he hath in the 1. *Meteorol. cap.* 3. where he saies: *Seeing the first Element is moved Circularly, the Bodies which are therein, alwaies that which is neerest at hand, being severed by the motion of the lower world and Body, is inflamed and causes heat. For thus we must understand the matter from the beginning. That Body which is under the upper Circumduction, being it is as it were a kind of matter, and potentially hot and cold, and dry and moist, and whatever other adjuncts follow these; such it becomes, and arises from motion and Immobility.* An absurd saying, truly, and unbecoming so great a Phylosopher! For what matter I pray you can we imagine actually existing of it self, which is potentially Hot, Cold, Moist, Dry, but actually receives these qualities from Heaven? For although some that they might stick by *Aristotle*, have fancied a twofold heat in Fire, one Natural, which follows the proper form of Fire; the other adventitious, which the Fire receives from the motion of Heaven; yet *Zabarella* in his 1. *B. de qual. prim. c.* 8. writes well, that the words of *Aristotle* do not receive all this Interpretation; for *Aristotle* saies, that all this matter of the lower world is potentially Hot, Cold, Moist, Dry, but is made actually so by motion and immobility. Therefore he allows no heat to the Elements, besides what they receive from the motion of Heaven. Yet he himself fals into a much more absurd opinion when he writes in *the following Chapter*: thus, *If any Man shall aske whether the first qualities are sooner or later then the Forms of the Elements, we must say, they are fore more and later in several respects. For in Original and according to the order of Generation, they are doubtless sooner, as the previous dispositions are in generation before the substantial Form, to the eduction whereof they are directed, but they are Naturally after the same, in as much as they are accidents. For accidents are after their substances. And in as much as they are Effects, but the Forms causes, I do not mean efficient causes but final. For qualities are produced in the matter, for the sake of substantial Forms, and are directed to them as to their End, as also they are conserved in the Elements by Heaven, that the Elements themselves might be conserved; so that the next final cause of these Qualities, is the Constitution of the Elements; but the remote and ultimate, is the production of mixt Bodies. For the Elements are made for the mixt Bodies, and to be their matter. Thus therefore Qualities may be said to follow the Forms of the Elements, in as much as the Forms are their final causes: but the qualities themselves, although they are preparations for the Eduction of Forms, they may not therefore be called the Causes of the Forms, but only the latter Effects; seeing accidents are Naturally later then substances. And therefore while they are together in the Elements, as Naturally conjoyned and substantial Forms and proper qualities; yet the Forms are in the first place, and the qualities afterwards, and so they are said to follow the Forms of the Elements; especially seeing, as we said before, they are given to the Elements by Heaven, for the Eduction and preservation of their Forms.* For if heat be a disposition previous to the reception of the form of Fire, into what matter I pray you is that disposition introduced, and in what matter is the Heat inherent, before the Form of Fire comes. And will the Form of Fire be idle, will it shed forth no quality? Thus one absurdity being gathered infinite do follow.

And the first subject of heat.

Not only potentially hot as Aristotle would have it.

Now the Fire of it self, is a substance most subtil, and thin, piercing through al things; which neither shines, nor is seen whilest it is pure and simple without any mixture. But when it is mixt with and is inherent in other things, it makes our vulgar Kitchin Fire, which differs not Essentially from the pure Element of Fire, but herein only in that it is mixed with some Heterogeneal matter.

It is a substance.

Thomas Fienus, indeed, in his *Apology* against *Sanctacruze*, *p.* 50. holds that this Fire of ours which we use, is only an accident. But the Reasons of that opinion are refuted in my 3. *Hypomne. Phys. Ch.* 1.

Not an accident.

And

And since this Kitchin Fire of ours, is useful to many intents and purposes, many authors write many things touching the Inventors thereof, as may be seen in *Plinies Natural History, B.4. Ch.* 12. and *Book* 6. *Ch.* 30. *in Vitruvius Book* 2. *Ch.* 1. But it is apparent by the sacrifices and by the story of *Tubal-Cain*, that the use thereof was known to the first Fathers of the world. Though it is not to be denied, but that the other uses thereof were later known to other Nations; and new inventions are alwaies added; as may be seen in Gun-powder, and sundry sorts of Fireworks, made thereof. *The inventors of Kitchin Fire.*

Now what the difference is betwixt Fire as it is potentially in mixt Bodies, and as it is actually hot, is not easie to explain, yet a thing necessary to be known. For Sulphur to feel to is as cold as a cold stick that hath no Brimstone in it; and a piece of Willow Wood dried is not colder to feel to then a piece of Pitch-Tree Wood. And spirit of Wine which contains much Fire in it, in coldness to feel to, is not inferior to the Wine it self. Yea in a flame which actually is hot, there is less quantity of Fire and of the smal particles thereof, then in Brimstone; since in Brimstone not set on Fire, that is united in a smal space, which is diffused in a great flame. In Gun-powder a mighty Quantity of Fiery Atomes lie hid, which is nevertheless cold to feel to. But the flame of the said Gun power, when it is set on Fire, burns exceedingly, though the Atomes are severed. This therefore is to be explained, why in a mixt body potentially hot, so many fiery Atomes contained and collected, do produce no actual heat; or, what it is that causes the Fire to heat. *'Tis either Potential, or Actual.*

The Former happens, because the Fire is mixt with other things, and is contained quiet under the dominion of a superior Form. But it heats actually, when it is separated from the rest of the Bodies, wherewith it was mixed, and being set at liberty, freely acts. Of which latter we shall now speak. *What makes the fire not to heat or to heat.*

But actual Fire is variously disposed. For if it be pure, it neither shines nor is seen. Of which *Scaliger* in his 9. *Exercitation. Meat roasted on Spits is not touched by the Fire we see, but it is touched by the Fire we see not: and it is so touched, sometimes, as to be burnt to a Coal.* In like manner, if a man hold his Hand over the flame, so that the flame do not touch it, yet his Haud wil burn. Fire also is perceived in quick Lime, when water is poured thereon, in dung when it rots, in Water, Oyl, Stones, Metals, which are heated. *Pure fire neither shines nor is seen.*

Now Fire appears to the sight and not only to the touch, two manner of waies; either in an hot Coal or Flame, as *Theophrastus* teaches in his *Book de Igne*, Now by a Coal is understood any Body red hot, that affords no flame. *It becomes visible two waies.*

But that we may rightly understand, what Flame and Inflamation is, we must of necessity presuppose some Principles. *Touching flame and Inflamation.*

The First is: That there is Fire in all Bodies, and that so as to retain its perfect Form, as I have demonstrated in *Hypomnem. Phys.* 3. Howbeit it is in a greater quantity in some Bodies in a lesser quantity in others. *Axioms.* 1.

The Second is: That actual Fire is alwaies Naturally moved. And whereas it is not so in mixed Bodies, the reason is, because it is contained quietly with other things in the compound under the dominion of an higher Form. For the Forms are the bands of things. 2.

The Third is: Fire is two manner of waies in compounds, the one as fixed, in Salts and other things not inflamable, nor combustible; the other, as volatile, so that by means thereof, the Body in which it is, may be inflamed; after which manner it is in Sulphur and al Bodies that partake of Sulphur. Upon which account, those Bodies which have Fire good store in them, are easily burnt by Fire, which, as *Scaliger* in his 9. *Exercitation*, speaks, *Gives back ashes to the Earth moisture to the water, and takes and keeps to it self, that which is invisible to vulgar Eyes, but cannot conceal it self from the Minds of wise men.* 3.

The Fourth is: That there is a Consent of Natural things, and things like are drawn to like. But contrary things Fly from one another *Ex Hyponem. Phys.* 1. *cap.* 1. 4.

The Fift is: That Fire hath a great similitude and likeness to things that are apt to flame; because they consist of Fire for the most part, and Fire does easily unite it self to them. 5.

The actuation of fire what it is. Hence we conclude, that the Actuation or actual breaking out of Fire, is the separation of that Fire which is potentially in mixt Bodies, from other things mixed therewith. I say potentially, not in respect of the First act, or the Form of Fire, which it hath really in the mixt Body, but in respect of the second act and operation thereof.

The manners thereof Which separation is made divers waies, as was said before, with flame, and without flame. Without flame in putrefaction, quick Lime, hot Coals; with flame, when Bodies are set on a flaming Fire.

What inflamation is. Of which to speak somwhat in particular, we say: that inflamation or setting on a flame, is, the breaking out of Fire from a Body apt to flame, and containing a Sulphureous Exhalation, caused by the touch of Fire near applied. For when Fire already actuated, does touch a body inflamable, the Fire therein, is attracted by the external fire, and by reason of similitude, moves of its own accord thereto, and unites it self therewith.

What flame is. Now flame is Fire breaking out of an inflamable Body, touched by actual fire, and sticking in the fume, as in a Sulphureous Exhalation, and shining therein, and moved therewith. And therefore *Aristotle* in 1 *Meteor. Ch.* 4. defines flame to be the *Boyling out of dry Fire* and in the 4. *Meteoral. Cap.* 9. *Burning Smoak.* For flame is Fire, but not pure, joyned with a Dry and inflamable exhalation. And when it is set on fire, the fire extends much farther then the flame. And therefore, as hath been said, meat roasted on spits, is touched indeed by the fire, but not by the flame, and a mans hand held above the flame, may be burned, and paper or a candle may be lighted also above the flame. Howbeit fire is then only seen, where being in a great quantity, hath a certain Fuliginous matter arising from the fewel, joyned therewith.

Actual fire is bred two waies Now actual Fire is ingendred, and at last breaks into flame, either by propagation, or by Coition, and union. The first is caused, when actual fire manifest to the sences, does touch another inflamable body, and sets it on fire, drawing out the fire which lay hid therein. The second is, when fire which lies secretly hid in mixt Bodies, is drawn out, without the contract of external fire, and being united does actually and manifestly shew it self.

The first manner is most common, when actual fire does set on fire other inflamable Bodies. For by reason of affinity, it is easily united to them, and draws out and unites to it self the fire in them. *Galen* in his *B. de usu respirat.* calls that same inflamable Body *the Root of Fire:* and *Theophrastus* in his *B. de Igne* termes it *the Beginning of Fire.*

Things which have sincere sulphur in them, easily inflamed. And because all things, are inflamed and kindled by means of Sulphur; those things that have sincere unmixt Sulphur in them; or though they have little thereof in them; yet are so disposed, that fire may easily insinuate it self into all their parts; such things I say are easily set on fire. For in the first place, if the Sulphur by much and pure, and not mixed in its smal parts with other things, but is of it self alone immediately obvious to the external fire, it is easily united thereto, because of its similitude: Contrarily such Bodies as have their Sulphur, though much in Quantity, mingled in its smal parts with other things, are not easily inflamed. Whence it happens that Pitch Wood is more easily kindled then Oak wood, though 'tis a question whether there be more Fire in Pitch wood then in Oak. For in the Former, the fiery Sulphureous parts are unmixt and at hand; but in the latter the inflamable fiery parts lie deep, yet are they discovered by their effects in warming of a Stove. By reason of plenty of unmixt Sulphur, spirit of Wine does soon take flame, and the purer it is and more separated from the Flegm, the sooner it is set on fire. But this is seen most of all in Bitumen, which is exceeding Sulphureous, and containes in it a spirituous matter, of kin to fire, and therefore is soon lighted, and conceives flame even far from the Fire, as *Pliny* in *Lib.* 2. *C.* 105. saies, Fire leaps to it wherever it sees it. And After this manner they say *Medea* set *Jasons* Concubine on Fire, as *Pliny* writes *in the same place.* For when *Medea* had given to *Creusa* a Crown or Garland smeared with Bitumen, and perswaded her to be present at the sacrifices, the Garland smeard with Bitumen, took flame from the Fire and lighted wood, and so burnt *Creusa.* And I remember, when I was making Balsam of Sulphur, and had put into a Glass Receiver, flower of Brimstone, spirit of Terpentine

and

and ſpirit of Wine, that they might ſtand in digeſtion, and left it to the care of a certain Student, to cover the mouth of the Receiver with a Glaſs Cover and cloſe it up with ſpaniſh wax; ſome of the ſpaniſh wax being lighted and falling upon the lid, the Spirit in the Receiver was ſet on flame, although it was hardly a ſixt part ful. Hereunto belong common Brimſtone, Gun-powder, Pitch, Aſphaltum, Ambar: Hence *Galen* relates in his 3. *de Temperam Chap.* 2. that a man in his daies, made a great boaſt of lighting a Candle after a wonderful manner, which he firſt put out & then applied it to a wal to light it, which he made ſhew to be done without Fire, which though ſome thought it to be a magical operation; yet when it was known, that the ſaid wall was ſmeared with Brimſtone and liquid bitumen, the wonder ceaſed. Like hereunto, is that which *Cardan* relates in his tenth Book *de Varietate Rerum*, of a certain man who would light Candles not perfectly extinguiſhed at the mouth of a certain Image, which was made on purpoſe and daubed with Sulphur and Bitumen or Petroleum, that ſo the Image might ſeem to vomit Fire.

Why dry bodies are eaſieſt inflamed.

Moreover, Bodies ſpungy and dry, though they have little ſulphur in them, yet becauſe they are dry, and the watry parts, which otherwiſe do moſt of all hinder kindling into a Flame, are abſent, the Fire eaſily unites it ſelf to the ſulphur which is in them, whence they come to kindle. Such bodies are, dry Wood, Torches, Straw, Stubble, dry Hay, Tow, Wool, Paper, Tutch-wood, Links.

Why viſcous and watry bodies are hard to take fire.

But that ſome things, as Oyl, Suet, Wax, which contain ſtore of Sulphur in them, are not eaſily ſet on fire, but need ſtore of fire to light them, as when they are boyling, or muſt have a wiek to cauſe them burn: the reaſon is, becauſe thoſe bodies are viſcous and clammy, and not ſpungy, and becauſe they ſtick together in their ſmal parts. Alſo, becauſe they have a watry Subſtance, mixed with their ſmalleſt parts. And the mixture of watry parts, does moſt of all hinder Inflamation. For Water as much as any thing hinders the breaking out of flame.

For ſeeing Water mingled with Wood, only by the roots thereof, does render them leſs ſubject to take fire, much more wil that Water do it, which is moſt intimately mixt with the ſulpur. But if a dry wiek be added to Oyl, Suet, or Wax; the flame or actual fire in the wiek, draws to it ſelf its cozen fire mixt in the matter cloſe by, but ſlowly, becauſe it cannot do it plentifully. For that ſame watrineſs hinders, which muſt firſt be removed, that the ſulphureous part may be lighted. Now this is ſlowly diſpelled: which alſo while it is in doing, the fire alſo flies away, and ſo it needs new to ſucceed it, which it does becauſe it is freed from the Water. And indeed in every body which feeds fire ſlowly, there is ſomwhat which reſiſts fire. For otherwiſe there were no reaſon, why the fire ſhould not be altogether ſuddenly inflamed, as it happens in Tow or Straw. And Brimſtone it ſelf affords a manifeſt example hereof, which does indeed ſoon take fire, and yet is long before it burn out, becauſe it has in it ſtore of acid ſpirit, which hinders the Inflamation.

Now the flame which we ſee kindled in any matter, is not alwaies the ſame; ſeeing the fire is in continual motion and flies away, a new fire comes freſh and freſh out of the thing burning. And therefore as *Ariſtotle* ſaies, *Meteor* 2. *The flame never continues the ſame.*

How the Fire is fed.

And whereas it is commonly ſaid that ſulphureous things, and whatever wil kindle, is the food of fire; *that* muſt be rightly underſtood. For it is not ſimply true, becauſe fire is a ſimple body, which properly is not nouriſhed. But in that the fire cleaves to the body inflamed, it is not becauſe it needs food, but becauſe through ſimilitude, it endeavors to draw out the fire lying hid in the body inflamed, and to unite it to ſelf, and ſo to multiply it ſelf. For every Nature deſires to multiply it ſelf, and there is in every thing an appetite of Infinity and Eternity, as *I. C. Scaliger* ſaies *in his 9. Exercit.* which is chiefly effected by union with its like. And therefore fire ſticks ſo long at leaſt to the body inflamed, as there is ſulphur and fire therein, which failing, it flies away.

The difference betwixt burning things that flame and thoſe that do not flame.

Alſo from the Premiſes the difference appears between a flame, and burning coals or other things which yeild no flame. Flame, as has been ſaid, is joyned with fuliginous vapors, and there is more fuliginous matter in a flame than in coals. For when the char-coals were made, the greateſt part of the fuliginous matter flew away. And becauſe abundance of fuliginous matter does choak the flame, yea and the fire it ſelf, and hinders the ſudden propagation thereof, of neceſſity the fuliginous vapor muſt have egreſs, whence it comes often to paſs that fire lies hid in a

close chamber, but flame arises not therefrom. But as soon as the door or window is opened, and a passage is given to the sooty vapors, it breaks forth into a flame. And because the coals themselves have yet in them some fuliginous matter, the fire consumes the coals no faster, than the fuliginous vapors can find egress. And therefore thongh the whol furnaces of Chymists are at once filled full of coals, the fire consumes no more of the coals, than is answerable to the egress of the fuliginous vapors, and so by opening or shutting, more or fewer, greater or smaller vent-holes, a man may moderate the fire as he pleases. For no more fire is kindled than the Prohibiter wil allow. Yea and coals may be so set on fire as that they shall not consume after this manner. Take a strong pipkin or stone pot, which will endure the fire, fil it with coals, and put on the cover and lute it round about, and when the lute is dry, put the pot into the mid'st of a fire, that the whol pot may be red hot; and then the coals wil be all on fire (and if any wil not beleeve it, he may by breaking the pot be sure of it) which being done, suffer the pot being taken out of the fire to grow cold of it self, then open or break the pot, and you shal find all your coals whol. The cause whereof is because as the fire entred in through the pot sides, so it goes out the same way, but the substance of the coals cannot pass the pot sides.

What fire needs a free Air, what not.

Howbeit we must here observe that it is not common to all fire, nor does it agree to fire as fire to be extinguished in a close place. For its known by Histories, that there have been lights which have burnt long ina close vessel: but this is the property of some sort of fire only, namely of that which comes out of a mixt sulphureous body, as Wood or the like, with fumes and exhalations. For the flame only which arises from such bodies, being shut up is extinguished. For since in a continual flame there is a resolution of mixt bodies, and the mixt body is resolved into other things whereof it was compounded, and a body resolved requires a larger space, than that which is close compacted, it happens, because there is no place for the fuliginous vapors which steam out, part oppresses part; and because naturally there is no penetration of dimensions, while the compound is hindred from being resolved or loosened, the cause also of the dissolution is stopped, which is the actual fire.

And all these things which we have said, appertain to the first manner of generation of Fire, *viz.* when actual Fire is applied to a combustible Body, and a combustible or inflamable body is kindled by Fire put to it.

The sundry uses of this fire.

By this manner of Fire many things are made and prepared for the use of man: and hence come not only the melting and never breaking Fires of Chymists and other Artists, and those which are used in Kitchins, Stoves and Chambers to warm us; but also Candles, Torches, Links and Lamps. Candles, Links and Torches are made of Tallow, Wax, Pitch, Rosin, with wieks of Cotton and Cordage. Lamps are made of Oyl with Cotton, in a Glass or other Vessel. They are made to give light in dark places. Oyl of Olives, Line-seed, Rape-seed, Hemp seed, are vulgarly used; also Lamps may be maintained with spirit of Wine or other spirits. Now that which primarily and principally burns, is the Oyl or other inflamable liquor, which the wiek draws, which is hereby apparent, in that there are some snufts that wil not consume with Fire, such as those made of the Wood Asbestum, of which *Pliny* speaks in *his B. 19. ch. 1. and 2. and Book 36. ch. 19.* and of the stone Amiantos, of which *Dioscorides* speaks in his 5. *B. ch.* 147. as also of *alumen plumosum.* But if the wiek be combustible, it is secondarily both inflamed and burnt up.

Lamps burning in water.

And although Water do quench Fire, yet Lamps may be made, which burn in Water and are extinguished in Oyl; if namely the Wiek be soaked in liquid Vernish, and put into Water and so lighted: for then it wil burn in the Water; but if Oyl be powred to it instead of Water, 'twil go out.

Durable Lamps.

And that the Oyl may burn the longer, certain metallick substances must be mixed therewith. So if you take one pound of red Lead, half a pound of Ceruss, four ounces of quick Sulphur, common Oyl two pound, and mix them all in a Mortar by the Fire side, leisurely stirring it sometimes, and then digest them Eight daies in a Glass retort, and at last distil them, you wil have an Oyl which wil last a long time in Lamps. Or thus: Take Liturige one pound, live Brimstone four ounces, Loadstone one ounce. Let al being poudred be incorporated with two pints of Oyl Olive.

live. Let this mixture digeſt ten daies together; and let it be ſtirred about once a day, afterwards diſtil it with a retort, and uſe the Oyl for a Lamp. If you would uſe ſpirit of Wine for a Lamp, to make it laſt long, pour it upon equal parts of unſlak't Lime, crude Tartar, and Brimſtone, and diſtill it once through a retort. Or pour ſpirit of Wine upon equal parts of unſlak'd Lime, crude Tartar, and common Salt, and ſo diſtil it. Concerning the Lamp of *Ammon* ſee *Plutarch* in his Treatiſe *De defectu oraculorum.* Alſo *Cardan* deſcribes perpetual Lamps in his 10. *de Rerum Varietate* and in his 1 *de Subtil. de principiis rernm, Caput* 10.

And ſo much touching the firſt manner of the Generation of Fire, to which if any man wil refer that alſo, which is cauſed by the Sun's beams, I ſhal not quarrel with him. For if the beams of the Sun be ſo collected in a burning Glaſs artificially made to that end, that meeting in a point, they ſet on fire a combuſtible body, they do the ſame thing that fire applied does. *Hitherto belongs the propogation of fire by the Sun-beams.*

Moreover, There are alſo other waies, by which the fire which is potentially in a mixt body (that is to ſay, which actually and according to the form, is really in mixt bodies, but is not liable to the ſences, but lurks inviſible) may be called out of the ſaid mixt body, ſo as to become manifeſt to the Sences. *Seneca* in his 2 *B. of Nat. Queſt. num.* 22. writes, That Fire may be made two waies, one way is if it be forced out, as from the ſtriking of a Flint; another by rubbing, as when two Sticks are rubbed together a long time. But indeed there are more waies, and at leaſt three. For Fire is made. 1. By putrefaction. 2. By the flight of the Contrary. 3. By motion: to which ſome ad a fourth mentioned by us in the firſt, *viz.* the Sun-beams. *Or by Coition and Union.* *Which is done many waies.*

In the firſt place, ſince in Putrefaction the Heat and fire which lurk in the mixt body exhales, and thereby become united, by putrefaction, Fire is ſomtimes kindled. And it is known to Country-men, how hot an heap of dung wil grow, ſo that the ſtraw therein wil be quite burn'd. So they relate out of *Theophraſtus*, that a Ship laden with moiſt Cloaths, conceived Fire and was burnt up. Nor is it unknown that heaps and Stacks of moiſt Hay and Corn have been burnt up. Howbeit in matter putrifying hardly can there be ſo great an heat raiſed, that the matter ſhould flame, unleſs it gather ſtrength elſwhere. An example whereof *Galen* has in his 3. *de Temperam Cap.* 2. where he writes: that Pigeons dung was caſt neer the window of an houſe in *Myſia*, in the middle of a moſt hot Summer. The dung therefore putrifying, and being heated by the Sun, ſent forth a fiery vapor, which ſet on Fire the boards of the Window which were ſmeared with Rozin, and at laſt burnt the whol Houſe. 1 *By putrefaction.*

Secondly, Fire is collected and kindled by flight of its contrary; a manifeſt example whereof we have in Quick Lime, upon which if water be poured it grows ſo hot, that it has been ſeen ſet wood on Fire that has been by it: which comes to paſs, becauſe the fiery atomes or ſmal particles of Fire which lie hidden in the Lime, whiles they fly from the Water contrary to their nature, come to be united together, and ſo to operate. Howbeit there is a diſſent amongſt Authors touching the Reaſon of this growing hot of Lime when Water is poured upon it. *Theophraſtus* in his Book *de Igne*, writes thus thereof: *Seeing Heat is not without moiſture or exhalation, therefore Lime burns when Water is put to it, rather than alone.* He ſeems to think, that Fire lies hid in the Lime, but that it is not pierced without matter; but Water being poured upon it, it is brought into act, and exhales with the vapor, and ſo affects the touch. *Petrus Aponenſis* conceivs the Cauſe to be, that the Heat being kept in by Antiperiſtaſis of the cold Water becomes more forcible. *Jul. Cæſ. Scaliger* in his 5. Exercitation Sect 9. thus writes: *In the paſſages of the Lime, the natural moiſture being conſumed, there lurks Fire: which flying from the Ingreſs of the Water, and thruſting it ſelf into the ſolid parts, it collects it ſelf, and becomes ſharpened by condenſation: for the piece of Lime, whoſe half only is covered with Water, as far as it is out of the Water grows hot, receiving into ſelf that Heat which is baniſht out of the other parts.* The Comentator upon *Theophraſtus*, *de Igne* blames *Scaliger*, becauſe in the Lime it does not ſo fall out that one part receives the Water, another part the Fire. For the Water ſoaks through, and every where fils all the paſſages, nor can this Collection and denſation of the Fire be made in the inner part of the Lime as in a Tower of Refuge. 2 *By flight of the Contrary.* *Why Lime grows hot when waiis powred upon it.* *Theophraſtus.* *Pet. Aponenſis.* *J. C. Scaliger.* *The Commentator upon Theophraſtus.*

And

They are examined. And in good deed, true it is, that ſome humor exhales out of the Lime, with the Fire. But thus a cauſe is not ſhewed, why at laſt the fire begins to exhale with the Water, and why in other hot Bodies, water poured on does not produce the ſame effect. Nor hath the Antiperiſtaſis of *Petrus Aponenſis* any place here, ſince experience teſtifies that the heat is rather poured out, then that it gathers it ſelf inwards. So alſo there is no ſuch Concentration of the Fire as *Scaliger* imagines; for as ſoon as ever the Water is poured on, it pierces into all parts of the Lime.

The Authors opinion. I conceive therefore that the opinion firſt propounded is the trueſt. Namely, In the Lime there are many atomes of Fire, not ſo much they, which the violence of the fire could not draw out, as thoſe which have inſinuated themſelves during the long time of its burning in the Kil. For Chalk is of a Spungy Body. Therefore water being poured on, it penetrates into all parts of the Lime, which the fire avoiding, as contrary thereunto, it exhales, and ſo becomes ſenſible. And becauſe the Lime contains yet ſome moiſture in it, whereby it hangs together, that unites it ſelf to the water poured on, and leaves the Body, whereupon the Body of the chalk is diſſolved and reduced to pouder.

Mixtures made to burn with water or ſpittle. Upon this Ground, mixtures are made which are ſet on fire, being wet with water, Yea, or with Spittle: *viz.* If a like Quantity of Ship-Pitch, Greek Pitch, Sulphur, Tartar, Niter and Petroleum be mingled together, and double the weight of all in unſlak't Lime, be added, and all made up with the Yolks of Eggs, and ſome daies digeſted in Horſe Dung or in *Balneo*. This mixture is ſet on fire by Rain or any other moiſture. The like mixture may be made of Unſlak't Lime, Sulphur, a little Gum Arabick, and Line-ſeed Oyl: whereof bals being made, they wil be ſet on fire by Water thrown on them. So, if you fill an Egg-ſhell half ful of unſlak't Lime, and put Gum-powder on the top and ſtop the hole with wax: Then the ſaid maſs Thrown into cold Water, will be ſet on Fire.

3. *By motion.* Thirdly, Fire may be raiſed by motion: which comes to paſs, by the mutual rubbing together of two Bodies, which have Fire in them. For by rubbing and motion, the Fire which did lie ſtil in mixt Bodies, kept in bondage by an higher form, and throughly mixt with contrary things, is moved, and ſo gains motion and activity. And this betides more eaſily, if on woods now a while rub'd one upon another, Gun-powder, or Powder of Brim-ſtone or ſuch like be ſtrewed. So *Pliny* in his 16. *B. Ch.* 4. writes that *the Mulberry Tree, the Bay-Tree, and the Ivy and all Trees out of which Fire is gained, are hot Trees. Spies in Camps and Shep-herds have found this Experiment, becauſe they have not alwaies a Flint at Hand to ſtrik Fire. They Rub therefore one piece of Wood againſt another, whence Fire ariſes, which is received on tinder, a dry Muſhrom or withered leaves of Trees. But nothing excels Ivy which muſt be rubbed with Bay, or let the Bay Wood be rubbed with the Ivy. Alſo the wild Vine is approved in this caſe, not that which is cal'd Labruſca, but another ſort, which Climbes Trees like Ivy.*

4. *By the Sun beams.* Fourthly, Some refer hither the manner whereby Fire is kindled by the Sun-beams, of which we ſpeak above, in the firſt manner of gaining Fire. Whereof we allow every Man to Judg as he pleaſes. The thing is of it ſelf manifeſt and wel known, that by burning Glaſſes and other Glaſſes, Wood, Paper and other dry things are ſet on fire. With ſuch kind of Glaſſes *Archimedes* ſet on Fire the Enemies Gallies and burnt them up. Of which ſee what the Teachers of Opticks ſay, and *Johannes Baptiſta Porta*. Yea, and the Raies of the Sun may kindle fire without any Glaſſes, and experience hath ſhewed, that woods and bituminous Lands and Seas, have been accidentally ſet on Fire by the Sun's Beams.

Scaligar, refers to the Head the manner by attenuation of the Air: but he is confuted. *J. C. Scaliger* in the ſame *Exercitation, Sect.* 1. hath yet another manner of the generation of Fire, and conceives it may be made out of attenuated Air; where thus he writes: *We muſt confeſs that out of the Air moved, ſmitten and attenuated heat may be cauſed. Which if it proceed it turns to the ſubſtance of Fire, and that by Reaſon of the attenuation of parts.* But that this is falſ, does thus appear, that Stones and the hardeſt Bodies ſmitten together, do not cauſe any ſparkles of Fire, unleſs they have ſtore of Sulphur in them. And the Sulphur which is forced out of flints may be perceived by its ſmel. Moreover the Air cannot be inflamed, either by rubbing or any other way, but this is the property only of mixt Sulphureous Bodies. And if the Air it ſelf could be ſet on Fire, this lower Region of the Air had been long a go burnt

burnt up, at the burning of great woods and Cities. *Aristotle* truly, in his 2 *de Cælo, Ch.* 7. *Text* 42. and 1. *Meteor, Text* 3. Writes that the Air being moved is set on fire, and that arrows by motion grow so hot, that the Leaden points have melted. But I do not believe the truth of such reports. And if the Leaden points of darts could melt, much more should bullets grow hot, that are shot out of Guns, which they do not. And *Pareus*, in his *Apologismus Primus* saies that bullets shot against an hard Stone have been presently taken up without hurting a Mans Hand. And if Leaden points of darts or Leaden bullets, did grow hot with motion, much more would wax grow hot; and yet experience hath taught us that a bullet made of wax shot out of a Gun hath not melted, but hath gone through a boord two fingers thick.

Whether the points of darts do melt.

So much for the manners of the generation of Fire. Contraiwise Fire goes out, especially flame, when either the inflamable matter fails, or though it be present, it is hindred from flaming, and the Fire not suffered to come out of the mixt Body.

Contrariwise, Fire goes out.

For in the first place, when the inflamable Body fails, the flame ceases, when all the Sulphur which was in the Body is consumed. So when Tallow, Wax, or Oyl fail, the flame dies in the Wiek and Lamp; and when the wood is quite burnt and reduced to ashes, the Fire goes out; because that which was there before, flies away, and no more follows it. For *Flame is alwaies in generation and being bred it perishes immediatly*, as *Theophrastus* speaks in his *Book de Igne*. For while the fire is made by consuming the fewel, when the fewel is gone the fire goes out. For the fire properly does not die or perish, but flies away: yet because it sticks so long to the inflamable Body, as long as there is any thing to be kindled and burn, when that fails, it is thought to die. This first manner of extinction, which is caused by defect of fuel, is by *Theophrastus* in his *Book de Igne* called, *A Corruption allmost Natural, and most properly so called.*

1. *Either through deffect of inflamable matter.*

Touching the kindling and going out of Fire, *Galen* hath an excellent place *in his Book de respirat. Cap.* 3. Where he writes: *All flames are moved with a double motion, the one from the matter, out of which they are kindled, by which they mount aloft and spred abroad every way; the other contrary to this, is to their beginning and their Roots as it were, by which they settle and are contracted. For if you light a brand on the very top, the fire comes suddenly to the lower parts; and if after you have blown out the flame of a candle, and you shall hold another candle over the Smoak of the snuf, you shall see it presently lighted, which could not so fal out, if the fire moved only upwards.* And he adds that this is the cause of the said double motion, *seeing* (saith he) *every flame is most speedily corrupted: for it is alwaies scattered by the ambient Air, therefore it is necessary that its generation should also be very quick; otherwise it would not last the least moment. Now the generation of all flame comes out of the matter, therefore it hath not without cause given it by Nature, not only a motion outwards from its proper principle, but one contrary thereunto, turning towards its own proper principle. And all flame must needs be corrupted, if it want either matter, or one of these motions.* In which place of *Galen*, those two motions of flame, are diligently to be considered. First, The Fire is carried to the Body inflameable, and the matter, or Root, as *Galen* cals it, by reason of affinity, and it goes on al sides: the other is whereby the fire which is drawn out, is naturally carried upwards.

The double motion of a flame according to Galen.

The cause of this motion.

Now the waies whereby the inflameable matter being present, the flame nevertheless decaies, are many, which all of them have this in common, that in the extinction, the actuated fire goes away, and no more actuated fire does succeed it, from the mixt Body inflamed.

2. *Or because of no generation of new actuated fire.*

This proceeds first from suffocation; *viz.* when as the fire breaking out of the inflamed Body with the Smoak, finds no place to receive it. For then the fire ceases to be moved in the fume or Smoak. For seeing, as was said before, two bodies cannot be in the same place, least there should be a penetration of dimensions; and in the inflamation, of mixt Bodies, many exhalations go away with the Fire which fire which raised them; if they find no place to receive them, their evaporation together with the flame is hindred, by the necessary working of universal Nature. After this manner, all things that deny place to the Fire and the exhalation joyned therewith, do extinguish the fire, and stifle the same: which happens when the flame and fume are so shut up, that they have no free egress, nor place to hold them.

which comes to pass again.

1. *Either by suffocation*

Its

Hereunto belongs a soextinction by thick Air.

Its also a kind of suffocation, when the flame is extinguished by thick Air and exhalations; which comes to pass in the quarries of metals, the pumpes of Ships, and when Beer and new Wine works. For seeing the Air is then filled with thick vapors, it cannot contain the flame with its exhalation, whence its motion must needs be stopped and choaked in its Root.

Also the compression of the Wiek.

To suffocation also, compression may be referred, when the wiek being compressed, the flame of Candles is put out unless any one will refer this to the following manner, whereby fire is violently separated from its Fuel and Root as it were.

2. *Or by discussion and dissipation*

Secondly, A flame is extinguished by discussion and dissipation, when the flame is pluckt away and so departs from its fuel and Root, before new fire can follow, and when the fire is taken away, which drew out the fire in the mixt body. After this manner Torches are blown out by Winds, and we blow out Candles and Lamps with our Breath. And seeing by the blast of ones Mouth or by Bellows, flame is raised, and the fire in Coals turns to a flame, we must enquire the cause of these different effects. Where we are to know; if a little flame do only stick in the surface of the Body, it is soon extinguished by blowing, whereby the incendiary, and the fire into which the mixt Body is resolved, are soon taken away. But if the fire, actuated by blowing, is driven into the inner parts of the Body inflameable the fire is more and more encreased. Thus, by blast of the Mouth, and of the Bellows, the fire is droven into the inner part of the Coals, and flame is raised, which when it hath taken deep root, it is not easily separated, but the fire desirous to preserve it self, alwaies goes more inward, and by that motion, more of the hidden fire is actuated. Which is manifest in Coals. Hence it appears, why as *Theophrastus* saies and experience teaches, Lamps do consume more Oyl, if the Wind blow upon them, then they do when the Air is stil, and torches also are sooner burnt out, when the wind blows. For seeing the flame is prepetually generated, and the Wind or other blast discusses the flame gennerated, the fire sticking close to its principle or Root, does more greedily and powerfully draw out what ever is therein inflamable, and turnes it into flame.

Why flame is both raised and extinguished by blowing

When and why the flame in the wiek, is extinguished & blown in again.

Hence also a cause may be rendred, why the flame being extinguished, is again excited by blowing upon the snuf. Where you must observe that this does not alwaies happen, but somtimes only, when the snuf is large and ful of fire, like a coal. For then, as burning coals by the blast of bellows, do send forth a flame, which otherwise, of themselves they would not do: so also the fire being in great quantity in the snuf, by blowing conceives flame. But if the snuf after the flame is blown out, have not much fire in it, and be not red hot, 'twil be in vaine to endeavour to blow it into a flame,

Why the fire of a flame, is more powerful then that of burning coals.

This also is to be observed by the Way: that the fire of a flame, is much more vehement then that of Coals, and that not without Cause. For all the strength of Fire is in motion. And experience it self witnesses the same. And therefore Gold-Smiths do most readily melt their Gold by a Lamp, the flame whereof they direct upon the Gold by blowing. And others also that work in metal, and amongst them, belfounders do rather use the fire of flame rising from wood, then Coals, and if in other melting fornaces they use Coals, they use the continual blast of bellows to make them flame.

Or by hindring the afflux of new fire.

There is yet a third way, when the flame, though the matter of fire be present in an inflameable body, is extinguished, because that which is first bred, flies away; seeing flame is in perpetual motion, and new fire is hindred from coming out of the inflameable body, or the actual fire is hindred from drawing more out of the inflameable body, or as *Theopraſtus* speaks somwhat shuts up and stops the beginning. Which how it comes to pass, we are now to enquire. which how it comes to pass, must be enquired unto. Some men may refer this to the presence of that which is contrary, which when the fire perceives, it flies from it, and ceases its motion. But, Seeing not only water, but also Oyl and spirit of wine, too abundantly poured about the flame, yea, and Ashes, Sand, and what ever covers the inflameable body, that the Flame which cals out the lurking fire, cannot touch the same, puts out the flame; and 'tis not only contrarity that makes to the extinction of the flame. For the fire in the flame flies away, when it can no longer touch the Body inflamed. And though the Body, which interposes it self, be it self also inflame-

Whether fire be extinguished, by presence of its contrary.

able;

able; Yet, If either by means of the great Quantity thereof, or by reason of the admistion of another Body, it cannot set that body on fire, nor change it into a flame to succed, the former flame flies away, and so no other coming in its place, the fire is extinguished. Yet, because of al things water doth most easily extinguish fire; if any one wil have it, that it puts out fire, not only by interposition of its body, but also by its contrariety which it hath to Fire, I shal not contend with him thereabout.

Why some fire burns under the Water.

But how it comes to pass that some fire burns under water, is an obscure question, nor that I know of, sufficiently explained by any Man. For al inflameable things wil not burn under the Water. For Rozin, Bitumen, Frankincense, Yea, and Brim-Stone it self, if being set on fire they be put into water, they are easily extinguished: and other things even when they are not on fire wil not admit of water, as Oyls, Tallows, Fats. And if these be much heated, and then water poured upon them, there arises a great fight betwixt them and the Water, and the fire flies violently away with a great noise; so that experience hath taught, that fires have been caused by pouring Water on such fat things when they boil. If therefore mixtures be made of such things so fatty, which exceedingly resist water, adding such things as do most of all cherish fire, and keep it from flying away, then those mixtures will burn even in the Water. For a part of such a mixture being inflamed, does vehemently drive the Water from it self, and therefore such things burn with a noise, and hinder the water from piercing into the burning body, and the other things do continually supply matter to the flame.

A Torch that cannot be quenched.

A Torch that wil not be extinguished by Rain or Wind, may thus be made. Take *Colophony and Wax of each six pound, Turpentine two pound, Tallow one pound.* Mix all over the fire. And in this mixture dip Wicks to make Candles, or Cords to make links, let them boil a little and then take them out and cool, and wreath four together for one link. Which must be covered with *four pound of Wax and one pound of Turpentine.*

A Candle that will burne in Water.

A Candle that will burn in water may thus be made. Take *Wax half a pound, Brim-stone, unslak't Lime, Turpentine, Salt Ammoniack, of each two ounces, Petroleum one ounce, Camphire half an ounce.* Mix them and make thereof Candles, which if they be lighted and thrown into the water will burn nevertheless.

Flame is also extinguished when a greater is applied to a lesser.

Besides the manners and waies already reckoned up, whereby fire may be extinguished, *Theophrastus*, in his *B. de Igne*, hath yet another, *viz.* When a greater fire is put to a lesser. So we see, a great Candle lighted and put to a lesser, puts the lesser out. But then the lesser flame indeed is extinguished, but the fire in the Snuf is not put out: and the fire and flame do not go away, only the lesser flame goes to the greater, because of affinity, and is thereto joyned; or the lesser flame is drawn to it by the greater.

Of the operations of fire.

And that we may say somwhat also of the effects and operations of fire; Fire is indeed essentially one and the same, but according to the diversity of the matter wherein it is, it workes diversly. *Fire is most hot in a solid and Earthy Body*, saies *Theophrastus*: but in a thin and rare or spungy body, 'tis less hot. And *Scaliger* in his 9. *Exercitation*: *Fire in Iron is most vehement by reason of its density, in wood less vehement, weaker in Wooll and such Paper as we use; in a flame it is so dilute that we can draw our hand through it without hurt; in Aquæ-vitæ, on fire the flame is so thin, that it will not burn a cloath dipt therein.* Yea, And the same *Scaliger* in the same place saies, that the fire burns not of it self, but by accident, *viz.* Because of condensation. Howbeit, It is a question obscure enough, whether fire of it self burns, and whether some fire be hotter then othersome. *Cardan* hath invented some causes of this thing, which may be seen in *Scaliger*. Now that this question may be more rightly explained, *Scaliger* gives us light, in the same place, who saies the common manner and cause why fire is more vehement then fire, is the frequency of its parts, their Coherence, Propinquity, Coagmentation, Cohesion and union; for in a more compacted matter very many parts are contained in a smal place.

Why some fire is more vehement then other some?

The opinion of Scaliger.

Andreas Libavius indeed opposes this opinion of *Scaliger* in his *Comm. Alchym. Part.* 1. *Lib.* 2. *Cap.* 12. And feigns I know not what intension of substances and qualities, and objects divers things of little validity against him, scarce rightly stating the Controversie. For first he saies, when stubble is loose and spred abroad,

Libavius opposes the opinion of Scaliger.

the fire Flams and wanders at large, and we must say its heat is less because of the dispersion of parts. Take them therefore in your hand, twist them and twind them together, yet the fire becomes no stronger: but the answer is easie. The stubble it self, whether spread abroad, or in a bundle, does not change its Nature, but continues spungy. And therefore it stirs up the same degree of fire, save that when it lies scattered it cannot afford so joynt a Flame, seeing much Air comes between, as when it is gathered together. Again, he saies, that fire burning freely in a spungy piece of Wood hath more furtherances to its action, then in an hard and solid, although you imagine both of them to be totally inflamed. The fire of loose Coals is more spirituous, and more blown through then that of hard Coals, although a greater impression seems to be made by the latter, if you touch them: yet it hath less spirit, it receives less nutriment from the Air; and because it is more shut in, it is more weak, though more lasting in regard of the strength of the matter.

Libavius his objections answered.

But *Libavius* seems, not to have been well acquainted with the Nature of fire, and there are many things in these objections not agreeing with truth, also several questions are mingled together. For the question is not, what material does more easily take fire, and in which fire is most easily brought into act, and which burns most freely. For we grant that al these things are true of Spungy bodies. But the question is, in which the fire burns most, in a rare or a dense body. And we say, that fire does burn more vehemently in a compact and dense body, as experience shews. For a man may without dammage draw his finger through the flame, but if he do but touch a red hot Iron, he is burnt in a moment. Which *Libavius* himself confesseth when he grants, that we perceive a greater heat in hard Coals then in spungy, if we touch them. Now that is false, that the fire receives nourishment from the Air, since whatsoever is lighted must be in the inflamed body. But if fire be allaied with much Air, as happens in the burning of stubble and such like things, the fire is not thereby made stronger but weaker. And *Libavius* confounds the encrease of the fiery parts and the stronger action of the fire depending thereupon, with the intension of the heat it self. That one fire is greater then another is out of question; and manifest also it is, that in a greater Quantity the power of acting is greater, in a less quantity lesser. For that metal which is melted by a large flame of Wood or Coals, will not be melted by the flame of a Candle. But here lies the Question, whether the heat and fire which is in a great flame, be of it self more intense then that in a smal one. Which *Scaliger* denies, for the causes aforesaid, and maintaines, that those parts of fire, which they call degrees, are augmented by conjunction of parts, and not by intension of Virtue. Which opinion of *Scaliger*, though *Libavius* call's it a Nicety; Yet, He must needs allow of it, when he writes that the heat of Fire is as great as may be, in the smalest spark, and of it self suffers nothing to be taken from it, nor admits any part of a cold body into its society. And though he addes that the receptive subject of them both is altered; yet will not *Scaliger* deny this neither. For by how much the more Fire there is in any body, so much the hotter is it; and by how much the lesser, so much the less hot. Take for an example (which *Libavius* himself uses) seething Water. There is in boyling hot Water much Fire, whereupon if you pour cold water, it becomes luke-warm, because of the admixture of cold water, which hath no Fire in it. In a smal piece of Iron there may be more Fire, then in a great deal of stubble.

The Authors opinion.

I retain therefore the opinion of *Scaliger*, and hold, that one Fire is not hotter then another; but that Fire burns more strongly then Fire, comes by reason of the union of many parts; and that fire burns weakly, proceeds from the distance of the said parts. Which that we may understand more clearly, we must know, that Fire is most of all allayed by Air, which easily insinuates it self into the society thereof. Whence it follows, that in rare and porous Bodies, which containe much Air in them, Fire is more weak and dilute, and its parts are not too near. Contrariwise, In solid bodies, into which Fire pierceth where there is little Air, the parts of the Fire do stick more one to another, and are compacted.

Fire burns of it self and not by accident, as Scaliger imagines.

Howbeit from the premises it follows, that fire burns of it self, not by accident as *Scaliger* would have it; contrariwise that it does not burn by accident at al. For, seeing Fire of it self is the hottest of all bodies (though we have no such Fire with us, that is pure) and in pure Fire there is a great cleaving together of the parts there-

of,

of, it must also of necessity burn: which also it does in Iron, and other red-hot metals, because the Atomes or indivisible particles of the fire do Cohere together, and are extreamly near one another, and very many are contained in a smal place, and because of their conjunction they act more effectually. Contrariwise in stubble, and other spungy Bodies, because Air is mixed with the flame; and as *Scaliger* in his 9 *Exercitation* speaks, the fire is allayed by the Air, the parts of the fire do not stick together, but are at distance, the Air coming between, therefore they cannot act so strongly. For Fire truly is the first subject of heat, and the hottest thing of all others: but that it does not allwaies Act to extremity, comes by admixture of other Bodies not so hot, especially of the Air.

What place the Air holds. *Its three Regions.*

The next Element to fire is the Air. For it, as it declines from the rarity and heat of the Fir; so it takes up a room a little more remote from Heaven, and is heavy respectively. The Air is divided into three Regions: the uppermost, the middlemost, and the lowermost. The *uppermost* is above the Tops of the highest mountaines. For imagine but a surface upon the tops of the Highest mountaines, that shall make the Earth exactly round, the Air above the same, to the Sphere of fire is the uppermost Region. The other are below this, which are not allwaies of a like bigness. For in Summer the lowest is greatest, which reaches as far as the reflection of the Sun beams goes; and in Winter the middle Region. For in summer time when the Sun beams fal to righter Angles, they are reflected higher; but in Winter, the Beams of the Sun being very oblique, are reflected sidewaies, nor do they rebound aloft. The middle Region, in respect of the two others is least hot, and therefore it is said to be cold, because the Sun beams are not reflected so far: the other two are hotter; the uppermost, because of the Vicinity of the Heaven and the fiery Element; the lowest because of the doubled Sun beams, direct and reflex.

Howbeit the lowest Region is variously disposed, somtimes 'tis hot, otherwhiles cold, somtimes moist, otherwhiles dry, somtimes clear, otherwhiles cloudy; and the Air being in this Region variously disposed, does diversly affect our Bodies. For while we breathe, we continually draw it in, and by it the spirits in our Bodies are repaired and cherished, and our heat which in the Body needs continual fanning, is thereby preserved.

The Water.

After the Air comes the *Water*, an heavy Element, yet somwhat lighter then the Earth. This Element is no where found pure, but is every where mixed with the Earth and ambient Air; of which the taste is an argument, seeing you can hardly finde any Water void of taste.

The Earth.

The lowest place is taken up by the Earth, which is of all Elements the most heavy, and most unfit for motion. It hath much matter, and is therefore thick and dark. The Earth is not found pure on the top thereof, but if it be any where pure, it is in the Centre, whither no contrary does pierce, that may corrupt it.

The Water and the Earth do not make a peculiar sphere.

The Water and Earth do not make a peculiar Sphere as the rest of the Elements, nor does the water compass the Earth on all sides, but the Earth receives the water within its Cavities; and in very many places, by a singular providence of God, the Earth stands bare, for the more commodious generation and nutrition of Animals and other mixt Bodies, and it lies open to receive the Raies of the Stars. For Beautifulness and Commodity overcame the force of necessity, in respect whereof, the water was to have covered the whole Earth. As *Scaliger* saies, in his 9. *Exercitation.*

Now, How great the Earth and Water is can hardly be determined. That the compass of the whole Globe made up of Earth and water is 18000. furlongs, or 5400 German miles, and the Diameter thereof about 1718. German miles, is a thing out of question: but 'tis hard to say whether there be more Earth or Water: Yet most likely it is, that there is more Earth then Water. For neither is the greater part of the surface of the Globe of the Earth covered with Water, as appears by the true description of the said Globe: nor indeed is the quantity of the Water greater then that of the Earth; seeing by the sounding Plummet we discern that there is Earth under the Sea; and the depth of the Sea compared with the diameter of the Earth, is a thing of smal moment. Of which see *Alexander Piccolhomineus* in his *Treatise of the Largness of the Land and Water.*

The water with the Earth makes one Globe.

And, that the Sea is not flat and even, but that it makes one Globe with the Earth, is proved, first by Eclipses of the Moon, in which the shadow of the Earth appears circular; and therefore argues the Body of the Earth to be so likewise; and in the next place by Navigations: For if a man sail out into the main Sea, and take notice of some House or turret on the shore, at first he sees it all, afterwards scarce half, til at last he quite lose the sight of it, because the swelling roundness of the Water interposes it self between the shore and the mans Eye; for sight goes alwaies in a right Line. And although the Earth it self be not an exact Globe, but a Globous Body, high in some places, low in other some: yet this highness and flatness bears scarce any proportion to the whole Body of the Earth; which appears by Eclipses of the Moon, wherein the shadow of the Earth appears Circular, and makes a Circular Line.

THE THIRD BOOK.

Chap. 1. *Of the Elements as they are the Principles of mixt Bodies.*

The definition of the Elements.

Since in the Sublunary part of the World there is a perpetual Interchange of the generation and corruption of things, there must needs be some immediate Principles, of which variously mixed and tempered together, all things are generated. These Principles are vulgarly cal'd Elements, and by *Aristotle* 3. *de Cœlo, C.* 3. *T.* 30. thus defined. *The Elements of Bodies are those things into which the Bodies are resolved wherein they are actually or potentially, but they themselves cannot be divided into other distinct sorts of things.* And by *Avicen* they are defined to the same intent and purpose: *That they are simple Bodies, and the first parts of the Body of man and other things; which cannot be divided into Bodies of different forms, of the mixture of which, the several sorts of things generated are made.* Where you are to observe, that the chief Character of an Element, as it is the principle of a mixt Body, is indivisibility, in respect of any parts of several sorts, into which it can be divided. And therefore *Galen* also, when in 1. *de Elem. Cap.* 1. He had defined an Element to be the smallest part of that whereof it is an Element, himself adds; but that which appears smallest to the sense, is not indeed alwaies the smallest in reality. For many things by their smalness cannot be discerned by the senses.

Seeing these Elements were to be the Principles of a tangible and generable body, it was necessary that they should have also certain Qualities, by which they might be known to us, might work one upon another, and might be fit to effect all kind of mixture: which what and how many they are, let us consider in the first place. For they being known, we shal easily afterwards know, both how many Elements there are, and what their Nature is. These qualities are commonly called the first Qualities, not because they are absolutely first, or first in dignity, or because all other Qualities arise from them, but because they are originally in the first sublunary bodies.

The first Qualities, why so called.

Their Conditions.

Now these are their Conditions: that they constitute the first sensible, that is to say, tangible bodies, and be their differences as they are such: that they effect the first sense, *viz.* the touch: that they be in all bodies subject to Generation and Corruption: that they be contrary, and apt to do and suffer; for they are to be the Authors

of

of Generation and Corruption: that they have none before them, whence they are termed first: that they cannot be made one of another.

How many first Qualities there are?

Moreover, that we may search out how many such Qualities there are, we must take a view of al tangible Qualities. *Aristotle*, in his *de 2. Generat. & Corrupt. c. 2. t. 8.* reckons up these first tangible Contrarieties; Hot, Cold; Dry, Moist; Heavy, Light; Hard, Soft; Clammy, Crisp; Rough, Smooth; Thick, Thin. Howbeit, among these seven Oppositions of tangible Qualities; only the two first deserve the name of first Qualities. For Heavy and light do not act one upon another. And the same may be said of the other four pair of Oppositions. For neither do they act or suffer one upon and from another; nor are they first Qualities, but arise from others, and belong rather to compound than to simple Bodies. And therefore there are only four first Qualities: Heat, Cold, Driness, Moisture. For in them al the abovesaid marks of first Qualities are to be found.

The definition of Heat.

These Qualities are defined by *Aristole* in the *2. de Gen. & Corrup. ch. 2. t. 8. and 9.* thus: *Heat is that which collects things homogeneal or of like nature.* For in that it separates things heterogeneal comes by accident. For to collect and gather together things of like nature, is to separate things of unlike nature Now by things *homogeneal*, or *of like nature*, we must understand, not only such things as are of the same sort, *but which have like temper, and may be changed into one nature*: by things heterogeneal or of unlike nature, not only such things as are of a different species or sort, but also *such as are of a diverse temperament, nor can be reduced into one nature.* For Heat alwaies endeavors to reduce things different into one Nature: which since it cannot do, by reason of the difference of temperaments, it only unites such things as it hath made alike, and rejects the rest as Excrements. These operations of Heat are every where to be seen, and especially in the Concoctions made in animals. For the soul makes greatest use of heat as its fittest Instrument to perform its actions by. For sundry meats being cast into the stomach, the Heat of the stomach reduces such as are fitting into one nature, and turns them into one mass of chyle; the other parts which are unfit, it separates as Dregs and Excrements, to be cast out by the Guts. The same does the Liver; the same do all the members. Also by the help of Heat all chymical operations are performed. For that Art by Heat separates metals; severs the parts of Plants and other things, and does other wonderful works. *Heat* therefore *is of all Qualities the most excellent; the first Instrument of Generation, and most efficacious in its operations.*

Cold defined.

Cold is a Quality that gathers together, both things of like, and things of unlike Nature. For we see how in Ice, by force of cold, several things, as Wood, Straw, Stones, Earth are congealed together; and the like cold does in other things and places; and it combines things together without any separation of what is heterogeneal. Here we must reject the Opinion of *Cardan*, who would have cold to be only a defect and privation of Heat. For Cold is doubtless a positive Quality; seeing it is perceived by the Sense, and hath certain powers whereby it acts and opposes Heat; which cannot be in a bare privation. Of which see *Scaliger in his 18. Exercitation.*

The Definition of Moisture and Driness.

That is moist, which is hardly contained in its own limits or bounds, easily in those of another thing. That is dry, which is easily contained in its own bounds, and does not easily receive the bounds of another thing. For we find by Experience, that the Air does of it self flow every where al about, and easily accommodate it self to the sides of the thing contained; and the like does Water: but the Earth flows not about, but retains and keeps within its own bounds: nor does it easily accommodate it self to all the parts of the body which contains it. By Moisture therefore things are made to cleave one to another; and therefore we see things overdried do break: and from driness things have stability and Consistency.

Now touching these definitions, this is to be observed: that *Aristotle* did not define the first Qualities absolutely considered, as they are in the Elements, considered as simple bodies and not compounded into mixt things; but as they appertain unto them, when they go into a mixt body. *Aristotle* was not indeed ignorant, that the first Qualities had other effects preceding those by which he defined them; and that an Hot thing Heats, a Cold, Cools; a Moist moistens, and a Dry Dries; yet he thought not fit to constitute or make up the definitions of the first Qualities by these effects; both because these definitions would reveal nothing that was hid-

den

den, but the same thing would be defined by the same; and also because the first qualities are given to the Elements by Nature, for no other occasion but that by them as the immediate instruments they might be the principles of mixt bodies. And the first operations of the first qualities are originally more principal than the second operations of the said Qualities: but in the intent of nature contriving the generation of a mixt body, they are not the principal, but the second are more principal than they. Wherefore, omitting those common operations known of themselves, which they perform both in mixt and simple bodies, *Aristotle* would define them by those alone which they exercise in mixt bodies.

Whether the first Qualities are rightly divided into active and passive

These Qualities are divided into *Active* Heat and Cold; and *Passive* Moisture and Drineſs, of which division, although the opinions of Authors are various, as may be seen in *Archangelus Mercenarius, p.* 239. *Zabarella de Qual. Elem. c.* 5. *Franc. Piccol. de Qual. p.* 1. *cap* 8. yet I conceive, this ought to be our judgment. All these qualities, in respect of that univocal action, whereby each one by its first operations begets its like, and destroies its contrary, as wel in simples as in mixt bodies, do both act and suffer: yet in respect of their equivocal action, which they only exercise in mixt bodies, and whereby they produce the second qualities, and the nature of the mixt body it self, different from the nature of the Elements; two are termed active, and two passive. And in this respect, Moisture and Drineſs have no active power, but are only as matter which the Work-masters Heat and Cold exercise their craft upon.

Seeing these Qualities are in the Elements as in their first subjects, we may rightly by them search out also the number of the Elements. And omitting that reason which was produced in the second Book foregoing, we shall thus proceed. If the Elements be alterable, they must needs be more than one: but they are alterable, for they must be the principles of alterable bodies, and bodies that are corruptible. Therefore there cannot be one Element but many, and they endowed with contrary qualities, by which they act and suffer mutually. This reason agrees with that of *Hippocrates, Lib.* 7. *de Nat. Hom. t.* 5. where he saies: if a Man consisted only of one Element, he should never be pained: for there would be nothing to pain him, because he should be one thing; and, as *Galen* saies in his Comment, there would be no second to act upon him. For the self same body cannot suffer from it self.

The number of the Elements.

Now how many Elements there are, *Aristotle* demonstrates *in his* 2. *de Gener. & Corrup. cap.* 3. *t.* 16. and *cap.* 5. *t.* 34. after this manner. The Elements are therefore called the principles of mixt bodies, because being altered and changed one by another, they constitute the said bodies. Now all alteration and mutation depends upon the action and passion of the first Qualities, which are four as was said before. Those simple bodies therefore which are the subject of the first Qualities, shal be the principles of mixt bodies. And that they may rightly cause mistion, 'tis necessary, that each may suffer from each, and that therefore it have not only one, but two first Qualities.

Whether the first Qualities be the forms of the Elements.

From the Premises therefore, thus we conclude. There are so many Elements, as there are possible combinations of the first Qualities: but they are only four; Heat and Drineſs; Cold and Moisture; Heat and moisture, Cold and Drineſs: for the other two are altogether impossible, nor can extream Heat combine with extream Cold, nor extream Drineſs with extream Moisture: seeing contraries cannot be in one and the same subject. So many Elements therefore there are; The Fire hot and dry; the Air, hot and moist; The Water, cold and moist; and the Earth, cold and dry.

Hereunto may also be added another reason, which *Aristotle* uses in his 2. *de Generat. and Corrupt. Cap.* 8. *T.* 40. So many Elements there are, as there are things of which perfectly mixt Bodies do consist. But they consist only of four: and therefore there are four Elements. For we see all perfectly mixt Bodies to have much Earth in them, and to be moved towards the Earth: but mixt Bodies are moved according to the motion of the prevalent Element. And mixt Bodies because they are knit together and Co-here, and receive terms, there is also water in them, for it is the part of Water to unite and fasten: if Water and Earth, then the contrary Elements Fire and Air, by which they are to be allaied, and wherewith to be mingled. For mixture is not made without mutual action and passion. Moreover

all

all Generation is made by Heat. And therefore besides water and Earth, heat also is required to mixture: but one hot Element doth not suffice: For it would be vanquished by two cold ones. And therefore, besides Water and Earth, Fire also and Air do concur to constitute all mixt Bodies.

Whether the first qualities be the forms of the Elements.

The number of the Elements being found out, we must now enquire into their Essence and Nature. And since the first qualities are very intimate to the Elements, the question is; *Whether the first Qualities are the substantial forms of the Elements?* Or whether the Elements have other forms besides the Qualities. Not to be prolix in a plain case, briefly thus we hold; that the first qualities are not the substantial forms of the Elements, but accidents. A token whereof is, that the first qualities are perceived by the sense; whereas no substance can of it self be perceived by the sense; again they are found in other things as mutable accidents; and therefore in the Elements themselves they cannot any waies be substances. Howbeit the hidden Forms of the Elements are by them Circumscribed by Authors. And therefore *Hippocrates* himself, oft calls the four Elements by the Names of Hot, Cold, Moist and Dry, as *Galen* witnesses in his 1. *De Temp. Ch.* 8.

The qualities proceed from the Forms.

By the Qualities therefore the Elements are known to us. For they are in the Elements as their Proper subjects, from whose forms also they depend and have their being. For I hold not with those who deny, that the first Qualities which are in the Elements do proceed from the forms of the said Elements, by way of Emanation, but derive them all from the motion of Heaven, or the Negation thereof. For 'tis an absurd thing, that a Natural Quality should proceed from any thing but its own Form. Nor must we think that the forms of the Elements are Lazy and Heartless, and produce no Qualities, nor work no operations. For if the first proceed not from the forms, which are most intimate with the Elements; I do not see what other Qualities can proceed from them: moreover an absurd thing it is, to hold that cold comes only from the Privation of the motion of Heaven: for since it is a positive Quality, it requires also a positive Cause.

Each Element hath two qualities.

But *in each Element there are two Qualities.* For seeing it is necessary, That every Element, for the more commodious generation of things and their mixtion, should be able to act upon every one, and suffer from every one: therefore each have two qualities. Now the Question in this place is; whether both Qualities do equally agree to each Element? *Or whether one Element have affinity to one Quality more then another, and have one Quality primarily, the other secondarily*: Moreover; *Whether in each Element both the Qualities are in the highest degree,* Or one only in the highest degree, and the other remiss: and it is disputed, how that place in *Aristotle* 2. *de Gener. and Corrup. Cap.* 3. *T.* 23. is to be understood; where *Aristotle* thus saies: *The Earth is dry more then cold, the Water cold more then moist, the Air moist more then hot, the fire hot more then dry.*

Whether each Element hath one quality in the highest degree?

'Twere long to recount the different opinions of Authors touching this Question, and to make any certain determination is hard: yet I shall briefly propound what I conceive most probable. Now we hold, that that one quality is most intimate to the Nature of each Element and more of alliance thereto then the other: also that one is more excellent, the other less excellent, *viz.* That the fire, as *Aristotle* hath it in the place forealleadged, is most Hot and Dry; the Air most moist and hot: the Water most cold and moist; the Earth most Dry and Cold; which also sense does testifie: and that these Qualities do after this manner flow from the form of each Element. And they are in an Error, who while they are sollicitous about attributing to each Element its own Qualities, do not so much regard the forms of the Elements, as their greater or lesser distance from Heaven, and think thence to fetch the qualities. Nor is that of any great moment, which hath moved many to think the contrary: *viz.* That the abatement of the quality is caused by its contrary; whereas the Elements are most simple, and have no contrariety in them. For this is true only of mixt bodies, but not of simple Elements: and that constitution of Qualities doth proceed from the form of each one. For as this is the Nature of the Air, that without the mixture of any heavy Body it is not so light as the fire; so it is a property thereof, not to be so hot as fire.

And

Whether the Qualities wherein the Elements partake, are of several sorts.

And here is also another Question, whether *symbolical Qualities*, for example sake the Heat in the Fire and the Heat in the Air, are of the same sort. Now the Answer is, That these Qualities are not of several sorts, and that we are not to acknowledg eight, but only four first Qualities, which in the first place our Sense it self doth witness, which judgeth all heat to be of one sort: and again when the symbolical Elements are changed, the Quality wherein they partake abides: and the watry coldness it self is as contrary to the heat of the Air, as to the heat of the Fire.

From what has been said may easily be collected, what is the nature of each Element. For the *Fire* is an *Element exceedingly and primarily hot*, and *Dry*. Both which experience does witness, wherby we are all dayly instructed that Fire is dry. For Fire can change both Air and Water. And therfore it must have Qualities contrary to them. For transmutation happens betwixt contraries; and whereas both the Air and Water are moist, the Fire contrariwise is dry.

We must therefore reject the Paradoxical opinion of *Johannes Baptista Montanus*, who teaches that the Fire and all Elements have some moisture in them, and that whatever is continued in Nature and united, whether it be simple or compound, is continued only by humidity, and that not only in this sublunary world, but in the Heaven also. For in mixture only it is, that divers simple bodies are coupled by moisture: not simple bodies, for so they should not be simple. But the form of every simple body, as it gives the being and bounds, so it couples and contains the parts.

The Fire compared to a King.

The Fire therefore, seeing it is Primarily and principally hot, al hot operations are therefore therein more conspicuous: and therfore it is neatly by *Scaliger* compared to a just King, which renders every one his due, dividing the Land amongst families: and to a prudent steward of an house that reserves to himself as much as he needs. For out of Wood, it gives ashes to the Earth, liquor to the water, vapor to the Air; and takes that to it self which is concealed from the Eies of the Vulgar, but not from the mind of the Wise. And although very many in this age seek to banish Fire out of the Universe: yet I conceive we ought not to reject the same, as hath been said before in *B. 2. ch. 3.*

Air is most moist and hot.

The Air is hot.

The Air in the highest degree and primarily moist. Now touching the heat thereof, there is great difference amongst Authors. For the Stoicks as *Seneca, Nat. Quest. Book 2. Ch. 10*, Cardan *Lib. 2. de Elem.* and others do hold against the Peripateticks that the Air is cold. But I must take part with the Peripateticks for the heat of the Air; seeing there are strong reasons to back that opinion. For Air is produced and preserved by that which is hot: but is condensed by cold, and turned into water. Moreover the lightness of the Air is a token of its Heat, seeing Lightness follows after or accompanies Heat. Moreover, if the Air were cold, there would be no simple body hot and moist, and water should agree with Air, and therefore one of the two would be superfluous. More reasons are to be found in Authors to this purpose. But all which is said of Air in this case must be understood of it, as it is a pure Element. For being mingled with vapors, and affected with a strange quality, it hath oft-times a faculty of cooling, and oft-times of drying, which nevertheless agrees not thereto of it self, but by accident.

Water is an Element most cold, and moist. Earth an Element most dry and cold.

Water is an Element in the highest degree and primarily cold, and moist: the Earth in the highest degree and primarily dry, also cold. Concerning these two Elements few Controversies are started. For whereas some dispute, whether the Earth or the water is primarily cold, the question may easily be determined, from what hath been said. For they which would have the Earth colder than the Water build upon a bad foundation: *viz.* that all the Elementary Qualities proceed from Heaven, which was before rejected. *And so much for the Elements.*

Chap.

Chap. 2. *Of the Action, Passion and Mixture of the Elements.*

After we have explained the Nature of Elements, the next thing is, that we declare, how mixt bodies are of them compounded. Now forasmuch as the Elements, unless they be altered, cannot constitute mixt bodies; nor can they be altered unless they act and suffer one from another; nor can they act and suffer, unless they touch one another, as *Aristotle* hath it, *de Generat. & Corrupt. Lib.* 1. *cap.* 6. *t.* 43. we must first speak a little concerning Contact or mutual touching, Action, passion and Reaction.

Contact is chiefly twofold: one improperly so called, which they term virtual; whereby things incorporeal do act upon other things, or a distant body, doth by its Virtue work upon another remote body. The other is a Contact of magnitudes; of which there are again many fashions. For absolutely and generally al things are said to touch, which having distinct magnitude and position have their extream parts close one to another. And then there is a Physical or Natural Contact, of which we are now treating; and this belongs to bodies having divers magnitudes, whose extream parts are together: and which act and suffer one upon and from another. Or in a word: Those bodies touch with a Physical contact, whose bounds are together, and which mutually act and suffer one upon and from another. For besides these things which are common to all bodies that are said to touch one another, *viz.* to have magnitudes distinct, a certain position of parts, their place and extream parts together; this is peculiar to Physical contact, that bodies which do thereby touch one another, do act upon and suffer from one another. Thirdly, Those bodies do touch one another, whose extream parts are together, and one only acts upon another, but suffers nothing therefrom.

Contact is therefore required as a necessary condition in sublunary things. For it hath been before proved in general, that every Agent must be together with the Patient. For since by the Agents action upon the Patient, some mutation ought to be made, of necessity that must be present which changes, or at least its Virtue; and its Virtue cannot be present, unless that be present which carries it. And therefore in every action the Patient is toucht by the Agent, or at least by that which carries its Virtue. For nothing acts upon the extream, but it acts first upon the medium.

Yet we must here diligently observe; that there is a double action, the one primary, which immediately follows the nature of the thing; the other secondary proceeding from the primary. The primary action of the Sun is Illumination: the secondary Heating. The primary action of the Fire is to heat; the secondary to melt, to harden. Now touching the primary 'tis only true, that the Agent acts not upon the extream, before it act upon the Intermedium. For the second Action, besides *that* that it presupposes the first, also it requires an aptitude of the subject to suffer; whence that vulgar assertion in the Philosophck Schools, The actions of Active things, are received in a Patient and that which is disposed also, Whatever is received is received according to the disposition of the Receiver. So by the Sun light is produced, both in the Æthereal and Elementary world; but the Heat not in Heaven, but only in sublunary things. So Fire heats both Wax and Clay; yet it melts the former and hardens the latter: because the former is indisposed to be hard, and the latter is indisposed to melt.

With the Mutual contact of the Elements is conjoyned their Action and passion. Now by action we do not here understand every action, but that only which is betwixt the first qualities, Now among what things there might be Action, the Ancients were not agreed, as may be seen in *Aristotle, de Generat. & Corrupt. Lib.* 1. *Cap.* 7. *T.* 46, 47. For some held, that all action and passion was betwixt things unlike; others, that a thing did not suffer from a thing unlike, but only from its like. We with *Aristotle, in the place aforesaid, Text* 50. do hold the middle opinion, and do say: that every agent endeavours to make the patient like it self, and that therefore a thing like as it is like, and according to the same quality whereby it is like, does not act upon its like: for examples sake, that which is cold, as it is cold, does

not act upon a cold thing: nor does that which is diverse, act upon that which is altogether diverse; for Heat does not act upon heat: but contrary acts upon its contrary. And therefore those things which act one upon another, and suffer one from another, are partly like and partly unlike; like in Kind, but unlike in sort; for contraries are under the same kind, but differ in the sort.

Howbeit, What hath been said, that like does not act upon its like, must be a little more diligently weighed: because from the right understanding of this Axiom, we come to the knowledg of many things in Natural Philosophy and Physick. In the first place it must be observed, that in this place, we speak of that similitude which is betwixt the first qualities; and in the next place that this similitude is three-fold. For some things are alike, only according to the sort of quality; although in the degree, or the intention of the quality and vehemency of the action, which they cal activity, they are unlike. So every hot thing is said to be like another hot thing, and fire is said to be like lukewarm Water, and other things any waies hot. Other things are alike, both in the sort and the degree of the quality, although they differ in the vehemency of their action: thus the fire in a red hot Iron, is like that in burning wood. Other things are a like, both according to the sort of the quality, and according to the degree thereof, and according to the power of acting. So two fires, which are in matters of the same bigness, and of the same rarity or density are alike. For this must not be forgotten; that equal activity does not alwaies proceed from the same degree of quality; nor hath every heat which is alike in degree and intension, an equal faculty of heating, but oftentimes where there is no excess of degree, there is yet an excess of operation, either by reason of the plenty of matter, or the density thereof. For the fire which is made of a great Faggot, is not hotter or more intense then that which is made of a stick or two; but only hath a greater activity; and a dram of Pepper is not according to the degree of heat more intense, then one Pepper Corn: but only hath a greater power to act. For in a greater magnitude there is more virtue: and in much matter, much form. So the fire in a red hot Iron, is not hotter then that in stubble: but it hath a greater strength to act. For force united is more strong then that which is dispersed: and an agent the nearer it is to the Patient, the more it acts thereupon. Now the parts of a compact body are less distant from any particular point in the patient, then the parts of the same Body rarified, and extended to a greater bulk. Moreover, in a dense Body, there is more matter, and therefore more form; and by compactness of parts, there is more substance in a less space, and therefore greater force. For parts condensed are like many individuals joyned together, which act more powerfully then one. And therefore wherever there are more degrees of the same quality, whether they be collected by intension, or the magnitude of the subject, or the condensation thereof, there is the greater Action.

What kind of action there is betwixt like things.

These things thus premised, we shall deliver our opinion concerning the action of things like, in these propositions. I. *Things like may act one upon another after the first manner, so that the more intense will intend the more remiss; and that which is remiss will abate that which is intense.* According to the common Axiome of Physitians, which is a principle of the Art of compounding of Medicaments. For seeing action is betwixt contraries, not only the extreams do mutually act one upon another, but also the Mediums and the extreams. For even by the Medium, as a contrary, muration is made. For as *Aristotle* hath it in his 5. *Phys. Cap.* 1. T. 6. *A Medium is in some sort an extream.* And that which is remiss, is in place of the other contrary. And *Aristotle* himself explains what he understands by contraries, in 1. *de Gener. & Corrup. Ch.* 7. T. 51. *Now because the Agent and the patient are the same and like in kind, but unlike in sort; and such things are contraries: it is manifest, that actives and passives are one contrary to another, and also Mediums.* Also experience proves the same thing, which teaches us, that a hotter thing added to a less hot, makes it more hot, and contrariwise; and that lukewarm Water put into that which is boyling hot, does allay the heat thereof; and continually from the mixture of that which is intense with that which is remiss there results a compound, more intense then the remiss parts and more remiss then the intense.

II. *Among things like, according to the second way, there is no action.* For seeing according to the sort and degree, and the first act, wherein the Nature of qualities consists, and to which mutation tends, these qualities are like, and are not of different sorts; and therefore are not contraries: therefore there can be no action betwixt

twixt them. For every action is betwixt contraries, and every agent by acting endeavours to make the Patient like it self, and to give it the same Nature and Act. Moreover, since action supposeth essence, no thing which is in aptitude to be this or that, can be made actually so, but by that which is actually such. And therefore a thing hot to four degrees, though it may be intended to more degrees; yet it cannot be by any thing intended, save by that which hath above four degrees of heat in it. Also experience justifies our assertion. For suppose for examples sake, that there are two Bodies in the highest degree hot, the one greater and more compact, the other less and more spungy; the former indeed acts more vehemently, Yet can it not work upon the latter, because it hath already attained the highest degree of heat.

III. *Also between things alike after the third manner, there is no action.* For seeing it is rightly said by *Aristotle*, in is 1. *de Gener. & Corrup. Cap.* 7. T. 31. That *the Agent doth make the Patient like it self*: Betwixt things perfectly like, there can be no action. And from the premises it appears, betwixt what things there can be action and passion; which *Aristotle* hath briefly comprehended, in the foresaid place, where he saies: *It is manifest both that contraries, and those things also which are Mediums, do mutually act and suffer, one upon and from another.*

Whether there be Reaction among the Elements.

But here arises another Controversie from that which hath been said, *viz.* That al things of the same kind, do mutually act and suffer one upon and from another; for it is hereupon disputed; *Whether amongst the Elements there be a reciprocal Action and passion*, Which they commonly term *Reaction*: or whether an agent, working by the first sensible qualities of it self, being close to the Patient and contrary thereunto, do suffer any thing likewise from the Patient. Now action is here by way of eminency ascribed to the stronger, and passion to the weaker; and that action by which the Patient acts back again upon the stronger and more potent, is termed Reaction; and the passion whereby the agent being stronger receives the action of the weaker, may be termed Re-passion.

And besides other things, which make a difficulty in this Case, which may be read in *Tolet, L.* 1. *de Gen. & Corrupt. Ch.* 7. *Q.* 15. Zabarella *de Reactione C.* 2. *Franc. Piccolhomineus L. de Effect. & perpes. operant. per Nat. C.* 20. Victor Trincavellus *in Quest. de Reactione.* That passage of *Aristotle*, in his *B. de Animal. Mot. C.* 3. *Whatever things are of equal strength, they do not mutually act one upon another, but are overcome by exsuperancy*, hath brought many into an Error: some so as quite to deny all Reaction; and others who saw it demonstrated by reason and experience, that there was Reaction, so as to make them feigne false manners of Reaction. For some hold, that there is indeed Reaction, but that either it is not according to the same part, or not according to the same Contrariety. For if there be a certaine hot thing, which hath not an equal degree of heat in all its parts, they say it may act according to its strong parts, and resuffer according to its weak ones: but if all parts have equal Heat, then it cannot suffer any thing from the cold patient, according to the same contrariety, but according to some other: as if the fire act upon Water, it suffers nothing therefrom as it is cold, yet it may suffer therefrom as it is moist. Others do thus think: that Reaction is primarily indeed, and of it self, according to a diverse contrariety, but secondarily and by accident, according to the same Contrariety. Forasmuch as one quality may be corrupted primarily by its contrary quality, and accidentally by the Corruption of that, wherewith it is Naturally in the subject: as for examples sake, the Heat of Fire while it acts upon Water as cold, of it self or primarily it resuffers not from the coldness of the Water; yet because the conjoyned driness suffers from the moisture of the Water, it is also therewith debilitated and remitted.

You may read more opinions in the Authors forementioned, all which rejecting, thus we determine: that there is a Reaction; and that it is according to the same contrariety, and the same part, and of it self and primarily, And the first is taught, in the first Place, by experience. For if a Man take a piece of Ice in his Hand, both his Hand is cooled, and the Ice is melted; and a red hot Iron cast into cold Water, it heats the Water, and is cooled by the Water, And Reason proves the same. For reaction being taken away, there will be no Mixture: seeing mixture cannot be made, unless the qualities of the Elements being by mutual action and passion broken and remitted and altered, be reduced to a certain temper and Con-

cord. *Ariſtotle* ſaies the ſame, in 3. *Phyſ. Cap.* 2. *Text* 8. 16. 1 *de Gen. & Corrup. Cap.* 7. *T.* 53. *C.* 10. *T.* 87. 89. *Lib.* 4. *de Generib. Animal. Ch.* 3.

The ſame Experience teaches the other, which witneſſes that boyling Water and Cold, which are only oppoſite in heat and cold, if they be mixed together, become tempered, and that the boyling heat allaies the coldneſs of the cold Water, and the cold abateth the Heat of the boyling hot Water. For unleſs Reaction were according to the ſame contrariety, there could no mixture be made. For if the Fire as hot ſhould only act, and ſhould not ſuffer; the heat and moiſture of the Water would remain in the higheſt degree, and conſequently no mixture would be made. Moreover, every contrary, Naturally and of it ſelf, acts upon its contrary, as long as it is in preſence. Hither tends that, *Out of the* 3. *de Gener. Anim. That which beates is cooled by that which is heated.*

The ſame Experience makes for the Third, and Reaſon teaches, that if there muſt be perfect mixture, all parts of the Elements muſt be altered, and reduced to a Mediocrity.

Experience alſo confirms the fourth, whereby we are taught, that hot and cold Water, which agree in moiſture, and are oppoſite only in heat and cold, can nevertheleſs mutually act and ſuffer. And truly, heat is not peculiarly joyned with moiſture or drineſs, but may conſiſt with either: whence it is alſo that the Elements which have affinity one to another in one of their qualities, do mutually act and ſuffer.

And that we may free our ſelves from that difficulty which hath ſeduced others, we are to know: that there is a twofold action, one imperfect and begun, which they cal an action without the Agents Victory, whereby the Agent does not change the whole Paſſive ſubject, but only weakens the ſame, and impreſſes ſome degree of a quality thereinto: the other perfect and compleat, which they cal an action with Victory of the Agent, whereby the Agent makes the Patient perfectly like it ſelf. Hence, we anſwer, 'tis one thing to act, another thing to overcome; one thing to ſuffer, another thing to be overcome. And therefore, if Action be taken in the firſt manner, for action begun, in every Alteration, there is Reaction, and the contrary Patient reacts upon the Agent; provided it be in fitting diſtance and quantity. For even that which hath leſs force, before it is quite overcome and aboliſhed, makes impreſſion of ſome quality upon the ſtronger, and extinguiſhes ſome degrees of the contrary quality. But if action be taken for a perfect abolition of the other quality, there is no Reaction. For nothing can perfectly deſtroy a thing, and be perfectly deſtoied thereby. Wherefore that ſaying of *Ariſtotle*, before alleadged in his *B. de Motu Animal. c.* 3. muſt be underſtood of this action, and not of the former.

The definition of Mixture.

And ſo much ſhall ſuffice to have ſpoken of the mutual action and paſſion of Elements: we now come to *Mixture* which reſults therefrom, which *Ariſtotle* in his 1 *De Gen. et corrup cap.* 10. Thus defines: *Mixture is the union of things apt to be mingled, being firſt altered.* Now things apt to be mingled, are ſuch as can ſubſiſt ſeparate, by themſelves, and they are only ſubſtances. Hence accidents are neither ſaid to be mingled one with another, nor with their ſubſtances; and miſtion is properly of bodies, not of qualities: again, ſuch things as are contrary, and can mutually act and ſuffer; finally ſuch as can give a bulk to the mixt Body.

whether or no and how the Elements remain in a mixt body?

But here ariſes no light Queſtion, *How Elements remain in mixt Bodies.* For ſeeing the things mingled ought to be altered, not corrupted; it ſeems the Elements remain in the mixt body, but periſh not. Contrarily, ſeeing mixture is not only an heaping or jumbling together of the things mixed, but an Union, ſo that of many Natures one is made; it ſhould ſeem that the Elements do periſh, and that of them a certain new Nature is made: whereabouts, the opinions of Authors are various. We, rejecting the reſt, will follow *Avicenna*, whoſe opinion is approved of very many moſt learned Phyſitians, and ſeems ſo evident and firm to *Fernelius*, that in the *Second Book of his Phyſiology, cha.* 6. he calls the contrary opinion vain and childiſh, Yea and monſtrous, and ſuch he accounts it, as that it ſtains al the Glory of that Philoſopher that holds it. Now the opinion of *Avicenna* is, that the Elements do not only remain in the *Mixt Bodies*, but alſo *retain their forms perfect and entire.* For in the firſt place, ſeeing *Ariſtotle* himſelf, *in the end of his Book*

de

de Ortu & Interitu, defines mixture to be, *The union of the things mingled, being Altered*; The very Nature of mixture declares as much; Seeing things which are not preserved cannot be mingled. Nor does the word union oppose this opinion. For *Union is the coupling of things which truly are*, but not of things which are perished. And though of many things one is made; Yet neither is it necessary that those simples should perish, nor is it a bare heaping together, but by a superior form the simples are reduced into one Body. Moreover, since action supposes an act, and in mixt Bodies the Actions of the Elements appear, it must needs be that they are actually in them. Not to speak of others, *Aristotle* himself, *in the beginning of his* 1. *de Cœlo*, writes that a mixt Body is moved according to the motion of the most prevalent Element. Finally, the resolution of mixt Bodies into the Elements shews the same. For mixt bodies are resolved into the Elements, and *Aristotle* himself holds *in* 1. *de Gen. & Corrup. Text* 84. That the things mixed may be again separated from the mixt Body. Which if it may be, they must of necessity actually exist in the mixt Bodies.

Now their opinion is altogether foolish who hold, that the Elements do not return out of the mixt Body, the same in number, but the same in sort; nor is it founded upon any reason, but is only invented to palliate an absurd opinion; rather it is opposite both to reason and Experience. For whereas they hold, that the Elements return out of the mixt Body, by reason of the action of a like Element, whereby they recover that which they had lost in the Mixture; how I pray you in distillations and burnings, can Water and Earth be drawn out of the compound, seeing the fire by acting upon the mixt Body, introduces nothing Watry, nor any thing Earthy: Yea the action of the Fire is contrary to the Water and the Earth, but does not augment, nor perfect the same?

And that which *Averroes* and *Zabarella* do produce concerning the refraction of forms, is a meer figment, and that opinion is sufficiently refuted by the *Latins*, disputing against the opinion of *Averroes*, who hold the forms of the Elements are capable of more and less; nor have they ever brought so much as a probable reason for their opinion, but only simply affirm, that forms have certain degrees, some of which being taken away, the rest may remain.

Howbeit, not only the Concourse and action of the Elements is requisite, to produce a mixt body, but the direction of a superior form must of necessity by joyned. Which thing also *Scaliger* acknowledged, where in his *Exercitation*, 307. *Sect.* 20. he thus writes, *Unless the four Elements should have a Governour or Pilot, they would vainly and to no purpose toss and be tossed. For what is it that mingles so much Earth with the rest? But there must be in every thing, one thing primarily moved. Now they cannot move themselves to any work, but in Compounds, by a more excellent form, and in things imperfectly mixt, by an external principle, they are moved to a mutual connexion.*

Thus therefore we briefly express the whole Nature of mixture. In mixture the simples must first of all be divided into very smal parts; therefore things Liquid, brittle, fine, are easily mingled. The Elements being thus divided into smal portions according to the Nature of the mixt Body; they do by their contrary qualities mutually act one upon another, and suffer one from another; do heat, cool, moisten, dry one another mutually, and one acts upon another, as on a separated contrary: for they are not as yet united. But becaufe the force of heat and cold is greatest, therefore these things do first temper themselves, and the cold renders the heat temperate and moderate, as far as the Nature of the mixt Body to be produced requires. This tempered heat does afterwards extenuate the moist and dry as the matter, that the parts of the simples may be perfectly mixed, according as the Nature of the mixt Body requires. For heat alone of it self is the Author of mixture; but cold accidentally concurs to mixtion, inasmuch as it moderates the heat.

Chap. 3. *Of the Generation and Corruption of Bodies Natural.*

BUt, inaſmuch as a mixt Body and the Generation of a mixt body are either one and the ſame thing, or at leaſt the one cannot be without the other; we muſt now treat of the Generation of a mixt Body. But, foraſmuch as there are ſundry ſorts of generable and corruptible things, and ſome are ſimple, others mixt, we ſhal firſt ſpeak of generation in general, *viz.* As it concerns every ſubſtance liable to generation and corruption; afterwards, of the ſorts of generation, *viz.* The Tranſmutation of the Elements, the generation of mixt Bodies, and their corruption, which is putrefaction.

The Definition of Generation.

Now Generation as it is taken in General, *Ariſtotle* defines in his 1. *de Gen. & Cor. cap.* 4. *t.* 23. thus: *Generation is the mutation of the whol, no ſenſible thing remaining, as the ſame ſubject.* The Senſe of which definition is this; that Generation is a ſubſtantial mutation, wherein the ſpecifical form of a natural body being aboliſhed, a new one is produced, ſo that there remains not the ſame ſenſible ſubject of the form acquired, which was the ſubject of the form loſt, and the whol compound is ſaid to be corrupted, and a new one generated. For the whol, in the definition of Generation, dothnot ſignifie all the parts of a natural body; for the *prima materia*, or firſt matter is not corrupted: but the Integrity, Abſoluteneſs, and perfection of a natural body, conſiſting in its ſpecifick form; which is therefore by *Ariſtotle* ſomtimes called *Totum*, becauſe it compleats and perfects the whol Eſſence of a thing. For as the ſort of a number is taken away, when one unity is ſubſtracted, and the number of ſeven ceaſes to be ſeven, when one is taken from it, although the other ſix unities remain: ſo, by reaſon of the ultimate and ſpecifick form of a natural body, the whol is ſaid to be changed and to periſh; ſo we ſay, an Horſe is periſhed, though the form only be periſhed, the Body ſtil remaining.

Wherein the Nature of Generation and Corruption conſiſts.

Herein therefore conſiſts the whol Nature of Generation and Corruption, that the laſt and ſpecifick form be aboliſhed, and another ariſe, or be introduced, by which the compound generated may differ ſpecifically or as another ſort, from the former which was ſaid to periſh, when the form periſheth. Hence alſo it appears how that common ſpeech, That Generation and Corruption is not of the form, but the matter, is to be underſtood. For the meaning thereof is not, as if all the parts of a natural body were corrupted, or bred anew; for the matter remains the ſame in all generation and corruption: but that, by the mutation of the ultimate and ſpecifick form the compound it ſelf is changed, and receives a new denomination.

Now that this is the Senſe of theſe words, and what is to be underſtood by the mutation of the whole, theſe following words of the ſame definition declare: *No ſenſible thing remaining as the ſame ſubject.* By which words *Ariſtotle* intimates; that in no ſubſtantial Generation the ſame ſenſible ſubject can remain for both forms, *viz.* that which is loſt and that which is gained. For though the *materia prima* be preſerved: yet is it not ſenſible: which is true not only in the generation of Elements, and of mixt bodies, but even of the generation of Animals. For when a living Creature periſhes, the form which is loſt, is the Soul: but that which is the form of a dead Carcaſs, is an inanimate mixt body, or a congeries or heap of many forms, which conſtitute many and divers homogeneal mixt bodies; and ſo theſe two forms have not one common ſenſible ſubject. For that which was inſtead of a ſubject to the Soul, was the form of mixture: but the ſoul departing, thoſe forms of many homogeneal mixtures do no longer ſupply the place of a ſubject, but of ſpecifick forms, whoſe ſubject is the firſt matter. And although in the generation of a Carcaſs there comes no new form; yet it is all one, as if there came a new form. For the form of mixture in the living Creature, in reſpect of the whol live Creature, did hardly ſupply the place of a form, but rather of a Subject and Matter; ſince in every mixt thing, the Eſſential parts have the ſame reſpect one to another, that every precedent inferior, is to the following ſuperior, as Matter to Form, and aptitude to Act. But when the Soul is taken away, the form of mixture,

mixture supplies the place of the specifick form, and really performs the office of a form, and gives denomination and specifick being to the mixt body; which it did not do before, when the Soul was present.

whether in Generation, there is a Resolution into the first matter.

Out of the Premises an Answer may easily be made to that Question: *whether besides the first matter, any form which was before in the thing corrupted, do remain in the thing Generated; or whether in every Generation there is a Resolution into the* Materia prima *or first matter?* For seeing things perfectly mixed, are either parts of living bodies, or other sorts of bodies natural, as precious Stones and metals; and the generation of these things is performed, not only by the Concourse, and action of the Elements, but by the direction of the upper form: again, it doth not alwaies draw and mingle simple Elements, for the formation of a body necessary to it self, but also the first mixt bodies; therefore it is not necessary, that there should be alwaies a resolution into the first Matter.

The Form of Generation. *The Subject.* *The Efficient.*

Also from the Premises all the Causes of generation may be collected. The form is expressed in the definition, by substantial Mutation. The common subject of generation, is the first matter it self; and the immediate subject, are the four Elements of sublunary things. The general and remote Efficient, is the Virtue of the Heavens: the immediate and adequate, is the Generator or Agent, *viz.* the forms of sublunary things. For they by the first qualities and viral heat, as their immediate Instruments, do make mixt bodies for themselves, necessary for their own preservation, and the performance of their actions.

The End.

But the first matter is not the adequate cause of generation: seeing it is a being, meerly potential, and can beget or effect nothing, but only suffer. And therefore the matter is a cause that the Generation may be made; but the Agent or Generator, is the cause that it is actually made. The End of Generation, is the Conservation of the several sorts of Natural things. For since in the sublunary part of the world there is no perpetuity and eternity of individuals or particular things; Nature conserves the Eternity of every sort, by the perpetuity of Generation.

The definition of generation, agrees also to coruption, as manifestly appears out of the last words of *Text* 22. *c.* 4 *Lib.* 7. *de Gen. et Cor.* and appears from the thing it self. For the generation of one thing, is the corruption of another; as is wel said by *Aristotle* 1. *de Gener. & Cor. c.* 3. *T.* 17. For, since that which corrupted is not turned meerly into nothing, but the matter remains; and it cannot subsist of it self, without any form; it must be, that one compound being abolished, and one form destroied, another form should come, to constitute a new compound. Moreover, since two specifick forms cannot be in the same subject (for nothing can be at the same time under several sorts) it must needs be, that when one form comes, the other which was before in the subject, must give way. Hence also came that saying; That Nature primarily intends generation, secondarily corruption. For one thing cannot be generated, unless another be corrupted. For since the intention of the Generator, is to make the Patient like it self; and this it cannot do, unless it first destroy the form therof: secondarily therefore it desires the destruction of another. And this is the Cause of the perpetuity of Generations and Corruptions; *viz.* Because the matter when it is robbed of one form, receives another; and when it puts on one, it puts off another. Yet it must be here observed, that the Generation of one, is not the corruption of a body of the same sort, but of another of a different sort.

Nature primarily intends generation, secondarily corruption.

Having thus explained the universal Nature of Generation, let us now speak of the sorts of Generation. The Proportion of the Elements which act one upon another is various: For somtimes one contrary only prevails in strength over another, so as to be able quite to abolish the same, and to turn it into its own Nature; and then there happens the generation of one simple Element. Somtimes the Elements are after a sort equal, or at least their inequality is not so great, that one of them can quite destroy the other, and turn it into its own Nature; and then, by mutual action and passion they weaken one another, and making friends as it were, they grow together, into the Nature of one mixed Body. Now we shall speak in the first place, of the generation of Elements. And although, not only *Empedocles*, and other Ancient Philosophers, but also some late writers, deny that the Elements are turned one into another: yet we shall retain the common Doctrine, which is proved by reason and experience. For we see daily, that by fire other

Whether the Elements can be changed one into another.

Elements

Elements are turned into Fire; and water, which of its own Nature is moved downwards, when it is set over the fire, turns to Air and mounts of its own accord upwards, which motion belongs properly to Fire and Air. Now the Reason is this: those things are apt to be changed one into another, which are contraries, and have one common subject. And such are the Elements: for they have the first matter for their common subject, and contrary qualities. And therefore they may be changed one into another. Howbeit, the Elements are changed, not in whole, but in part.

And indeed all Elements are apt to be mutually changed, and there is none of them, which may not be changed into another: for as *Aristotle* saies in 2. *de Gen. et Cor. c.* 4. T. 24. *Generation is out of Contraries into Contraries, and all the Elements have a Contrariety one to another, because the differences are contrary.* Howbeit, these Elements which agree in one quality, as fire and Air in heat, water and Air in moisture, are more easily and speedily changed one into another: but those Elements which are quite contrary and disagree in both qualities, are more hardly changed one into another. For when two things joyned together are to be changed by their contraries, they resist more strongly, then when one quality only is contrary, and the other like; because by reason of that similitude, the approach of the contrary is more easie. And therefore of two contrary Elements, a Medium is sooner generated, then one of another: and we see that of Fire and Water, Air is bred. For the Medium agrees with both, in qualities.

Mixture and the generation of a mixt body, differ not really, but only in respect.

And so much of the Generation of Elements. Let us now come to the simple generation of mixt bodies. Now the *Generation of a mixt Body and Mixture*, of which we spake in the foregoing Chapter, are really one and the same thing: although they differ in respect. For both mixture, and the Generation of a mixt Body, doth signifie a certain progress to the form of a mixt Body, which consists first in mutual alteration, caused by the action and passion of the first qualities; also in the action of the two active qualities upon the two passive, or in the mixture of moist with dry; Finally and chiefly, in the production of the form it self: and therefore both the generation of a mixt body consists in Mixture, and Mixture is contained in the Generation of a mixt Body. For the term union, doth not only signifie a collection of the Elements, and a placing them together; but a production of one Nature, out of several things mingled.

Yet they *differ in respect.* For since both in mixture, and in the Generation of a mixt Body, the Elements are as it were the term *a Quo*, and the mixt Body, the term *ad Quem*; the term mixture, doth chiefly respect the Elements, for the mixture is of the Elements, and not of the mixt Body: but the term Generation respects the mixt Body it self. For *that* is then said to be generated, and not the Elements. Nor yet can the one be without the other; nor doth mixture in time or Nature precede Generation: both consist in the production of one Nature.

The definition of the generation of a mixt body.

Now *Aristotle* defines the Generation of a mixt Body, *in the* 4. *of his Meteors Ch.* 7. after this manner: *Generation is a simple mutation, by the active faculties, when they have their respect, from the matter subject to every nature.* Now, this is the sense of this definition: the Generation of a mixt Body, is a substantial mutation, made by the two active qualities, acting upon the two passive, as their subject matter, and ruling over them in such a proportion, as is necessary to draw forth the form proper to every mixt Body. For the active qualities are not alwaies in an equal proportion to the passive, but variously proportioned, according to the divers Natures of mixt Bodies, which require sundry temperaments. Nor is the dominion of the active qualities over the passive, so to be understood, as though in every mixt Body, the active qualities did in some degrees exceed the passive; since experience doth testifie the Contrary, which teaches, that some mixt things, are to be termed hot, some cold, some moist, some dry, according to the Nature of the over-ruling quality: but this dominion is only to be understood in respect of the form of the mixt Body, to be Generated. For then Namely, the active Qualities are said to rule over the passive, when the proportion of the former to the latter is such, that out of them they might produce some certain form of a mixt Body. For even that which is hot to four degrees, acts upon that which is moist to six, and thereof makes a certain mixt Body.

That

That Queſtion alſo muſt not be here omitted; *Whether in this Caſe the power of the two active Qualities be equal, and their office and Dominion equal.* Touching which we are to know, that both the Generation of the mixt body it ſelf, and the alteration previous to the form, do proceed of themſelves and primarily from heat, and that cold doth no other wiſe concur, then as it tempers and moderates the heat, and makes it fit to produce this or that mixt Body. For the Generation of a mixt Body does chiefly conſiſt in a perfect mixture of moiſt and dry, ſuitable to the Nature of the mixt Body: but this cannot be done, ſave by attenuation, which makes that all the particles of the moiſt matter may be exactly united with the particles of the dry; now extenuation of it ſelf is cauſed by heat, ſomtimes greater and ſomtimes leſs. But cold of it ſelf is not an inſtrument of generation, but rather of corruption. Howbeit, in a mixt body already generated, and conſtituted in its eſſence, even cold alſo acts of it ſelf, and confers thereon its perfection as it were, and aptitude to its operations. For mixt bodies are congealed and condenſed by cold.

Laſtly, after the Generation of a mixt Body, it remains that we now treat of the Natural deſtruction thereof, which is *Putrefaction:* concerning which, ſo great are the Controverſies amongſt learned Men, that ſome late Phyloſophers and Phyſitians have filled whole Books with diſputes about putrefaction. We, though much might be ſaid thereof, ſhall briefly diſcourſe thereupon, ſo much as the Nature of our work will bear. And ſeeing Putrefaction is oppoſed to the Generation of mixt bodies, we may eaſily proceed from the knowledg of Generation to the knowledg of putrefaction. It hath been already ſaid, that the whole Nature of mixture, or of the Generation of a mixt Body, doth conſiſt in a due conjunction of moiſt parts with dry, which is cauſed by heat, in a certain degree: and ſince the Cauſe of the Generation and conſervation of a mixt Body is the ſame; a mixt body ſhall ſo long remain in its Natural State, as there is a due and juſt mixture of moiſt and dry, under a fitting dominion of heat: and the Deſtruction of a mixt Body muſt proceed from the ſeparation of the moiſt and dry parts: which muſt ariſe from the abolition or abatement of Natural Heat. For the Natural heat diminiſhed or aboliſhed, can no longer retain the dry parts joyned to the moiſt. Now the Cauſe which weakens the Natural heat, is the heat of the Ambient Body, which if it be ſtronger, calls forth the Natural. For the Natural heat being encreaſed by the ambient heat, loſes the proportion it ought to hold to the paſſive Qualities, and therefore vapors away, and leaves the mixt Body; whereof the moiſt and dry parts being deſtitute and having loſt their governor as it were, they become ſeparated, and the moiſt parts are carried with the Heat as its conveiance, into the outſide, and ſo vapours away; and ſo comes putrefaction, which is only the deſtruction of a mixt Body, conſidered as ſuch. I ſay the Natural deſtruction, that is, which happens according to the Laws of Nature Univerſal, which wil have all mixt things ſubject to corruption, and to be at laſt reſolved into the Elements whereof they were made: as violent deſtruction of a mixt Body is when the whole is changed into one Element, as by burning, or alſo by overmuch cooling, as ſome will have it.

Putrefaction is oppoſed to the generation of mixt bodies.

All this whole Nature of Putrefaction *Ariſtotle* in the 4. *Meteorol. Cap.* 1. hath comprehended in this definition: *Putrefaction is the corruption of the proper and Natural heat, which is in every moiſt Body, by the Heat which is without the ſame, Namely, in the ambient Body.* Which Definition contains all the Terms of a perfect Demonſtration, and Demonſtrates a proper Affection of its proper ſubject, by its proper Cauſe. The proper ſubject is *a moiſt body.* For nothing can putrefie, unleſs it be moiſt. And therefore *all mixt Bodies putrefie, inaſmuch as they are moiſt.* The next poſitive cauſe is the *Heat of the Ambient Body*; which is not only Air and Water, but every thing containing, which overmuch augments the internal heat, and diſturbs the proportion which it bears to the reſt of the Qualities. Its adjunct is the Corruption of the internal Heat, and of the ſubſtantial form it ſelf.

The definition of Putrefaction.

Its ſubject

The next Cauſe.

Its adjunct.

From theſe things thus explained an anſwer may be made to many Queſtions. For hence that Queſtion may eaſily be anſwered, *Why all things which putrifie become at laſt cold?* Although in the beginning they were hot. The cauſe of the former is the corruption of the inbred heat; of the latter, both the external heat alſo, which encreaſes the internal, is the Cauſe; and becauſe the internal heat, the proportion being

Why all things that putrifie become at laſt cold?

ing disturb'd which it bore to the rest of the Qualities of the mixt Body, going out, doth more shew it self to the sense. For in the mixture it was so tempered, and joyned in such a league of friendship as it were with the rest of the Qualities of the mixt Body, that it could hardly be perceived by the sense; which League being broken in the Putrefaction, it becomes more sensible; and acts more freely.

Why things putrifying, become at first moist and then dry?

And upon this foundation depends that same distinction of Physitians, whereby they say, that some things are actually Hot or Cold, others potentially: and they say that Pepper, Ginger and Wine, are only potentially Hot, because they are not hot to feel to, but only when they are within the Body, and dissolved by the heat of the Stomach. For the Cause hereof is, that Pepper, Ginger and Wine, although they contain much heat in them; yet the same is so tempered with other Qualities, that is doth not put forth its force, while it sticks in the mixt Body abiding in its Natural condition. But when a man hath taken them into his Stomach, that same harmony of qualities is dissolved and disturbed by the heat of the Stomach, and the Heat of these mixt Bodies is called forth; which doth work more freely and strongly, (the friendship it had with the rest of the Qualities being now broke) no longer as the heat of a mixt Body, but rather as heat now separated, and left to its own Liberty.

And the Cause is the same, why things putrifying become at first more moist, and at last are quite dried up. For the moisture together with the heat vapors out, flows abroad, and goes to the outward parts; Which at last being quite dissipated and evaporated, the mixt Body turns to Dust and Ashes. Also hence a Reason may be given why mixt Bodies in hot Seasons and places do sooner putrifie then in cold; and why things very hot or very cold do not easily putrifie. The Cause of the former is, that in cold times and places the heat of the Ambient (if any remain therein.) is not so strong as to be able to cal out the internal heat: but in an hot time and place the Contrary happens. And the Reason of the latter is, because both a strong internal cold resists the heat of the Ambient, so that it cannot corrupt and cal out the inbred heat; and a strong internal heat doth not suffer it self to be overcome by the heat external. Nor can an external weak heat so intend an internal strong one, that it can be no longer fit to conserve the mixt Body. Hence also a great Quantity is less apt to putrifie then a smal one; because in a great Body there is more heat or cold, which also doth more strongly resist the external heat. Also a thing moved doth not so easily putrifie, as that which rests, because it is less subject to the action of the ambient heat.

Why mixt bodies sooner putrifie in hot seasons and places.

Why things very cold or hot do not so easily putrifie.

Why a great Quantity is less apt to putrifie then a smal one, and that which is in motion then that which rests.

Now from what hath been said the Nature of putrefaction is sufficiently apparent: and yet many dispute at large, whether it be only one, or there be divers sorts thereof. We, omitting tedious disputes, do acknowledg only *one* putrefaction, viz. That which is explained, in the foresaid definition of *Aristotle*. Yet we grant there is some diversity in the putrefaction of things, because of the Various Nature and constitution of the mixt Bodies which putrefie. For those things do perfectly and totally putrefie, which are perfectly resolved into the Elements whereof they were made, so that all the other Elements evaporating, there remains nothing at last but Earth: and thus all those things putrefie which have much Earth in them.

There is only one putrifaction.

But those things putrifie imperfectly and in part, which contain more moisture in them. For seeing the moisture which is more abundant in them cannot be with the heat totally drawn out: only some parts thereof, especially the more thin and subtile are drawn out, and the rest are preserved; and this is termed putrefaction according to part; the Nature whereof is nevertheless the same with that of the putrifaction before defined. For herein the internal heat is corrupted by the external. After this manner Wine putrifies, and the Humor in our Bodies; the three Elements, Air, Water, Earth, inasmuch as they are not pure, but in some measure mixt with other things. The Fire alone does not putrifie, for this Cause especially, because nothing is more hot then it, which may corrupt and cal out its heat. But whether or no in this imperfect putrefaction the form of the mixt Body do quite perish, and a new mixt thing be produced, or whether only some alteration be made, is a doubtful case. We answer briefly: in every true putrefaction somwhat is corrupted: but of an imperfect putrefaction there are more degrees,

The Fire doth not putrifie.

Whether the form be abolished in putrifaction.

one

one greater another leſs. For ſomtimes the putrifaction is ſo light, that ſome particles only being corrupted, the mixt Body doth ſtil retain its proper form: but ſomtimes again it is ſo great, that though the whole mixt Body be not quite reſolved into its Elements, yet the whole form thereof is aboliſhed, and the ſaid Body changed into another ſort. And therefore al Putrefaction is Corruption, and not Alteration only. For although the Blood which putrifies in the Veins, is not wholly corrupted, but only altered in part: yet thoſe parts which are ſaid to putrifie, are really corrupted according to their ſubſtance, and cannot return to their Natural ſtate, but muſt be evacuated by Purgation: but the others which are not corrupted in their ſubſtance, are not properly ſaid to putrifie, but only to be heated by the putrified parts.

Chap. 4. *Of Temperament and Coction.*

HAving treated hitherto of the Elements, their mutual action and paſſion, and the Generation and Corruption of mixt Bodies: before we come to the ſorts themſelves of mixt Bodies, we muſt add ſome things concerning temperament and Coction.

As for what concerns temperament, certain it is that it depends upon the mixture of the Elements, and ariſes from the action and paſſion of the firſt qualities: yet what it is, is not ſo manifeſt. We, omitting the opinions of *Fuchſius* who not rightly aſſerts in the 1 *of his Inſt. Med. S.* 3. *C.* 2. That a Temperament is a ſubſtance, not an accident, and of others who hold that a Temperament is a bare Relation and Harmony of Qualities, as alſo of others, which are by other Authors reckoned up; we hold, that *a Temperament is one Quality, ariſing from the mutual action and paſſion of the firſt Qualities in mixtion.* For the fight of the firſt Qualities, which is neceſſary to the Generation of a mixt Body proceeds ſo far, till they be all refracted and abated, and having caſt away certain degrees of Contrarieties, by which they were at extream variance, Friendſhip being made, as it were, they joyn and grow together into one Quality. And ſo a temperament is nothing elſe but one Quality of a ſimple Eſſence, which is made up of the remiſs degrees of the four Qualities. For as of the remiſs degrees of the Elementary forms one ſimple actual form doth ariſe, which nevertheleſs contains them all in its faculty: ſo out of the firſt Qualities there ariſes one moderate and actually ſimple Quality which potentially contains them all. But we muſt not ſay (which opinion as ſome learned men tell us, is ill fathered upon *Avicenna*) that a Temperament is a certain fift Quality, diverſe from the four firſt, and ſuperadded to them; but only a middle one, ariſing from the others abated and conjoyned, and containing them in it.

Whence temperament depends?

But ſince the Elements are in ſundry manners mixed, and the firſt qualities are tempered together in ſundry proportions; hence there ariſe ſundry differences of temperaments. For if the Elements and Qualities concur to the mixture in ſtrength and degrees perfectly equal, a temperament is effected, which is called *Equale ad pondus*, Equal in weight; as if in it the degrees of the Qualities were weighed and diſtributed in an equal weight; alſo abſolute equality, becauſe comparíſon is not made to any extrinſecal thing. Now this is to be underſtood of the equality of degrees. For the Elements cannot be mixed in equal Quantity; ſince the efficacy of Fire is much greater then that of Earth; and therefore if they ſhould concur in equal portions, the Fire would not generate a mixt Body, but only Fire: and experience teſtifies, that all perfectly mixt Bodies do obtaine very much Earth, by Virtue whereof they become heavy. Though ſome deny that this temper is to be found in Nature; yet we ſee no firme Reaſon to hinder us from holding, that the contrary qualities may meet in the ſame degree, to the conſtitution of a mixt Body. Yea and *Galen* ſaies that this is the Rule of all the reſt, and that the reſt cannot be known without it, *in his B. de Temperam. C.* 3.

The differences of temperaments.

Temperament ad pondus, what it is?

Whether there be an equal temperament.

A temperament equal according to justice, what it is?

There is moreover as yet another equal temperament, which is called equal *ad Justitiam*, wherein the qualities concur, not in a degree absolutely equal, but in such a manner as is most convenient to the form of the mixt bodie and to the performance of its generations, and which holds a medium amongst mixt bodies of the same sort. For one mixt body of its own Nature is hotter, another colder; one moister another dryer. The temperament of a Lion is more hot then the temperament of a Fish; flesh is hotter then a nerve; a bone dryer then flesh. And although in this manner this tempertment may be called equal, *viz.* because that equality is kept therein, which is convenient to every mixt body, and according to Geometrical proportion every one hath his own: yet in respect of a temperament absolutely temperate and equal, it is termed unequal; and that body furnished therewith may be termed intemperate: although commonly that is called intemperate which is departed from the temper which Naturaly it ought to have.

Eight sorts of temperaments equal in respect of justice.

Now how many sorts there are of this temperament Authors agree not. We hold with *Galen*, 1 *de temp. C.* 8. For when only one quality superabounds, and overcomes its contrary, the two rest keep equality; for examples sake, if any mixt body should have five degrees of Heat, and three of cold, and four of moisture, and as many of dry; it should be called a simple temperament. Of which there are four sorts; hot, wherein heat exceeds cold, and moisture and dryness are equal; cold, wherein cold exceeds heat, and moisture and dryness are also equal; moist, wherein moisture exceeds dryness, and heat and cold are equal; dry, wherein drineſs exceeds moisture, and Heat and cold are also equal. But when two Qualities exceed the other two, 'tis called a compound Temperament; of which there are againe four sorts, according to the four possible combinations of the four first Qualities; *viz.* Hot and moist; hot and drie; cold and moist; cold and drie. According to these differences a thing is said to be temperate or intemperate: but after several manners. For a thing is said to be so and so, absolutely or respectively. Absolutely only the Elements are hot, cold, moist, drie; seeing in them only these qualitiesare sincere and pure. Now by comparison and exsuperance a thing is said to be so, which though it have all the Qualities, yet one excells the rest; so that is termed hot which hath more heat; and that cold, which hath more coldness. Now this comparison is made to four things; either to the universal Nature of all mixt bodies, wherein if you can conceive any thing of an indifferent temper, such as is the skin of a man, especially that on the palms of his hands and the tops of his fingers, (unto which therefore they refer the judgement of all temperaments;) all other things in respect thereunto will be called intemperate, and according to the Quality exceeding this Mean, they shall be called hot, cold, moist, drie; Or the comparison is made to the next kind; as if in the whole kind of Living Creatures you shall conceive some one to be temperate, as perhaps Man is; all other animals shall be called intemperate, the name being borrowed from the exceeding Quality: or comparison is made to somewhat Indifferent, in the same sort; so a young man is said to be hot, and an old man to be cold: or finally, comparison is made betwixt divers sorts, or any obvious individualls. So a dog, in respect of a Lion is cold, in respect of a Fish hot. So *Peter* compared to *Paul* is hot: but if you compare him to another more hot, he is cold.

How many waies a thing is said to be temperate, and not temperate

And this may suffice to have said in this place concerning temperaments: let us proceed now to concoction, which is a certain perfection and compleatment of the temperament. Now thus *Aristotle* (in his 4 *Meteor. Ch.* 2.) Defines concoction. *Concoction is a perfection, by the Natural & proper Heat, made of opposite passives, which are the proper matter to each one.* This definition as every orderly definition of adjuncts or accidents, hath in stead of kind the form, in stead of difference the subject, with the efficient cause: all which are to be considered in this place, that we may attain the perfect knowledg of Digestion or Concoction.

The definition of concoction

The form of concoction.

The Form of Concoction is nothing but the ultimate perfection of the proper temperament of a thing. For then a thing is said to be concocted, when it hath attained that perfection and compleatness, in its qualities or temperament, which it ought to have. And therefore that perfection is here to be understood which consists in Qualities, and not that which is Essential, proceeding from the substantial form. Which also *Aristotle* signifies *in the* 12. *Sect. Prob.* 7. *Concoction is the alteration of the thing concocted.*

The matter or subject of concoction are the two passive Qualities, but especialy moisture. And hence it appears, that coction is an affection of a mixt bodie, as it is moist, and that it doth not belong only to the meat of living Creatures, because other things also are said to be concocted, which can never become nourishment for animals. Hence also t'is manifest, that coction belongs to a thing already engendred and constituted by its own Nature. For nothing is said to be concocted, but that which is already engendred, only it hath imperfection in its temper, which must by further alteration be perfected; which being done the thing is said to be concocted. *The Subject.*

As to the Efficient Cause: *The beginning of perfection* (saith *Aristotle*) *comes from the proper heat of the subject, although it be perfected by some outward help.* The principal cause is alwaies the proper heat of the thing; although sometimes it be not sufficient, and therefore stands in need as it were of another Assistant, that the concoction may be thereby better and more rightly performed. So Bathes and Plaisters help the Concoction in the Stomack. So Medlars and other Fruits being gathered before they are ripe and laid up, are ripened by their own Heat: yet the Suns Heat contributes much towards their more happy ripening. *The Efficient Cause.*

This therefore is the manner of the whole business of concoction. When as in a mixt body, already constituted by its form, there is as yet some imperfection in the temperament, and the moisture is not sufficiently mastered and tempered, nor holds a just and exact proportion to the drines and other Qualities: the Natural Heat consumes and excels the superfluous moisture, and that which remains and offends not in quantity, it restrains and limits, and unites it with drines, as much as the Nature of the mixt Body requires; which action is termed coction, or concoction. *The Manner of coction.*

And that the Nature of concoction may be the better understood, *Aristotle* besides the internal End, which is the same with the form, adds also an External one, in these words: *The end of concoction in some things is their Nature, which we call the sort as it were & Essence; in others it tends to some subject forme, when the Humidity is become such and so great.* In which *Aristotle* Teaches, that the External End is twofold; either the form simply and absolutely, which End chiefly appears in the ripening of Fruits, which are then said to be ripe, when the seed is now so perfect, as that it can breed its like: or some form or disposition, to the affording some utility, which consists either in the induction of a new form, or in preparation for the convenient expulsion of things unprofitable. The former use appears in that boiling of the meat, performed in the stomack. For that is therefore ordained, that the meats taken in might by the faculty in the stomach be turned into *chylus*. For such also is the Natural Concoction of flegm. The other appears in the Concoction of putrified humors in ulcers, and elsewhere in the Body of an Animal, which are then concocted and ripened, when they are so laboured by the Natural Heat, as to become apt for expulsion. For since by reason of their great corruption they cannot arrive to any perfect form and profitable to nourish the Body, they are by concoction brought to some form better at least then putrefaction. And thus Concoction doth repress Putrefaction, and puts an End thereunto, and severs the corrupt humors from the profitable, and renders them fit to be euacuated without hurt to the Body. *The External End.*

Things therefore are said to be concocted, when the matter of coction, which is chiefly moisture, shal be overcome by heat and bounded thereby, and have received it's fitting thickness. And therefore Urines, Dung, and all the excrements of our Bodies in like manner, being rightly digested, are a signe of Health. For they declare that the Heat hath its full power in our Bodies: and that it is so much as to be able to restraine and duly to tame and keep in order all the humors. And for the same Cause, all things being digested become thicker and hotter. For Heat which bears the Rule in concoction, doth both Heat and Resolve the thin Parts. Which is also confirmed by Experience. For Apples, Pears, Grapes, and all other Fruits, before they grow Ripe are colder then they are afterwards: and Milk, Seed, Quittour in Ulcers, and Filth gathered in the corners of the Eyes, are thicker when concocted then before. Howbeit, we must here take notice, when it is said, that things Concocted are thicker and hotter then Unconcocted, that one thing must not be compared with another of a distinct sort, or with it self after it hath changed its *species*; but the same sort of thing being unconcocted, must be compared with it self concocted.

To

The definition of Crudity. To Coction is opposed Crudity, or indigestion, which is by *Aristotle* in 4. *Meteor.* thus defined: *Crudity is an imperfection of the passive Qualities, through the defect of proper heat in the subject. And the defect of heat is cold.* From which definition it is apparent, that in Crudity all things are quite contrary to what they are in Coction, saving the subject, which is one and the same. For the Form was there perfection, and here it is imperfection; there the efficient Cause was heat, here want of heat, or Coldness. And therefore those things are generally to be called Crude, which have not as yet obtained those degrees of perfection in the Qualities or Temperament, which they ought to have; and in which moisture abounds, and by reason of the weakness of Heat cannot be rightly mastered and Limited.

Coction is not an univocal kind. Having explained the Nature of Coction and Crudity, let us now come to their Sorts. Where it is first to be observed; That Coction is not an univocal kind, but of the number of those which are called *Pros Hen*, to one, and that therefore its definition doth chiefly agree to the principal and primary sort (which is the manner in defining those things which are said of some one) but a little change being made, they may also be accommodated to the rest. Now the primary sort of Coction, and which can perhaps alone perfectly bear the name of Coction, is ripening, which it self also nevertheless is not equally applied to all the sorts contained there under. For properly *Ripening is the Concoction of that Aliment which is in the Pulp of an Apple, Pear, or any other fruit.* But for more easie understanding sake, *Aristotle* applies Maturity, or Ripeness, only to fruits; though it be common to all Animals, Plants, and Seeds when referred to Generation. Now then Maturation is said to be made, when the Seed which is contained in the Pulp of the fruit is so Elaborated, that it is able to beget its like. For at first, when there is as yet a superfluous moisture remaining, the Seed is not yet fit for Generation: but when the humidity shall by the Natural Heat be partly consumed, partly better terminated, the Seed becomes fit for Generation. Again, Figuratively, Flegm, quittor, and other Humors in our Bodies are said to be Ripened, when they are by the Natural Heat so digested, as either to become fit to nourish, or if they cannot nourish, that at least they may be disposed to Evacuation. Now, by ripening, flatulent things become Watry, Watry things become thin; thin things become thick. For at first the spirit, or flatulent matter is digested by heat; afterwards, the Watry Humor is further digested, and its thinner parts are resolved.

Ripening what it is?

What immaturity is? To Maturity or Ripeness is opposed Immaturity or Unripeness, which as Maturity is also twofold: one properly so called, another figuratively. For immaturity properly so called is the rawness of the nourishment which is in the Pulp of an Apple or other fruit, by Reason of the Penury or ill proportion of the Natural heat. For when the Heat is so little, or the Humor so plentiful, that the Heat cannot exactly master the moisture, there arises immaturity, and then the Seed is not fit for Generation. And therefore all unripe things are windy, watterish, and their Humors thin and cold, unfit to nourish. And afterward Figuratively, Catarrhs, Spittle, Quittor in Ulcers, and Urin are termed crude. Also Milk unboiled is termed crude or raw; as also Tiles and all Earthen Ware, is termed raw, before it is baked.

Another sort of Coction is *Boyling*, which *Aristotle* in the *fourth of his Meteors Ch.* 3. thus defines: *Elixation or Boyling, Generally, is the Concoction of somwhat Indeterminate in an Humor, caused by a moist heat.* For boyling is thus made. A fiery heat being received in a Watry moisture, doth moisten the thing to be boyled, opens its pores, and makes them Wider, and so draws the moisture of the thing to be boyled from the Centre to the Circumference; and the rest of the Humor which remains, it digests, Tames, and Terminates; and therefore boyled things have less Native moisture, and more of that which is forreigne. And for this cause, Cooks that would Roast Meats carefully, do first perboyl them, *viz.* that some of that Humor and Excrements which are within, may be first drawn out, so that the rest may be by roasting more easily consumed.

From the premises it appears, that those things only can be boyled which have moisture, which by the fiery heat which is in a Watry moisture may be overcome. And that those things cannot be boyled, which either are Earthy, and have in a manner

manner no moisture, as Stones, Bones, &c. Or which have indeed some moisture, but which is so condensed and Joyned with an Earthy dryness, that by a moist heat it cannot be called out and Vanquished, as Woods, Metals, &c. And for this very cause, the flesh of old Animals is hardly boyled tender, in comparison of yonger; and Beef is harder to boyl then Hens-flesh: because the former are more dry, Earthy, solid and compact, and have their moisture more tenaciously fastened with their dryness, so that it cannot easily be called out by a moist heat. Also Woods, Metals &c. though improperly, are said to be boyled. For though they are not so softned as things really Boylable: yet some of their moisture is drawn forth, and communicated to the Water; which, the tast the Water receives by their boyling in it, doth witness. Also boyling is attributed to a moist Body that hath little dryness in it, as to milk, new Wine or Must, and other things, *viz.* When by boyling some parts of them do vapor away, and the remaining parts do receive some change in their temperament and tast.

To boyling is opposed imperfect boyling, which is called *Inquinatio* and *Flaciditas*, which is defined by *Aristotle* to be, *The Inconcoction of that which is undetermined in a Body, by Reason of want of Heat in the moist thing which compasseth the same about.* For this Inquination or Flaccidity, is properly nothing else but a boyling begun, *viz.* when the Heat which is in the Watry moisture is indeed so great, that it can in some measure act upon the thing to be boyled: but is not so strong, that it can perfectly Boyl the same, but either by cold or overmuch moisture in the thing to be Boyled it is blunted and overcome, that it cannot perfect its work: which kind of imperfect Concoction oft happens in Aged and Sick People, whose Heat doth in some manner alter the meats, but cannot perfectly digest them. *Imperfect boyling, what?*

The last sort of Concoction, is *Optesis*, roasting; *Which is a Concoction caused by a dry external Heat.* For if in a mixt body the abounding humor be consumed and tempered by a dry external Heat it is called a Roasting. Now roast meats are without indeed dry, but within moist with a moisture of their own, and more moist then boild meats themselves. For the dry heat withers the external parts, and straitens the pores, that the internal Humor can find no way out. Now roasting and boyling are chiefly caused by Art, and these names do chiefly belong to them, as being becaus Artificial best known to us. Yet the same things are also done by Nature. For the Concoction of Aliments in the bodies of Living Creatures, and especially that in the Stomach, is boyling: also the same may not unfitly, in Hot and Dry Bodies, be called roasting. *Roasting what?*

To roasting also is opposed Semiustulation, Toasting, or raw-roasting. Now bad roasting is caused through want of heat, which either is little of it self, or not so great that it can possibly overcome a great aboundance of Humor, and therefore it perfects not the begun roasting. *And so much touching Concoctions.* *Raw-Roasting.*

THE

THE FOURTH BOOK.

Chap. 1. *Of Meteors in General.*

Mixt Bodies twofold.

HAving spoken hitherto in General of the Elements the principles of Natural Bodies, and their mixture; of the Generation of Natural Bodies and their corruption: order therefore requires, that we should now treat of the several sorts of Natural Bodies. And seeing that mixt Bodies are twofold, perfectly and imperfectly mixed; and the imperfectly mixt are the Meteors: we must now come to that part of Natural Philosophy, which all the Ancients (as *Aristotle* in his 1. *B. Meteor. C.* 1. *tells us*) called *Meteorologia*, the Doctrine of Meteors.

Later writers do here indeed raise a scruple, and some deny that a Body imperfectly mixed and a Meteor are one and the same thing; and they say the name of Meteor is of a larger extent, since there are many Meteors which are not Bodies, such as those things which happen only as an apparition as Thunder, Lightning, Earthquakes: others again conceive that the term Meteor is only to be given to bodies imperfectly mixed, and therefore they exclude those things as Thunder &c. which have no subsistency, out of the Number of Meteors; since all things which make up the subject of Natural Physosophy, and are parts thereof, must be in the number of Natural Bodies. But this Controversie may easily be composed. A Body imperfectly mixed must be somewhere explained in Natural Physosophy, and indeed most fitly next after the Elements: and therefore tis said to be the subject of that part of Natural Physosophy. And seeing the same affords matter for Meteors, that part of Natural Physosophy is called *Meteorologia*, the Doctrine of Meteors. For though in it are also explained those things which are not Natural Bodies, as hath been said; yet those very things are either the Adjuncts or Effects of Bodies imperfectly mixed. Hence use hath obtained, that under the term Meteor, both Bodies imperfectly mixed and their Adjuncts and Effects should be comprehended.

A Meteor what it is?

And so the subject of this Doctrine is *Meteoron* a Meteor, that is, *Somwhat raised out of the Earth and Water by force of the Stars and the under-ground Fire, and bred for the most part aloft in the Air.* For the word *Meteoron* in general doth signifie a thing sublime, Elevated, and hanging as it were up on high.

And by aloft or on high we understand, not the Heaven, but all that space which reaches from Earth to Heaven, which place is called upwards, or above. Yea and since *Meteoron* signifies somwhat Elevated and suspended on high, even those thing also which are made in the Caverns of the Earth, of exhalations there raised up, are comprehended under this Name. For all things contained under this name are not of one kind, as hath been said before. Hence some divide them into Hypostatical and Emphatical. They are most conveniently distinguished into three Ranks. For either the Nature of a Meteor consists in the changing of an exhalation into some other thing, which happens in fiery Meteors, Rain and such like; or in motion, as in Winds, Earth-quakes; or in the Reflexion of Beams, as in the Rain-bow.

The Difference of Meteors.

The Efficient cause of meteors

Most do hold the efficient Cause to be Heaven, and the Heaven and the Sun are the chief cause which raises exhalations: but they are not the only cause, but heat also

alſo concurs and the ſubterranean fire; and in the Generation of Metals and Minerals many exhalations are raiſed, as is known to thoſe that ſearch after Metals; and Winds and other Meteors are bred no leſs in the Winter, when the Sun beams are weak, then in the Summer.

The matter The remote matter, are not only the four Elements, eſpecially the Earth and Water, but alſo mixt Bodies, out of which oppoſite exhalations are wont to be raiſed. The immediate matter is a twofold kind of exhalation, raiſed out of them being heated. For the Heavenly Bodies, eſpecially the Sun, and the Subterranean heat do excite and raiſe up a twofold kind of Exhalations: whereof the one which is termed *Atmis*, that is a vapor, is hot and moiſt, raiſed out of the Water or moiſt ground, being of as it were a middle Nature betwixt the water and Air, ſo that it may eaſily be changed into either Element. For it is moiſt in the higheſt degree, but heat is therein remiſs, and ſome degrees of coldneſs, or portions of Water carried up therewith, do remaine in it; and as *Ariſtotle* ſaies in the 1 *Met. Ch.* 3. A Vapor is as it were potentially a Water. But the other Exhalation is called a Fume, or a Smoaky Exhalation; and it is Hot and Dry, raiſed out of the Earth, and eſpecially the drier parts thereof, heated and attenuated by force of the ſtars; of a middle Nature as it were betwixt Fire and Earth. For this Exhalation is exceeding dry, and moderately hot; for it retains ſome degrees of the Earths coldneſs, or rather ſome parts of the Earth it ſelf Elevated with it. And therefore *Ariſtotle* in the ſame place ſaies, that this Fume is potentially, as it were, Fire. Now there are chiefly two ſorts of Fumes, the one of which is termed *Ecphlogoſis* a flaming Fume, which is raiſed out of a Fat matter and is apt to take flame: another which is raiſed out of drier ground, and doth not ſo eaſily take Fire, but rather turns to Winds and Blaſts. Theſe two kinds of Exhalations though they are of a diſtinct Nature, and both in reſpect of their Heat, drineſs, Levity and Original differ one from another; (becauſe a vapor is Cold, Heavy, Moiſt, raiſed out of the Water; but a Fume, Hot, Light, Dry, raiſed out of the Earth:) yet for the moſt part they are bred joyntly, and both together, Becauſe in moſt places the Earth is mixed with Water: whereupon that which of its own Nature is Heavy, by help of the other lighter, is lifted up and raiſed on high; although when they come to the middle Region of the Air they are ſeparated, and the Fume is raiſed higher, but the vapor ſettles beneath. And theſe two Exhalations as they are commonly called are the matter of all Meteors; whence alſo it is that they are called Bodies imperfectly mixed; either becauſe they do not conſiſt of all the Elements, or becauſe in them the forms of the Elements are kept perfect and intire, and do not incorporate into the form of one mixt Body. For which Cauſe alſo ſuch kind of Bodies cannot long laſt. Yet it is wont many times to happen, that Atomes alſo of bodies perfectly mixed are mixed with theſe Exhalations; yet ſo as that theſe Exhalations are not informed by the forms of perfectly mixt Bodies, but only touch the ſaid mixt Bodies.

The Place. The place where Meteors are ingendred is chiefly the *Air*. For it according to the divers Regions whereinto we have ſhewed it is divided, doth afford place to divers Meteors, as we ſhall afterwards declare. For even thoſe alſo which are ſaid to be ingendred in the Earth, are properly ingendred in the Aire contained in the caverns of the Earth. Howbeit in the Sphere of Fire, and eſpecially in the Loweſt part thereof, it muſt not be denied, but that Fiery Meteors are generated. Alſo upon theſe, *viz.* the place and matter, depends the chief diſtinction of Meteors. For ſome conſiſt of an Exhalation, others of a vapor: ſome are produced in the upper, others in the lower Region of the Air. We ſhal begin with thoſe which ariſe from an Exhalation, and among them with thoſe which are commonly termed fiery and inflamed Meteors.

Chap. 2. *Of Fiery Meteors.*

THe greateſt part of fiery Meteors are bred in the upmoſt Region of the Air. For when Hot and Dry Exhalations do aſcend thither and are there inflamed, ſundry fiery Meteors are ingendred, which differ according to the various diſpoſition of the matter, the diverſity of inflammation, their magnitude, Figure, Motion and

Duration: of which though peradventure more sorts might be reckoned up, whose Names are borrowed from the shapes which they represent in their burnings, yet I shall recount the chiefest of them. Now many reckon the *Via Lactea* and Comets amongst fiery Meteors, but of them we have spoken before.

Also very many fiery Meteors do arise, differing only in the posture of the matter, the multitude and shape they represent whiles they burn; which also are to be explained. And that we may begin here: if an Hot and Dry Exhalation, not very thick and Fat, but subtile, stretched out in length and breadth, do take fire in the upper Region of the Air, there appears a burning and shining *Flame*; sometimes with so much brightness, that it doth a little dispel the darkness of the night. Some cal this Meteor, *Burning stubble*, for it represents heaps of stubble suddenly set on Fire.

A burning flame how ingendred.

Skipping Goats. *Skipping Goats* so called, do appear, when the Exhalation is drawn out in length rather then in bredth, having parts not equally disposed, or distinct Masses, Joyned together by thin and rare Exhalations; or they have on the sides certain threds as it were and bristles annexed. For when this is inflamed, the Fire suddenly leaps, either out of the subtile and thin part of the Exhalation into another part thereof; or it runs out into the sides and those Bristles or Appendixes aforesaid, and by and by runs back again; and so it seems to dance, like Goats wantonly Skipping.

Burning brands. Burning Brands are, when the exhalation is drawn out in like manner, rather in length then breadth, having its parts nevertheless equally disposed For if this be set on Fire, it represents a burning Fire-brand or Beam. And these Beams do not move to and fro as Links or Torches, but are quiet, and shine in one and the same place. The *burning Lance or Dart* commonly so called, seems to be the same Meteor with the former. For by these Names a Meteor is designed, which is bred of an Exhalation or Fume, drawn out at length, and having parts of equal thickness, which being set on Fire doth burn all together, and shews the image of a Dart or spear. Nor doth the Perpendicular or Pyramidal Fire, so called, differ much from this, being ingendred of an Exhalation drawn out in Length, and Lighter in its upper part, Heavier in its lower. For being set on Fire in its upper and lighter part, it represents a Pillar set bolt upright; and its lower and heavier part resembles the Basis thereof. Like unto this is the *burning Candle or Torch*, Which consists also of a dry Exhalation, drawn out in length alone, and equally thick. For this being inflamed at one end, and in some measure shining upon the other part not inflamed, it represents a burning Candle or Torch.

A burning Spear or Dart.

The burning Pillar

The Candle or Torch.

Shooting Stars. *Running Stars*, as *Pliny* in the 2. of his Natural History, Cap. 37. calls them: the *Coursing of Stars* (as *Seneca* Phrazes it, in the 1. *Book of his Nat. Quest. Ch.* 14.) Flying Stars as some cal them, and falling or shooting Stars, because they appear in the shape of falling or flying Stars, do happen two manner of waies. First of all when an exhalation in the upmost Region of the Air, drawn out in length, is torn, distinguished and spred abroad into many particles as it were. For the first part being inflamed doth speedily communicate the Fire to the other, the Second to the Third, the Third to the Fourth, &c. After the same manner as one Candle lighted doth easily light again another newly blown out; and so it makes shew of a shooting Star. Again, when an Exhalation subsists in the middle Region of the Air, and either by Antiperistasis of the cold Air is inflamed, made lighter and so raised on high, and shews like a flying Star; or being by the coldness of a cloud compressed and Squeezed, it conceives Fire, and moves downwards, for the most part sidelong, and violently; and then a Star seems to fall from Heaven. Also a third manner may be added, *viz.* When an Exhalation drawn out in length, of equal thickness, and apt to burn, is set on Fire. For this burning all on a sudden, and the flame speedily passing from one part to another, it makes the appearance of a shooting or flying Star. For we must not give credit to the dotage of the *Epicureans*, who taught, that Stars did really fall from Heaven. For, to use the words of *Seneca*, in *L.* 1. *Quest. Nat. Cap.* 1. if this were true, there would have been ere now no Stars left in the Heaven. For there is no Night wherein many shooting Stars appear not. And yet the Stars of Heaven appear in the same place they were in before. They are all as big as before. When many shooting Stars appear, they

they foretell Winds to follow. For they argue ſtore of dry Exhalations which are matter for Winds: whereof *Virgil* in the 1. *Book of his Georgicks or Huſbandry:*

When Stars in Heaven do ſeem to Fall, and make
Through Nights darke Aire, a long and Firie Tracke,
'Tis Sign of Winde.

The flying Dragon.

The *Flying Dragon* is ingendred in the middle Region of the Air. Now this Meteor is made, when an Exhalation not too clammy and hot, meets with a cold Cloud, and is thereby driven back, and ſo either by motion or by *Antiperiſtaſis*, in its upper part, where it is lighter, it is ſet on Fire, and ſeems to vomit Flames and Sparkles; but in its middle part where it is Thicker, and is bowed, it Repreſents a Belly: and in its lower part which is Narrower and Straiter, it Reſembles a Taile.

Willy with the Wiſpe, or Peg with the Lanthorne.

In the loweſt region of the Aire is ingendred the *Ignis fatuus, or Willie with the Wiſpe*, near fat and moiſt ſoiles, pooles, Church-yards, places of Publique Execution where Malefactors are buried, where are ſtore of clammy and fat Exhalations. For they being ſet on Fire, either by *antiperiſtaſis* of the cold Aire of the night, or by motion, do appear like burning candles, and are diverſly moved according to the motion of the Air; and therefore they are called walking lights, and ſometimes they ſeeme to go before a Man, and then again to follow him. For when ſuch as travel in the night would come to theſe Fires, the Air before them being driven by their motion, theſe Fires being alſo moved with the motion of the Air do go along before and fly from them: but when they runſ from the ſaid Fires; the Air behind their backs following them, the Fires do alſo follow. Theſe Fires do many times draw Travellers out of their way, and make them fall into Ditches, Quag-mires, and Rivers: becauſe wayfaring people, ſuppoſing that theſe Fires are Candles ſhining in the next Villages, do make towards them, and leaving the right way fall head-long into the next Rivers and Pooles they come at; Or by theſe Fires being generated about Watry Places, and there ſeeking their Nouriſhment, they are ſeduced into the ſaid Waters. And it is hardly to be denyed, nevertheleſs, but that ſomtimes the fraudulent Illuſions of the Devil doth concur in the Caſe, Who continualy ſtudies the Deſtruction of Man-kind, and ſeeks al occaſons to do harm.

Why when a man followes them, they go from him; and when he runs from them they follow him.

Why they lead Travellers commonly into waters.

Helena, Caſtor, & Pollux.

Alſo of a light Exhalation in the ſame manner are Bred theſe *Meteors* called *Helena, Caſtor and Pollux*, which are wont commonly to be ſeene of *Marirers* at ſea, in the time of a tempeſt: and if two appear, they are called *Caſtor and Pollux*; if one alone, 'tis called *Helena*: and one is counted unlucky, but two a ſigne of faire weather. For ſo *Plinie Lib.* 2. *Nat. Hiſt. C.* 37. *Theſe Stars are of grievous importance, if they come ſingle, and drown the ſhips, and if they fall into the Hole, they burne them up. But if they come two together they are good Signs and tokens of a proſperous voyage, by whoſe coming they ſay the direfull and threatning Helena is chaſed away: and therefore they attribute this Divinity to Caſtor and Pollux*, and ſet their Images on the Ship ſterne as tutelary Deities whom they invoke at Sea; as may be ſeen in the *Acts* of the Apoſtles, *Ch.* 28. *v.* 11. But theſe things are taken rather from Heatheniſh ſuperſtitions then phyſical Cauſes. That appears more true, that when theſe *Meteors* are moved up and down with an unſtable motion, they foreſhew Winds and Tempeſts; and when in the time of a Tempeſt they fall down into the Ships, or ſtick to the Maſts, they are a ſign of faire wether and a Calme. For now they ſignifie that the blaſts of the Winds and the Tempeſts do abate. Howbeit concerning the Star *Helena*, thus *Cardan* writes *in his* 2 *B. of Subtilties P.* 69. Of the ſame kind wellnear is the Star of *Helen* about the Maſt of a Ship, which when it falls melts even Braſs-Kettles, and is a certain Sign of Ship-wrack. For it happens only in grievous Tempeſts, and it cannot but Breed in a moſt groſs Aire, nor be gathered in the Ship ſave by great force of Winds, ſo as to be ſet on Fire, and therefore it portends immediate Deſtruction. The ſame *Author* in the ſame plece, endeavourrs to ſhew a Reaſon why theſe Stars appearing double promiſe ſafety to the *Saylors*, howbeit 'tis ſcarce of any moment.

Fire cleaving to the Haires or Garments of men.

Hitherto also pertains the Fire which is somtimes seene on Mens hairs, and Garments, and on the Hairs of other Creatures, and upon other Things. This arises from a Subtile and Fat Exhalation, dispersed through the Air, and sticking to the Haires or Clothes of Men, or out of the sweats of Animals of an hot Constitution, or heated with vehement Motion, set on Fire by *Antiperistasis*, or by violent Motion. some such thing happened to *Ascanius*, of which *Virgil in the 2 of his Æneids.*

Hexameter verses.

See o'th top of Iulius *Head a glistering Lustre,*
And all about his Locks a Flame, without any burning.

Livie Relates such a like thing of *Servius Tullius*, *Lib.* 1. *Dec.* 1. And *Valerius Maximus*, *Lib.* 1. *Cap.* 6. Also *Livie* writes in *his* 3. *Decad. Lib.* 5. That when *Lucius Martius* was making an Oration a Flame sprung out of his Head, which he felt not, and begot him great Favour among the Soldiers standing about. Most are of Opinion that these Fires do signifie the breaking out of some great Honor or Dishonor, and that they have been alwaies taken as signs of good or bad Luck, as the Histories and Examples aforesaid do testifie. And therefore some deny that they are alwaies to be referred to Natural Causes. That is a Remarkable Passage related by *Cardan*; that a Certain Man came home to his House after one a Clock in the Night, and when he put off his Cloake, a Sparkle flew from the Cape thereof; and when he tooke his Cloake againe and laid it off, it Sparkled againe, so that he was double affrighted; and within 15 Daies he was by his Enemies accused of Witch-craft, and sought for, to be tormented and punished: but by the advice of his Friends He underwent a voluntary banishment.

How thunder is Caused.

Also from the same dry Exhalation *Thunder Lightning and Thunder-bolts* do arise. Touching *Thunder* there are sundry Opinons of the Ancients, as we may see in *Aristotle*, L. 2. *Meteor. C.* 9. Plutarch *de placit. Phylosoph. Lib.* 3. *Cap.* 3. Seneca *in Quæst. nat. Lib.* 2. *Cap.* 17. 18. &c. Lucretius. *Lib.* 6. Nor are late writers of the same judgement concerning the same. For *Bodinus* conceives that Thunder and most other Meteors, do not arise from Natural Causes, but rather from the Power of God, or the Divel. *Aristotle*, whose Opinion is thought to be more probable then the Rest, doth conceive that Thunders are thus generated: When a twofold Exhalation hot and drie, is raised together, and thickned into a round Cloud in the middle Region of the Air: and the Cloud being thickned by Reason of the coldnes of the place, nespecially in the upper part thereof, and the hot Exhalation being shut up therein, and besieged on all sides by the cold, it fights with the cold, and seeking an egress, it runs this way and that way, shaking the sides thereof; or also breaking through the same it makes that noise which we call Thunder. An Example whereof is seen in Guns; when the fiery spirit, proceeding from the Coale-Sulphury Nitre, (to use the words of *Scaliger* in *Exercitat.* 11. *Sect.* I.) cannot be contained in the Room it was in when it was Gun powder, it violently seeks its passage, and suddenly breaks out, making a noise like Thunder. Which happens also in Wood and Chest-Nuts, when they are put into the Fire, containing in them a hot Expiration. For the said Exhalation being rarified, and not finding a place to containe it self, it breaks out of the wood and Chestnuts with a Noise.

Chymical operations declare the generation of thunder

Howbeit Chymical Operations do afford light to this Doctrine, which do not only declare the Cause of Thunder more particularly & clearly; but also shew that the aforesaid Noise is caused not only by the matter shut up and seeking an Egress, but also by the sudden breaking of the Air, caused by the Motion of Bodies, mutually abhorring and flying one from another. For by the aforesaid Operations it is easie to see, that as oft as a part of inflamed Sulphur is added to Nitre, a mighty Noise is Caused. Which also is to be seen in Gun-powder, and in that Preparation of Nitre, which they call *Sal Prunelæ*. Nor doth the common Sulphur only worke this Effect: but the Sulphur also of Minerals and Metals, when Nitre is added thereto, as appears in the Calcination of Antimony with Nitre: but especially in *Aurum Fulminans*, or Thundering Gold, so called, which being set on Fire, strikes with greater force and Noise then Gun-powder, only it moves downwards. Nor is it unknown, that of Nitre, Sulphur, Quick Lime, and Bitumen mixtures

are

are made, which being ſprinkled with moiſture, or wet with ſpittle only, are ſet on fire. Now that force depends not on Sulphure alone, or Nitre alone, but on both mixed together. Sulphur indeed quickly takes flame, but burns ſlowly: but Nitre is not eaſily inflamed, but being once ſet on Fire, it burns quickly away and in a moment as it were. And therefore it is from Sulphur that Gun-powder ſo ſoon takes Fire; but that it burns up ſo ſuddenly proceeds from Nitre, and all the force thereof proceeds from the ſaid Nitre. From whence it is not hard to judg of the Generation of Thunder. For when in the Summer time Sulphurous and Nitrous Vapors are inviſibly raiſed up by the heat of the Sun, eſpecially when the South-winds blow; and afterwards either by the oppoſite Winds, or by the coldneſs of the middle Region they are united and condenſed, it comes to paſs, that they are there inflamed, and hence proceeds the Thunder and Lightning.

Thunder may alſo be made without Clouds

Whence it appears, that it is not altogether untrue, that Thunder or ſomwhat like it may be alſo made without clouds. For Hiſtories witneſs that Thunders have been heard the Sky being clear: and *Pliny* relates *Lib.* 2. *Cap.* 51. That there was a man ſmitten with a Thunder Bolt, on a clear day; and other have obſerved the ſame. Which Thunders may wel be thought to have been bred of a ſpirit and a dry Exhalation, contained in the Caverns of the Earth, and breaking out with great violence. Which thing is made more credible by what *Seneca* relates, *Queſt. Nat. Lib.* 2. *C.* 30. after this manner: Once upon a time *Ætna* was ful of fire: it poured forth an Ocean of burning Sand. All the daylight was darkend with duſt, and the People were frighted by the ſuddain approach of night. At the ſame time tis reported there were very many Thundrings and lightnings: which were cauſed by the concourſe of dry bodies, and not of clouds; for it is not credible there were any clouds, the Air being ſo burning hot.

Lightning what it is?

Alſo concerning Lightning there is ſome diverſity of opinions, as may be ſeen out of the places fore alleadged. Moſt retain the Opinion of *Ariſtotle*, who held that Lightning was an hot Exhalation driven out of a cloud, and ſet on Fire chiefly by vehement motion, and caſting forth a ſhining Light.

Why the Lightning is ſeen before the thunder is heard?

And although the Thunder be before or as ſoon as the Lightning, yet the Lightning is ſeen before the Thunder is heard; *viz.* Becauſe the ſight is quicker then the hearing, and viſible repreſentations of things are more ſpiritual, and more fit for ſudden propagation, then audible. An example whereof we have likewiſe in ſuch as cleave Trees in the Woods, where we ſee the blow light, before we hear the ſound. And in Guns, where we Firſt ſee the Fire before we hear the Report.

A thunder bolt.

A Thunder-bolt differs not much from Lightening; for it is an Hot and Dry Exhalation, more compact then Lightning, ſuddenly breaking out of the Clouds with great force and violence. And therefore it is not alwaies diſperſed in the Air, as moſt other fiery Meteors are, but is carried often to the Earth: both becauſe it is darted out of the Cloud with great force and violence, as alſo becauſe it conſiſts of a matter well compact and cleaving together: yet *Pliny* tells us (in his *Nat. Hiſt. Book* 2. *Ch.* 55.) that it never ſinks into the Earth above Five foot. Hence *Seneca* in *Queſt. Nat. Book* 3. *Ch.* 57. *Lightning which only ſhines, and the Thunder-bolt which is darted down, are made after the ſame manner. But the former is of leſs force, and hath leſs nutriment. And to ſay what I think in a word: a Thunder-bolt is Lightning compact and Vigorated.*

The Nature of the thunder-bolt declared from Chymical Principles.

That theſe things may be explained from nearer principles: the Lightning and Thunder-bolt differ only in the diſpoſition and plenty of the Sulphur and Nitre. For the more plentiful and ſubtile the Nitre is; ſo much more vehement is the blow: and becauſe of the aboundance of Sulphur, there is more appearance of fire. Hence a Cauſe may be rendred why it lightens ſomtimes with Thunder and ſomtimes without. For the reaſon hereof is not, becauſe the Cloud is ſpungy or compact, ſomtimes ſtopping the paſſage of the Exhalation, and other whiles giving the ſame a free Egreſs: (for the Clouds are not ſo thick as to be able to ſtop in the Lightning:) but becauſe there is ſomtimes good ſtore of Nitre, otherwhiles but little joyned with the Sulphurous Exhalation; therefore ſomtimes vehement Thunder, other whiles little or none is heard.

The *Thunder-Bolt* therefore is a fiery and thin Nitro-Sulphureous ſpirit, and not a ſtone as the common people imagin. For the wonderful power and force of the

Thunder-

Thunder-bolt, of which we shall speak anon, must not be ascribed to a stone, but to a Body much more thin and subtile. And if any man will hold, that a most solid Stone may sometimes be bred in the Clouds of Exhalations thickned and coagulated, and be cast down with the Thunder-bolt or Lightning as a bullet shot out of a Gun, I shall not contend with him; yet I think such a thing happens but seldom.

I conceive it comes more frequently to pass, that by reason of a Thunder-bolt falling upon the Earth, the same and what ever matter is apt thereto, is melted as it were by Fire, and out of that fluid matter such a stone is formed; since it is otherwise a well known thing, that Iron and other Metals may be suddenly melted with a Thunder-bolt.

The effects of thunder bolts. The Effects of Thunder-bolts are wonderful. For by it Silver hath been melted in mens Purses, and the Purses no way hurt or harmed: the sword hath been melted, the Scabbard remaining intire; all the Iron hath melted and run down a Post, the Wood unhurt; the Bones in live Creatures have been mashed to pieces and the flesh not toucht; and *Martia* a Roman Lady had the Child in her Womb kild with a Thunder-bolt, her self unhurt, as *Pliny* tels us in his *Hist. Nat. B.* 2. *Ch.* 51. In a word the Thunder-bolt hurts all hard and solid things sooner then such as are light and Spungy. The Cause whereof *Aristotle* saies to be (3. *Meteor.*) because it sooner goes through light and Spungy Bodies, then to be able to hurt or burn them. But in such things as are thicker, while it staies a little seeking a passage which it cannot easily find, it doth the more hurt. And why the Hogshead being broken by a Thunder-bolt the Wine stands congealed, the reason is, because the heat of the Thunder-bolt condenses the external parts of the Wine, that the Wine stands congealed and shut up in a Skin as it were. Yet *Seneca* tels us that this stif-standing of the Wine doth not last above three daies, *Quest. Nat. L.* 2. *Cap.* 31. That also is to be noted concerning the wonderful power of a Thunder-bolt, which *Meuererus* relateth in *Com. Meteorol. p.* 140. How that a certain Minister in the way from *Leipsich* to *Toga*, was so suddainly taken out of the sight of all men by a Thunder-bolt, that he was never seen more.

Whether some things are safe from thunder-bolts? *Pliny* tels us that the Bay-tree, the Sea-Calf, and an Eagle are Thunder-proofe and cannot be smit by a Thunder-bolt. *B.* 2. *Ch.* 55. Some add the Hyacinth Stone, and other coral. Yet most men Count these things but Fabulous, and late authors observe that the Laurel or Bay hath been Thunder Smitten: and *Scaliger* in *Exercit.* 113. disputes against the assertion of *Cardan* touching the Hyacinth. The *motion of a thunder-bolts.* motion of Thunder-bolts is commonly aslope or slanting: because the Fire of its own Nature rends upwards, and the force whereby it is cast out of the cloud drives it downwards. And hence a cause may be rendred, why Thunder-bolts do frequently smite high Mountains, Towers, Temples, Tall-Trees: because seeing Thunder-bolts are commonly moved aslant, the highest things are most Obvious to them, and are therefore more often hurt by them.

At what time of year thunder bolts are most frequent? In Winter and Summer Thunderbolts are rare; in the Spring and Autumn more frequent, as *Pliny* tels us, *Lib.* 2. *Nat. Hist. Cap.* 50. Yet later writers say they are most frequent in Summer, and seldom in the Spring and Autumn; and to their Opinion experience gives witness in our parts; for the hotter the weather, the more Lightnings, Thunders and Thunder-bolts we have. For in great Heats very many hot Exhalations are raised aloft, fit to ingender Thunder-bolts, and through the cold of the middle Region of the Air they are shut up in Clouds, and out of them violently driven down.

The difference of thunder-bolts. As to the difference of Thunder-bolts, *Pliny* divides them (in 2. *Book Ch.* 43.) into Predicting and Brute, perswaded rather by Heathenish Superstition then any Natural Reason. That is a more convenient division of Thunder-bolts, which *Seneca* brings in his 2. *B. of Natural Questions, Ch.* 40. The kinds of Thunder-bolts (saies he) are the Borer, the dissipater, the Burner. That which bores is subtile and flamy, flies through the straitest passages, by reason of the sincere thinness and pureness of the flame. That which dissipates is conglobated, and hath mixt with it the force of a fiery and stormy spirit. And therefore that kind of Thunder-bolt returns and escapes through that hole where it entred in. The force of this Thunder-bolt being spred far abroad breaks what it smites, but doth not pierce through it. The third kind, which burns, hath much Earthiness in it, and is more

fiery

fiery then flaming. And therefore it leaves great marks of burning which abide in the things smitten. Indeed, No Thunder-bolt comes without Fire, but we call this properly fiery, which imprints manifest signs of burning. That which burns and makes brown, doth burn three manner of waies: for either it blasts only and hurts slightly, or it burns, or it kindles.

Strange Colors in the Skie, and Gapings.

To the Meteors whose Nature and Generation hath been Hitherto explained, may not unconveniently be adjoyned the *Phasmata* so called, such as are, wide gapings in the Skies, Ditches, Bloody redness and other Colors in the Skies appearing. For these appear various by reason of the light of Stars or Meteors received in a thick Air, or Exhalations, differing in plenty, Density, and Position. For as a flame appears in sundry Colors, by reason of the various permistion of Fire and Smoak: even so the light of the Stars or Exhalations enflamed, according to the divers dispositions of the matter wherein it is received, doth present to our Eyes sundry Colors and Shapes. For when that which receives the light is very compact and dark, there appears somwhat that is obscure and darkish; if it be not so compact, there is an appearance of a Sky Color; if yet less compact, it appears purple Color'd. And therefore they say a Gaping in the Sky is caused two manner of waies. First, When the light of the Moon, or another Star, or of some Exhalation enflamed (which is I conceive the more frequent cause) falls into a Cloud beneath it, which is compact in the middle, and spungy in the sides. For so the thicker part in the middle, which the Light cannot pierce into, expresses a certain deepness remote from us a great way: but in the outmost parts through which the light passes, it seems nearer to us. For every thing that is black, dark and obscure, although it be as near as that which is white, yet it seems further off then it: for white things do more work upon the sight. And therefore painters also being to express a thing depressed and remote, do use a black Color or that which is near to black; but to express a thing raised and eminent, they use white. After the same manner also Ditches are made. For in them there is only more depth, then in the foresaid Gapings. Of other Colors and Figures appearing in the Air, the Cause is the same. For according to the various disposition of Clouds in their several parts, in respect of thickness and thinness, the shapes of divers Animals are represented, of Mountains, &c. They say that a Gaping is made after a second manner, when a thin exhalation burns above some Cloud, and attenuates the said Cloud in the middle, more and more, so that it seems to be divided into two parts. Which being done, the Exhalation it self appears all on Fire, and the Heaven being as it were opened, seems to burn. Yet probable it is that somtimes such Prodigious Apparitions are by almighty God placed in the Sky, to Denounce some Impendent Calamity, and Experience teaches as much.

A Gaping.

Ditches & other figures and colors appearing.

Chap. 3. *Of the Winds.*

After the Fiery Meteors, we are to treat of Winds and Earth-Quakes. Now although of old sundry Men have had several opinions concerning the Nature of the Winds; and that Opinion chiefly was most Famous and common, which holds that Wind is the Agitation of the Air, or as *Seneca* defines it, *Quest. Nat. Lib.* 5. *Cap.* 1. Flowing or agitated Air: yet that these and other Opinions are of no validity, *Aristotle* shews in *B.* 2. *Meteorol. Ch.* 4. But *Aristotle* himself held thus concerning the Generation of the Winds; that all the Water which falls down in showers, is totally distributed into the Earth, and the Earth hath in it self much heat and Fire; and the Sun doth not only draw that moisture which lies in the upper parts of the Earth, but also by its heating Faculty dries the Earth it self; which Humor being drawn aloft in vapors, is driven back by the coldness of the middle Region of the Air, and agitated and moved athwart.

Wind is not the Air agitated.

The manner of the Generation of Winds according to Aristotle.

For the Matter of Winds, according to the *Aristotelians*, is an Exhalation hot and dry: of which thing they produce these signes. For in the first place Winds do very much dry. (Again as *Cardan* saies in his 16. *de Subtil. p.* 792. (and experience confirmes the same,) red Clouds scattered all over the Sky, or a red Moon, or the Suns setting amongst red Clouds, signifies Winds to follow; only because they

The Matter of Wind

argue

argue that many Hot and Dry Exhalations are Elevated into the Sky. Howbeit the matter of Winds is seldom a pure Exhalation; and some winds are drier then other some, because two sorts of Exhalations, as was said before, are commonly drawn joyntly out of the Earth; and again, because they are mixed with Exhalations and Vapors, through which they pass: and therefore also the Qualities of several Winds are different, as shal afterwards appear, by reason of the vapors they bring with them out of the places through which they blow.

The Efficient cause. Now what should be the Cause of the Motion and Agitation of Winds, authors differ, as may be seen in *Francisc. Piccolhomineus, Lib. de Meteor. Ch.* 22. *Collegium Conimbric. de Meteoris, Tract.* 6. *C.* 3. And verily here is no smal difficulty and obscurity. But most Men hold, that dry Exhalations being carried up to the middle Region of the Air, or thereabouts, are by the coldness thereof driven back; and because by their own Nature they are light and endeavor to mount upwards (but by the violence of the cold Air they are driven down again,) therefore they are forced to move Athwart or Cross the Air. For just as Smoak ascending out of a Chimney, if it meet with Wind is beaten down, and passes obliquely this way and that way al abroad: so they think it no absurdity to say, that an hot Exhalation meeting with the coldness of the middle Region of the Air, is driven back thereby.

Aristotles opinion examined. Now as we do not wholly reject this opinion, since experience it self doth witness, that after Rains Winds are raised in the neighbouring places, vapors being raised out of the Earth moistened with showers; yet some things are to be added and observed concerning the same. For first, though that same violent motion of Winds be chiefly to be attributed to Exhalations: yet the Air it self doth encrease that motion, which being moved by the Exhalations is it self agitated, and forcibly carried this way and that way. Even as when it is moved by ones Hand, by a Whip, or Fann, we perceive it makes somwhat which resembles Wind.

Moreover, although Winds are hardly bred without an Hot and Dry Exhalation, since rarely one kind of exhalation ascends without another: yet nothing hinders but that Cold and moist Vapors may be the matter of Winds; and experience teaches us that there are many cold Winds, and many Winds moist.

Thirdly, 'Tis indeed credible, that out of the Earth moistened with showers many Exhalations do ascend; but Credible it is not, that all the matter of Winds arises from the surface of the Earth, and that the Earth within the compass of ten Foot deep, more or less, can send forth such store of Vapors as will serve to make Winds, which oftentimes out of the same Quarters do most vehemently blow, divers daies together; especially when the Earth continues moist even when the Winds do blow: but without all question the greatest part of Winds do break out of the hollow Caverns of the Earth. For in the Winter Season, when all the Surface of the Earth is hardned with Frost and Cold, yet nevertheless more and more vehement Winds are then raised, then in the Summer time; and Winds arise out of Rivers and Lakes, yea and Storms arise out of the Sea it self. And although some think it improbable, that Winds are raised out of the bottom of the Water, by the working of the Fire which is in the Bowels of the Earth, yet Mariners have oftentimes found it so to be, to their great danger and dammage. For this is that *Æolia* (which *Virgil* describes in his 1. Book of the Travels of *Æneas*,) out of which, as he saies,

> *Huf-puf Winds make all to an Head, and where the Gate's open,*
> *Out they Rush, with a blustring blast, and Blow the Land over.*

Fourthly, Although I will not now dispute this point, whether Vapors and Exhalations raised aloft, are driven back by the coldness of the middle Region: yet nevertheless certain it is, that they when they break out of the Caverns of the Earth, they are not destitute of all force and motion; and that not only an Air arises out of Pools, Floods and lakes, but even out of the Calm Sea oftentimes storms of Wind do arise. Now the Winds in the mean while do receive this force at that time, either from the multitude of Waters which break into the bowels of the Earth, and thrust forth the Air and Vapors there shut up; or from the Fire contained in the

the Caverns of the Earth, and resolving the Waters and other subject matter into Vapors: to which may be added some Huge Fragment of Earth falling down into some vast Cavern of the Earth, and thereout violently expelling the Air. Howbeit, amongst these Causes, the chief seems to be the under-ground heat; and many things argue that it is no less effectual to raise Winds, then the Heat of the Sun. For, as hath been lately said, they break out of Rivers, Lakes, and the Sea also in the Winter time, when the surface of the Earth is hard with Frost. And that same instrument which Chymists use instead of bellows to blow their Fire, doth not a little declare this business. They have a round hollow Globe of Copper, which being filled with Water and close stopped, there is a smal hole on one side or a Pipe with a smal passage: and the said Globe being filled with Water is laid on a Chafing-Dish of Coals, and the foresaid Pipe is instead of bellows turned towards the Fire which they would blow: when the Globe grows Hot and the Water begins to rarifie, there is a perpetual Wind blowing forth, which blows the foresaid Fire like a bellows, til all the Water in the Globe be consumed. To all which causes nevertheless one seems fit to be added, *viz.* The contrariety of those smal particles, whereof the Exhalations which are the matter of Winds do consist. For these particles (as appears by many Chymical operations, wherein for the same cause the Vessels are violently broken, while they abhor and fly one from ther) do raise such a violent motion.

Howbeit, The motion and posture likewise of the Stars, and especially of the Planets, doth also contribute to the Generation of exhalations; which being in this or that part of Heaven constituted, or in conjunction with others, or having mutual aspects; they move somtimes this matter, somtimes that, somtimes in one place, somtimes in another, and variously drive and force the same.

The number of winds vulgarly observed.

The number of the Winds is by various Authors variously reckoned, as may be seen in *Aristotle*, in his 2. *of Meteors*, *Ch.* 6. in the Author of the *Book de Mundo* dedicated to *Alexander* Ch. 4. *Seneca* in his *Quest. Nat.* L. 1. C. 16. *Pliny* in *Hist. Nat. Lib.* 2. *Cap* 47. Gellius, *Book* 2. *Ch.* 22. Who also differ somwhat in the Names and Situations of the Winds. Thus we shal Muster them. All grant that those are the four Cardinal or Principal Winds, which blow from the four Principal points of the Horizon, or the four corners of the World. For from the Equinoctial Sun-rise blows the East-Wind; from the Noone-sted blows the South Wind; From the Equinoctial Sun-set, the West-Wind; and from the Pole Arctick blows the North-wind. The Ancients contented themselves with the notice of these four Winds: the Age following added four more. For, because the Sun doth not alwaies rise and set in the same place, but the Equinoctial Sun-Rise and Sun-set from whence the East and West winds blow, are different from the Solstitial Sun-Rise and Sun-set; and the Winter Sun-Rise and Sun-Set is also different from them: they therfore added yet four Winds more, blowing from the four points of the Intersection of the Tropicks and Horizon, or from the points of the Summer Sun-Rise and Sun-Set, and the Winter Sun-Rise and Sun-Set. For that which blows from the Summer Sun-Rise, they called *Cæcias*; That from the Winter Sun-Rise *Vulturnus*; that which blows from the Summer Sun-Set, *Corus*; that from the Winter Sun-Set, *Africus*. To these Posterity added yet other four, which blow from the Poles of the Zodiack, and their opposite points; or from the sides of the Poles and the Polar Circles, or from the points marked by them in the Horizon; so that every Cardinal Wind came to have two collateral or side winds. And they called that betwixt the North and the Summer Sun-Rise *Thrascias*; and that betwixt the South and Winter Sun-Set, *Libonotus*; that betwixt the South and Winter Sun-Rise, *Phœnicias*. And this is the most usual number of Winds among Authors.

The number of the winds encreased by late Navigators.

Later Navigators have amplified the number of the Winds to thirty two. For they divide the Horizon into eight parts, to which they attribute eight Winds; which they call principal, *viz.* those which blow from the four cardinal points of the Horizon, or corners of the World, and such as blow from the points exactly in the middle of those. To these they add eight others, holding the middle places betwixt the principal, and call them the middle or half Winds: to these they add sixteen more, which they insert in the middle space betwixt the principal and the middle, and cal them Intermediate or Quarter Winds.

I shall here recount the chief of them, which follow one another in this order, from East to South; from South to West; from West to North, and so from North to East again. From the Equinoctial Sun-Rise blows *Subsolanus*, the *East-Wind*; from the middle point betwixt the East and the South, blows *Euronotus*, the *South-East-Wind*; from the South blows *Auster*, the *South-Wind*; in the middest betwixt the South and West is *Notozephyrus*, the *South-West Wind*. From the Equinoctial Sun-Set blowes *Zephyrus*, *Favonius*, the *West Wind*: betwixt the West and North blows *Thrasciozephyrus*, the *North-West Wind*; from the North, the *North Wind*; and betwixt the North and East, the *North-East Wind*.

To these if we shall add eight and insert them in the middle among the principal, (which were also used by the Ancients, and blow from the Summer and Winter Sun-Rise and Sun-Set, and which the sailers call middlewinds or half Winds,) we shal then have sixteen Winds worthy of observation. For betwixt the East and the South-East there is *Vulturnus*, or the East-South-East Wind; betwixt the South-East and the South there is *Phœnicias*, or the South-South-East Wind; betwixt the South and the South-West there is the *Libonotus*, the South-South West wind; betwixt the South-West and the West there is *Africus*, the West-South-West wind; betwixt the West and the North-West is the *Caurus*, *Corus*, or West-North-West wind; betwixt the North-West and the North blows the *Circius* or North-North-West wind; betwixt the North and the North-East blows *Boreas*, *Aquilo*, or the North-North-East wind; betwixt the North East and the East blows the *Cæcias*, or the East-North-East wind.

Contrary winds. The chief thing observeable in these Winds is the contrariety. Now those Winds are most contrary one to another which are most distant one from another in place. Now those are most distant in place which are Diametrically opposite one to another, or by a Line drawn through the Centre of the Horizon. Hence the East is opposed to the West, the South to the North; the Winter Sun-Rise to the Summer Sun-Set, the Winters Sun-Set to the Summers Sun-Rise: and therefore the Winds also which blow from these parts are opposite one to another. So the East-South-East wind is opposite to the West-North-West; the South-East wind to the North-West; the South-South-East, to the North-North-West; South-South-West to the North-North-East; the North-East to the South-West; the East-North-East wind is opposite to the West-South West wind.

The winds blow in a certaine Method. And here it is to be observed, that these winds observe a Rule in blowing. Those which are contrary, because they are Diametrically opposite, cannot blow at one and the same time, but the stronger of the two suppresses the force of its opposite: or if it happen that they blow together, it is with mighty contention and causes an hideous storme. Now, this order the winds do commonly observe, that when one fals that which is next it doth rise; or the contrary to that which ceases doth begin to blow. Moreover in contrary Lines contrary Winds do for the most part blow: concerning which see *Aristotle*, *Lib. Meteor.* 2. *C.* 6. Pliny *in his Natural History*, *Book* 2. *Ch.* 47.

The temper and Qualities of the winds. Again, Here is to be noted the Temperament and Quality of the Winds. For though they al agree in matter, and consist of an hot and dry Exhalation: yet since that is seldom raised up alone, (but that for the most part out of the Sea and the Earth watered with Rains and Snows these two Exhalations are drawn together, & afford matter to the Winds;) moreover that they pass through places Hot, Cold, Dry; therfore there is also a great difference of Winds in respect of the places from whence they arise and through which they blow. For the Winds have not only the Qualities of those places from whence they arise, but their chief qualities they have from the places through which they pass.

Hippocrates in his *Book de Aere, Aqua, & Locis*, divides al the Winds into Hot and Cold, because the force of these qualities is greatest: whom *Aristotle* following in his 2. *Meteor. Cap.* 6. divides all Winds into North and South Winds, even in respect of Heat and Cold also. To the Northern he adds the Western Winds, and to the Southern the Eastern. The North-Winds are the coldest of all other and Dry, for they arise from Snowy cold places, and pass through places out of the Suns way and far from the Heat thereof. With these agree the West Winds. For these are cold Winds, because they pass through places not much heated by the Sun. To the North-Wind the South-wind is opposed, an hot wind, which passes through

through the Suns road, and through places heated by the Sun: in *Libya* indeed it is dry, becauſe the moiſt vapors are there conſumed by the Sun: but to us it is moiſt, becauſe it comes over the Mediterranean or Mid-land Sea. The Eaſtern Winds are Hot and dry. For the Sun is carried long over thoſe places through which they come.

The Eaſt-wind is Hot, Dry, temperate, Sweet, Pure, Subtile, Healthy, eſpecially in the morning: and therefore it brings no Venemous blaſts. The Eaſt-South-Eaſt becauſe nearer the South is moiſt and cloudy, and therefore when it blows all things do ſeem to be bigger then indeed they are, as *Ariſtotle* hath it in the 26. *Section* of his *Problems*, *Problem* 56. The Eaſt-North-Eaſt, is inconſtant and ſomwhat cool. It drives not the Clouds away, but draws them to it ſelf; whence the Proverb: he draws evils to himſelf as the Eaſt Nor-Eaſt Wind draws the Clouds. The Weſt wind melts the Winter Snow and Froſts, being of an Hot and moiſt temper, making the Herbs and flowers to grow; and therefore 'tis thought to have its Name in the Greek *Zephuros*, as if you would ſay *Zoen Pheron* bringing Life.

The Weſt-South-Weſt, is Cold, Moiſt, Rainy, tempeſtuous. Hence *Virgil* calls it *Creber Procellis*, in the firſt of his *Æneids*, ful of Storms. The Weſt-Nor-Weſt, is Stormy, Snowy, Hailing, Cold. Therefore *it*, and the North-wind, are the coldeſt winds of all.

The South-wind is moiſt, Hot, Thundering, Peſtilent, engendring Clouds and Store of Rain, making the Air thick and Cloudy.

The South-South-Weſt is a temperate wind, Hot, Rainy, and ſomtimes Thundering.

The South-South-Eaſt wind is Hot and Moiſt.

Wherefore the South-wind, the South-weſt wind, Weſt-South-weſt winds are hot, but of theſe the South-wind is Hotteſt, Hurtful and Peſtilent.

The South-South weſt is more moiſt then Hot. Howbeit, conſideration muſt be had of the Climate and the place.

The North-Nor-Eaſt wind is Cold and Dry, the Author of Cold, cutting the Clouds, ſtraitning our Bodies and ſhutting their Pores: making the Humors more pure, and Purging the peſtilential Air.

The North-Nor-weſt is the Author of Snow and Hail.

The North-wind is Cold and dry, without Rain, hurting Flowers, Fruits and budding Vines. And therefore the North-Nor-Eaſt, North and North-Nor-weſt winds do Purge the Air; and if they be not vehement cold, they make it clear and fair weather; but eſpecially the North-Nor-Eaſt and the North winds; and the North-Nor-Eaſt brings Hail, and the North-wind brings Snow. And Generally all winds from the North and Weſt are drier then from the South and Eaſt.

Hence ſome winds are healthy, others unhealthy. But in general the Southern winds are of all other moſt unwholeſome. For they cauſe moiſture and putrefaction: and therefore when it blows, neither Cellars, nor Houſes, nor Libraries, nor Granaries ſhould be ſet open. The South-wind is more violent in the Night, the North-wind in the Day: the South-wind on the Sea, and the North-wind on the Land. *Of winds ſome are healthy, others unhealthy.*

A ſhort and moderate South-wind makes the Air clear; but a great and laſting South-wind Clouds the Air, and is wont to be more furious at the End then at the beginning: and therefore it brings more Rain at the Concluſion, then at firſt: but the North-Nor-Eaſt wind doth the contrary.

Thoſe winds which come through Populous places, as Cities ful of people, and where a great Army hath been long incamped, through Stinking and Venemous places, are hurtful: but thoſe which come through healthy places, as pleaſant Meddows, woods, and along running waters, are wholſome, for they are Seaſoned with the Steams of Flowers, Leaves and Herbs. More obſervations concerning the force of winds are to be read every where in the writings of Phyſitians, and in *Pliny* in the place fore alledged; alſo ſome things may be brought out of *Ariſtotle* touching this ſubject, *Probl. Sect.* 26.

And theſe are the common winds which blow every where all the world over. There are alſo other winds peculiar to ſome places. The former are termed com- *Provincial winds.*

mon to all places, not becauſe ſo many blow in all places; for there are ſome Regions where thoſe common winds cannot come, by reaſon of High-Mountains and other Cauſes: but becauſe, no where there are found any more. And the latter are termed Provincial winds, becauſe they go not beyond a certain tract of ground and abide in the place where they were ingendred not being able to blow further: becauſe they are bred of a ſmal Quantity of matter, which failing, they alſo do fade away. And ſuch are commonly thoſe winds which are called *Subterranean*, which come out of Caverns of the Earth, and from Exhalations bred in thoſe Cavities which are neareſt the Surface of the Earth. Or becauſe they are particles of the common winds, ſeparated from them by the height of Mountains, deepneſs of Valleys, or the Heat or Cold of the Place. Of which ſee *Seneca*, *Queſt. Nat. B.* 5. *Ch.* 19. *Pliny* in his Natural Hiſtory *Lib.* 2. *Ch.* 47. Gellius *Book* 2. *Ch.* 22.

Anniverſary winds There are alſo univerſary winds, which return every year at ſet times, and they are chiefly three: The *Onithiai* or Bird-winds, the *Prodromoi* or forerunners, the *Bird wind.* *Eteſiai* or Anniverſary winds Particularly ſo called. The Bird-winds called alſo the Roſe-winds, are a ſort of Weſterly winds, which blow gently every year in the Spring Seaſon, when the Swallows and other Birds returne to our Parts, and *Fore runners.* when Roſes flouriſh. The *Prodromoi* or Forerunners, are Northern winds which come eight daies before the riſing of the Dog-Star, ſo called becauſe they proceed *Eteſian winds.* the *Eteſian* winds. The *Eteſian* winds are ſo called from *Etos Annus*, as if you ſhould ſay Anniverſary winds Particularly ſo called, becauſe they keep their courſe moſt certainly every year, two daies after the Riſe of the Dog ſtar, and blow forty daies together; now they are Northern winds, pleaſing and healthful to man and beaſt. For by their blaſt they moderate the Heat, break the violence of the Summer, and defend us from the violence of the hotteſt months. They riſe at the third hour of the day, and therefore they are called ſleepy winds and Dainty Nice winds by the Mariners, as *Seneca* tells us, *Nat. Queſt. Lib.* 5. *Ch.* 11. and at night commonly they leave blowing. Authors conceive thoſe winds are bred by great heat, melting the Snows yet remaining on the Northern Mountains. For 'tis likely, that the Lands diſburthened of the Snow and uncovered do breath out more freely. And therefore they do not laſt beyond the Dog-daies; becauſe after them all places are bared, or at leaſt very few do continue covered with Snow.

Turbulent winds. The winds do ſomtimes raiſe great Tempeſts, and are exceeding turbulent; the chief whereof are *Ecnephias*, *Typhon*, and *Preſter*. The generation of the wind *Ec-* *Ecnephias* *nephias* is thus deſcribed by *Seneca* in his *Lib.* 5. *Queſt. Nat. Cap.* 12. when a great inequality and diſſimilitude of Bodies, ſent out by the Earths vapor, doth aſcend aloft, and ſome of theſe Bodies are dry, others moiſt, from ſo great a diſcord of Bodies fighting together, when they are gathered into a Globous Body, 'tis like that ſome Clouds are made hollow, and that *Fiſtulous* ſpaces are left in them. in manner of hollow ſtrait Pipes. In theſe ſpaces a thin ſpirit is intercepted, which deſires a greater ſpace, when being ſmitten and cuft together in its narrow paſſage it grows hot, and ſo becomes wider, and cuts aſunder its incloſures, and breaks out into a Wind, which is really ſtormy, coming down from aloft and falling vehemently and fiercely upon us, and making it ſelf way by force and fighting. This wind is called by the Greeks *Ecnephias*, becauſe it comes ruſhing *Ec ton Nephon*, out of the Clouds.

The whirl-wind But if the ſaid Exhalation be divided into parts, and breaks either out of divers Clouds, or out of divers parts of the ſame Cloud, it cauſes a Whirl-wind. For, becauſe the wind ſeeking Egreſs meets another, and is forced as it were out of a wide into a narrow place, it is alwaies driven to one ſide where it may find a paſſage, and makes a wheeling motion; by and by being conglobated and mixed with ſome part of the Cloud, it is carried Head-long, and being repulſed and beaten back by the Earth carries what ever it meets with its whirling motion, aloft into the Air; it is the chief Plague of Mariners, as *Pliny* ſaies in *Lib.* 2. *Nat. Hiſt. Cap.* 48. bowing and breaking, not only their maſts but the very Ships themſelves.

Preſter, But if the ſaid Exhalation be of an hotter Nature, and by *Antiperiſtaſis* or Motion be ſet on Fire, and carry the Flame along with it, 'tis called *Preſter* from burning. *Seneca* calls it the Fiery whirl-wind, *Queſt. Nat. Lib.* 5. *C.* 13. This doth not only overthrow, but burn al that doth ſtand in its way: and herein only it differs from a Thunder-

a Thunder-bolt, in that it hath more Wind, and leſs Flame; but in a Thunderbolt there is more Flame and leſs wind. *And ſo much for Winds.*

Chap. 4. *Of the Earth-Quake.*

Ariſtotle relates the differing opinion of Authors touching the Earth-Quake, (which the Greeks term *Seiſmos*,) in his 1 *B. of Meteors Cap.* 7. Seneca *Lib.* 6. *Queſt. Nat. from Chap.* 5. to 21. Plutarch *in his* 3. *de Placit. Philoſoph. c.* 15. Pliny *B.* 2. *Nat. Hiſt. c.* 79. Gellius *B.* 2. *ch.* 28. from whence we may ſee how careful the Ancients were in ſearching out the Cauſe, why that which is the only immoveable and fixed thing in the world, which ſubſtains us and all things on it ſelf, upon which Cities are built, which ſome have called the foundation of the World, doth ſomtimes reel and ſtumble. We, deſirous to obſerve Brevity, omitting the examination of other Opinions, ſhall only lay open the Truth.

Seeing the Earth is of it ſelf immoveable, nor can be moved by any thing which Externally goes about the ſame, as winds or waters, (againſt the Motions and moſt Vehement Tempeſts whereof the Earth hath formerly ſtood and doth ſtill ſtand immoveable:) 'tis to be thought, that it is moved in Earth-quakes from ſomwhat within it ſelf. Now in the Caverns of the Earth are included Waters and two kinds of Exhalations. Now although that *Gellius* tels us, *Lib.* 2. *Cap.* 8. that the moſt Ancient Greeks were of Opinion, that the Earth was moved by the Floods and Violent Motions of Waters abounding in the Caverns of the Earth; (and therefore they call *Neptune* the Earth-ſhaker:) yet waters being not very apt to move, nor diſpoſed to moſt ſwift and violent Motions cannot be accounted the Cauſe of Earth-quakes. Which is alſo confirmed by what *Scaliger* relates in his 38 *Exercitation.* There is ſaies he in the Weſterne part of the Iſland of *Hiſpaniola* a Mountain of huge Height, which hath many hollow Caves within it, whereinto Rivers are tumbled down with ſo great a noiſe and roaring of the waters that they are heard five Miles of, yet no Earth-quake is cauſed thereby. And the like Judgment we are to make of moiſt Vapors.

Waters are not the Cauſe of Earth-quakes.

The Cauſe therefore of an Earth-quake muſt needs be hot and drie Exhalations. For hot and dry Spirits are fitting to raiſe Motions moſt ſwift, Violent and Vehement, which is alſo apparent from Thunder, Thunder-bolts, Winds, Whirle-winds, Storms, and Guns: and every hot thing doth of its own Nature tend upwards. Alſo there are other Tokens hereof. For Hiſtories bear witneſs, that for the moſt part, after an Earth-quakes a great abundance of winds and ſpirits have broken forth, and have caſt Stones, Aſhes, and other Obvious things out of the Caverns of the Earth; yea and the moſt Earth-quakes have not ceaſed till thoſe winds included have made an Eruption: which *Ariſtotle* tels us did happen about *Heraclea* of *Pontus*, and the Iſland *Hiera*, *in the* 2 *of his Meteors*, *Chap.* 8. Moreover, moſt Earth-quakes happen, when the Sea is Calme and the Air free from winds; *viz.* When all the matter of Winds is contained in the Caverns of the Earth. You may finde more ſigns in *Ariſtotle*, in the Place foreal-ledged.

The true Cauſe.

Now ſome hold, that theſe Spirits are either bred in the Caverns of the Earth by the Heat of the Sun and of the underground Fire; or that being bred without, they enter in; or that they are driven thither by the *Antiperiſtaſis* of the cold Air; or that when two contrary Winds do blow at once, the one being vanquiſhed by the other doth paſs into the Caverns of the Earth which it meets with; or to avoid Vacuity, when the waters go out, the Exhalations inſinuate themſelves into the hollow parts of the Earth. But the firſt amongſt theſe Cauſes is either the chief or only Cauſe. Now the Spirits which ſhake the Earth are contained in the profound Caverns thereof. For thoſe which are in the Cavities next the Surface of the Earth, ſeeing they can eaſily finde an Egreſs, do not move the Earth. Now theſe Blaſts are moved, becauſe they have no place in the Caverns of the Earth fit and large enough, or becauſe they are preſſed by the Waters which flow to and from the Sea; or becauſe they are ſhut up by the *Antiperiſtaſis* of cold, and gathering force, and their heat being Augmented, they are Attenuated and Rarified; which alſo may be performed by the *Subterranean* or Under-ground Fires.

Proſi

From the Premiſes therefore it appears, that an Earth-quake is cauſed, when hot and drie ſpirits are Præternaturally ſhut up in the Caverns of the Earth, and ſeek their way out. For, not finding the ſame they move this way and that way, and by their great force and violence they ſhake the Earth. Now the ſundry manners and various faſhions of Earth-quakes proceed from the greater or leſs Quantity of Exhalations; from the divers figures of the Caverns; from the longneſs or ſhortneſs of their diſtance from the Earth; from the ſundry manners of the Exhalations breaking forth; which the Author of the Book *de Mundo Cap.* 4. and others do reckon up. Yet all of them may be referred to two, whereof one may be called *Tremor* a trembling; which is cauſed, when much Spirit is ſpread out Long-waies and Broad-waies: the other *Pulſus* a beating or thruſting, when the Exhalation is diſpoſed rather long-waies. For it ſeeking Egreſs lifts up the Earth much after the ſame manner as the Arterie is lift up in the Diaſtole or widening of the pulſe.

Two manners of motion of the Earth.

From what hath been hitherto ſaid, it appears, that the whole Earth cannot be ſhaken at once. For the Spirits ſhut up in the Caverns of the Earth have no proportion (to ſpeak of) to the whole Globe thereof, nor have ſo much ſtrength in them. And therefore, if there be any univerſall motions of the Earth, they ought to be referred rather to the infinite power of God, then to Natural Cauſes. With the Earth-quake is ioyned a noiſe, cauſed by the vehement Motion of the Spirits running to and fro in the Caverns of the Earth, and ſmiting againſt the ſides of the Earth; which noiſe ſomtimes goes before the Earth-quake, and is a ſign thereof ſuddenly to follow; ſomtimes it accompanies the ſame, and it is various, according to the Quality of the matter receiving, and the form of the *Cavities*, or paſſages through which it goes.

Univerſal Earth-quakes are not natural.

The duration of an Earth-quake is not one and the ſame alwaies, but divers, according as the Earth doth more or leſs reſiſt, or gives an eaſie or difficult paſſage to the winds; or as the Spirits themſelves are plentiful or ſcanty. For few Spirits are ſooner diſcuſſed and ſooner get away, but ſtore of Spirits abide longer; alſo when there is a wide paſſage for them to go out, they go out apace; but when the paſſage is ſhut up or is very narrow, they get out more ſlowly and continue their Buſtling longer. So *Seneca* in *Nat. Queſt. Lib.* 6. *Cap.* 30. Relates that *Campania trembled continually for divers daies together.* And *Livy* in *Decad.* 4. *Lib.* 4. Writes thus: In the beginning of the year, when *L. Cornelius*, and *Q. Minutius* were Conſuls, there were ſo many reports of Earth-quakes, that Men were weary not only of the thing it ſelf, but of the many Solemn daies appointed becauſe of the ſaid Earth-quakes. And the ſame Author in his 4 *Decad. Lib.* 5. tels us, there was an Earth-quake for forty daies together; yea and *Ariſtotle in Lib.* 2. *Meteor: Cap.* 8. and *Pliny* in the 2. *of Nat. Hiſt. Chap.* 8. tels us that Earth-quakes have ſomtimes laſted a year or two years together, and that they have returned at certain Times and Seaſons.

How long the Earth-quake laſts.

The Effects truly of Earth-quakes are wonderfull and horrible. For many times, (as *Seneca in* Lib. 6. *Nat. Quæſt. Cap.* 1. Speaks,) *it doth not only ſwallow up ſingle Houſes, Families or Cities, but it overthrows whole Nations and Regions, and ſomtimes overwhelms them with Ruins, other-whiles covers them in a deep Gulf, not ſo much as leaving any appearance of them: ſo that the Earth is ſpread over moſt Noble Cities, not leaving any marke of their former Exiſtence*: which happens when by impulſe of the Spirit the Caverns of the Earth are ſhaken and fall in. And ſomtimes indeed, the Cities and Houſes are not ſwallowed up in the *Cavities* of the Earth, but the Earth raiſed up in a tumor, they fal down flat. Hiſtories are full of ſuch calamitous accidents. In the Reign of *Tiberius Cæſar* 12. Cities of *Aſia* were in one Night overthrown with an Earth-quake, as *Pliny* relates in the 2. *B. of his Nat. Hiſt. Cap.* 84. He alſo relates that in Crete a Mountaine was broken by an Earth-quake, *Book.* 7. *Cap.* 16. *Theodoretus* tells us *in the* 2. *Book of his Eccleſiaſt. Hiſt. ch.* 25. how the greateſt part of *Nicæa* was overthrown. Of the overwhelming of *Helice* and *Buri* *Seneca* writes in *Hiſt. Nat Book* 6. *Ch.* 23. 26. 32. And *Ovid in the* 15. *B. of his Metamorphoſis.*

The wonderful effects of Earth-Quakes.

Many times alſo in the Sea a Gulf hath been opened, and the waters ſwallowed up, as Rivers on the Land, ſo that the Fiſhes and Ships have ſtood on dry ground. Contrarywiſe, many times the Earth ſwelling on high hath not ſetled again, producing Mountains on the maine Land, and Iſlands in the Sea: whereupon alſo ſomtimes the Sea hath been

been raised aloft like a Mountaine, and hath afterwards fell in upon the Neighbouring Lands. Such an Earth-quake *Socrates* speaks of *in the* 2. *Book of his Ecclesiastical History, Chap.* 3. For the same Cause the Courses of Rivers have been somtimes changed by Earth-quakes, *viz.* a Tumor or swelling of ground being raised up in the middest of the former Channel. Somtimes new Rivers have broken forth, the ways being opened through which the underground Waters are carryed. Somtimes Fire and Ashes are cast out by an Earth-quake: somtimes a Venemous Spirit is belched forth, which proves baneful to Man and Beast. *Seneca* tells in *B.* 6. *Nat. Quest. ch.* 27. of a Flock containing Six hundred Sheep, all kil'd by an Earth-quake. Many other mischiefs also an Earth-quake brings with it, all which were contained in that one Earth-quake which happened under *Theodosius*, which is described by *Euagrius* in the 1 *B. of his Ecclesiastick Hist. Chap.* 17.

And we may wel believe, that Earth-quakes bring not only present mischiefs, and that the danger is not alwaies in the motion, but that there is as great or greater foretold by Earth-quakes; and *Pliny* saies wel, *Lib.* 2. *Nat. Hist. cap.* 84. that *Rome* was never shaken with an Earth-quake, but it was the sign of some Event to follow. And very many Histories Testifie, that the same hath happened in other places.

And therefore look what the Romans did of old, who when they felt an Earth-quake, or heard tidings thereof, they made Proclamation that the people should keep Solemn daies for that Cause, as *Gellius* tells us, *B.* 2. *chap.* 28. much more should we, when such Calamities are present or impendent, cal upon God by Prayer. For that which the Romans feared, (as the same *Gellius* records, *in the same place,*) viz. lest by naming of one god instead of another, they should engage the People in a false Religion, and therefore they durst not in their Edict, as was the usual manner, Name or appoint to what god the People should sacrifice; that have we no need to fear, to whom that God is known, who being angry, the Earth trembles and the Foundations of the Hils are shaken, 2 *Kings. ch.* 22. ver. 8.

Chap. 5. *Of the Clouds.*

WE have Hitherto explained those Meteors which are bred of an Hot and Dry Exhalation; we come now to those which are bred of a vapor in the middlemost and lowest Regions of the Air. In the middlemost Region are ingendred Clouds, Raine, Snow and Hail.

How a Cloud is ingendred.

A Cloud is engendred when vapors being raised aloft, either by heat which they have received from the Sun, or other heating causes, or by hot Exhalations mixt with them, are assembled in the middle Region of the Air, so that they cannot be penetrated by the sight. For a Cloud is nothing else but a vapor raised up in the middle Region of the Air, and there compacted; which appears hereby, in that in the lower Region of the Air, when vapors and Exhalations are raised out of things which boil or burn, they represent Clouds; and because they that walking beneath see Clouds upon Mountains, when they ascend to the tops of the said Mountains, they walk through the Clouds as through Mists; and because as soon as the said Exhalations are condensed they remain no longer Clouds, but turn into Rain.

What a Cloud is.

The height of the Clouds.

Touching the Height of Clouds, Authors are at variance. Some conceive that the Clouds are not above three miles distant from us; yea and that some of them are not above half a mile high. Others write that no Cloud is above nine miles distant from the Earth. *Vitellio* is of opinion, that the vapors ascend 52000, paces, or 13. German miles. *Cardan* in his *book de Subtil. Lib.* 4. *p.* 205. reprehends *Vitellio*, and avers that the highest which vapors mount is 772000. paces, or 193. German miles. Howbeit, 'tis like enough, that the height of the Clouds is not alwaies the same, but various, according to the variety of the matter, places and times: Yea, and we often see with our Eyes, that at the same time and in the same Region, one Cloud is higher then another, and that one goes above another. I my self have seen two clouds carried with contrary motions: and one moving above the other, towards the East; the other moved under the other, toward the West. Also experience shews that clouds are not so high, as some imagin. For the tops of some Mountains reach above the clouds. For the Mountains *Olympus* and *Athos* are so high that Ashes left upon their tops all the year long have neither been blown away by Winds, nor washed away with Rain. And such as have stood on the top of *Vesuvius* have observed that some clouds were just as high as the Mountaine, and some much

much lower. To which that agrees which *Zabarella* writes in his 8. *Chap. de Regionib. Aeris.* I went saith he, to the top of *Venus Mount*, which is the highest in the Territory of *Padua*, and there I found the Air clear all day long; but beneath, about the middle of the Mountain, I saw the Clouds, which hindred me from seeing the Valleys: and in the Evening being come down from the said Mountain, I found that there had been a great Rain that day, below, whereas it Rained not at all on the Mountains top. *Francisc. Piccolhomineus* de Meteor. C. 11. saies the same, how that Men living upon high Mountains, or Travailing thereupon, do see the Rains below them in the Valleys; whereas they themselves are in clear weather; and he saies the same happened to himself travelling over the Alpes and the Apennine Hills. And any man may observe the same in Mountanous places.

The Colors of Clouds. The Colors of Clouds are various, according to the various disposition of the matter receiving the Beams of the Stars, and especially of the Sun, which *Pontanus* thus describes.

Hexameter verses.

The white Cloud's not very thick, and mixt with a thinspred Vapor,
Through which the Sun with his raies doth break to the inside.
The black Cloud is ful of a thick dark Smoak and a Vapor,
Not at all to be pierced through, by the Beams of the Sun-shine.
In a Purple Cloud's much heat; and Good Store of Humor
In the blew colord Cloud is hid, which lustily Raineth.

Chap. 6. *Concerning Rain.*

SOme Clouds are termed barren, which are white and Transparent, and do rather by agitation of the Winds turn into Air then showers: others fruitful, which being moister then the former, are fit to engender Rain. For Rain is nothing but a Cloud, Cooled, Condensed, and turned to Water. And Rain is bred, when the vapors which make a Cloud are yet more condensed, and turned into Water; which being heavier then the Air fals down of its own accord in drops. For Rain is made after the same manner as hot vapors upon the walls of Baths, or in the Winter in hot stoves, upon Globes of Glass, Iron or Tin jugs that are cold, are turned as we see into Watry drops.

What Rain is and how 'tis bred?

Diversity of Rains. Now there is some diversity of Rains, proceeding from the variety of the Clouds, and of their place, which is somtimes higher and somtimes lower. For when the Cloud is High, Unequal, Spungy and Barren, and few smal drops fal like Dew, they are called *Pscades* heat-drops. But if the Cloud be more near and compact, and the drops fal down thicker, 'tis called *Imber* a shower. Finally, if the Cloud be yet thicker and suddenly condensed by a greater cold, and greater drops fall more thickly, 'tis called *Nimbus* a strong shower. Yea and somtimes whole Clouds are so condensed by a sudden cold, that the waters descend not drop by drop, but come down in streams, and destroy Towns and Cities; and then they say a Lump of a Cloud is fallen down.

Pscudes. *Imber.* *Nimbus.* *The Lump of a Cloud.*

Prodigious Rains. Also there are *Prodigious Showers* so called, such as we read of every where in Histories, *Tit. Livius* relates in *Decad.* 3. *B.* 7. that it Rained Milk, as doth *Pliny* also in *B.* 2. *Nat. Hist. C.* 56. and *Livy* tels us that it Rained Blood, *Decad.* 3. *B.* 4. *Decad.* 4. *B.* 10. and *Pliny* in the place forecited. Also that it Rained Flesh *Livy* tels us in *Decad.* 3. *B.* 3. and *Pliny* in the foresaid place. That it Rained Stones in many places *Livy* relates, *Dec.* 1. *B.* 7. *Dec.* 3. *B.* 1. 234. 6. 9. 10. *Dec.* 4. *B.* 5. 68. *Dec.* 5. *B.* 1, 2, 3. That it Rained Earth the same *Livy* informs us, *Dec.* 4. *B.* 4. 57. *Dec* 5. *B.* 5. *Pliny*, in the *forecited place* writes, that it hath somtimes Rained Iron, Wooll, and Bricks. Authors tel us that Fishes have somtimes fallen down in Showers of Rain: and those Frogs and worms which are seen after Rain are by some thought to have fallen down with the said Rain. Yea and some relate out of *Avicenna* that once on a time a Calf fel out of the Sky.

Their Causes. Most of these Prodigious Rains are to be ascribed to Superior Causes, *viz.* To God warning Men of Evils to come; and to the Devil, indeavoring by such Prodigies to draw men into Errors and Superstitions: yet some of them may also be

referred to Natural Cauſes. True Bood and Milk cannot Naturally deſcend in ſhowers; ſince they are bred only in living Creatures. Yet nothing hinders but ſomwhat like them may fall down, *viz.* When by the Sun-beams a vapor is drawn out of a red or white Earth, or is aloft ſo digeſted, that it may ſhew ſuch a color, and being afterwards reſolved into Rain may reſemble Milk or Blood. And that ſmal Stones may be made by a great heat of ſtore of dry Exhalations in the Air, is a matter ſounding like Truth.

As for thoſe kind of living Creatures which may otherwiſe be bred of Putrefaction, ſuch as Frogs, were muſt hold, that either they are ingendred of ſome matter in the Earth moiſtened with ſhowers (which ſeems to many men moſt probable) or that they lie hid in the chinks and Caverns of the Earth, and by the falling of the Rain are called out as it were and ſo leap forth. But incredible it is that more perfect Animals which are generated only of Seed, and great Stones ſhould be bred in the Air: but likely it is they have been caught up by whirlwinds in one place, and thrown down in another. Now there are certain ſigns of Rain as of other Tempeſts, which would be too long to reckon up in this place, and long Catalogues of the ſame are ſet down by others. But the principal may be ſeen in *Plimes* 8. *Book Nat. Hiſt. C.* 55. And in *Virgils* 1 *Book of Husbandry.*

Chap. 7. *Of Snow and Hail.*

How ſnow is bred?

OF the ſame matter with Rain is Snow alſo made. For Snow is bred of a Vapor raiſed to the middle Region of the Air or ſomwhat lower, or of a thin cloud before it is turned into Water and Rain, congealed by vehement Cold, and torne into parts or flakes, which deſcend like ſoft Wooll, ſomtimes greater, other whiles leſſer, according to the vehemency of the Cold. Now Snow is bred in the Winter time chiefly, becauſe the cold is then ſtrong and vehement, ſo that it is able not only to condenſe vapors into clouds and Rain, but alſo into Ice. For Snow as *Seneca* ſaies, *Queſt. Nat. Lib.* 4. *cap.* 3. is nothing but a kind of Ice bred in the Air.

The color of Snow why white.

Now Snow is white, becauſe 'tis ingendred of a Spungy tranſparent cloud. And that which is tranſparent, after it is terminated, doth next of all become white, becauſe that color is moſt of kin to tranſparency. This appears in Chryſtal or Tranſparent Glaſs, and clear Ice; whoſe ſurface if a man render uneven, ſo that it is no longer tranſparent, or break and grinde it into ſmal parts, in room of tranſparency whiteneſs is produced. It happens ſomtimes, that, when the lower Region of the Air is a little hotter then ordinary, the Snow as it fals down doth melt when it comes there; and ſo, that which is Snow above, is Rain below. And therefore frequently when it Rains in Valleys, it Snows upon the high Mountains. And for the ſame cauſe on the higheſt Mountains, when there is no Snow to be ſeen on the Plain ground, there hath been Snow lying, even in the middle of the Summer. Touching the good which Snow doth to fruits and Trees, read *Pliny* his 2. *chap. of the* 17. *Book of his Natural Hiſtory.*

Hail what it is, and how and where Generated.

Beſides Rain and Snow, of Clouds alſo there is bred Hail. For *Hail* is nothing but congealed Rain; and it is bred, when a Cloud is diſſolved into Rain and deſcends, and in its coming down by extremity of cold 'tis congealed into little round Balls. Now Hail is congealed, not only in the middleſt, but alſo in the loweſt Region of the Air. Which may hence be gathered, becauſe ſomtimes Chaf is found congealed in Hail-ſtones, which Chaf as it was coming down the cold alſo intercepted, and ſhut up in the congealed Water. If the cold be remiſs a certain imperfect and ſoft kind of Hail is bred, of a middle Nature betwixt true Hail and Snow, which they term *Granula*, and reſembles ſmal Sugar-Plums, and this fals chiefly about the End of Winter. Before the falling of Hail, for the moſt part great and terrible ſounds are heard in the Air, which are cauſed by the great conteſt of Heat and Cold in the Clouds. Hairs, and Chaf, and other things which are ſomtimes encloſed in Hail-ſtones, have been carried aloft by the Winds, and congealed together by the Cold.

manytimes there are ſtrange figures in Hail.

And whereas ſomtimes ſtrange Figures are ſaid to be ſeen in Hail, it is partly to be aſcribed to the Fancies of Men, who looking intently upon the Snow, do conceive there

therein Sundry Images, as they do in the Clouds; and partly to the divine Power, which may imprint certain resemblances in the Snow, whereby men may be admonished of some faults in their life and Conversation.

Chap. 8. *Of a Mist, Dew, Hoare Frost,* Honey *and Manna.*

ALso of a Vapor some Meteors are Generated, in the lower Region of the Air, which must also be mustered. And to begin with a Mist, the Author of the Book *de Mundo*, in his fourth Chapter thus describes it: *A Mist is a certain dewy exspiration, not apt to turn to Water, thicker then the Air, more spungy then a cloud. 'Tis bred either of the beginnings of a cloud being rarified, or of the Reliques of a cloud.* In which words he determins that a mist is a certain vapor, thicker then the Air, thinner then a cloud, hovering over the Earth, bred of an Exhalation growing thin, which should otherwise have been the matter of a cloud; or of the thinner parts of a cloud, unfit to ingender Rain, and remaining after it. And therefore a Mist is a token of Fair weather to follow. There is also another Mist, which consists of thicker vapors, exhaling out of the Earth, which also by Reason of their thickness, and the smal heat in them, cannot be carried aloft, but settles in the lowest part of the Air; and so they cause a darkness; and if by the heat of the rising Sun they be discussed and extenuated, they intimate fair weather; but if they be drawn up all together into the Air, being there congealed by the coldness thereof they become matter of Rain.

what a Mist is?

The Dew where and how ingendred.

Now Dew is made of a smal Quantity of a thin vapor, which because of the weakness of the heat reaches no further then the lowest Region of the Air, and indeed below the upper part thereof, and being by the cold of a temperate night turned into smal drops of Water, it sticks to Plants and other things. For the dew is chiefly found on the Leaves and Flowers of Plants, especially where they are smooth and thick; and sometimes also in other parts of them, as also upon Stones. For though it fals alike upon all places below; yet either by reason of their frequent pores, and roughness, or by their heat, it is drunk up and dissipated. On high Mountains there is no Dew bred; and sometimes also it rises not above two cubits, and only the grass is moistned thereby, but things a little higher remain dry. Dew therefore differs from Rain, only in the paucity of the matter, the place where it is bred, and the weaker heat whereby it is congealed. Now Dew is Generated chiefly in the Spring and Fall: but in the Heat of Summer and Cold of Winter it is not bred. For the Heat consumes the matter; and the cold suffers not the Vapors to be raised. Also it is not Generated, but when the Sky is calme and clear; because when the Sky is troubled and agitated with winds the vapor is dispelled, and cannot be congealed into Dew. Likewise Dew never fals but in the morning and Evening. For in the day time it is consumed by the Suns heat, and degenerates into a very thin and light Spirit, so that if an Eg-shell be filled with Dew, and the hole stopped with Wax, or other Glew, and it be then exposed to the Sun, the Eg-shell will mount aloft; the Dew being changed into a most thin vapor and spirit, which ascends upwards, and carries the Eg-shell with it. The Chymists teach, that Dew contains in it the most subtile part of Nitre and Volatile Salt, which is contained in the surface of the Earth, and therefore it is used to make Extracts.

The Nature of dew explaind by the Chymists.

Hore Frost doth not very much differ from Dew; for Hore Frost is bred, when a thin Vapor in a smal Quantity is lift up from the Earth, and cannot rise high, but by the vehement cold of the night it is congealed, before it turns to water. Therefore, look what Snow is in the middle Region of the Aire, that is Hore Frost in the lowest Region; and what is Rain above, is Dew below.

Hore-frost how ingendred.

what honey is, and how it is bred?

Also Honey is to reckoned as a kind of Dew, touching the generation whereof, this is the common Opinion: that with the Vapors which are drawn up in the day time out of Waters and Moist places, for the most part, Hot, Fat, and subtile Exhalations are lifted up, not only out of the Earth and Water, but also out of Plants and other things, which being throughly mixed with Earthy Watery and aery parts, and concocted by the heat of the Sun in the day time, and then by the moderate cold of the Night condensed, they stick upon Plants like Dew. And

that

that Honey is nothing else but a juyce, consisting of Exhalations and vapors, mingled and digested in the Air, by the Heat of the day, and congealed by the nights Cold, and so descending in the manner of Dew.

Which opinion as it is not quite to be rejected: so it seems not satisfactory of it self. For if the Dew be easily elsewhere dissipated and discussed by the morning beams of the Sun: How comes it that Manna and Honey are not also dissipated. Also manna and Honey differ not a little from Dew; nor hath Dew of it self any Fat or Clammy parts. And therefore this also seems fit to be added: that out of Plants a certain juyce and Native Vapor doth distil or breath out, which nevertheless is dissipated by the day-heat of the Sun: but it is at night mingled with the falling Dew, which hinders it from being dissipated, and grows with it into one Nature. From whence 'tis easie to shew a Cause, why there is more Honey gathered at this or that time of year, in this or that constitution of the Air.

And therefore though all Honey is sweet of it self; yet sometimes both its Taste and Smel is changed, according to the Nature of the Plant from which it is gathered: and therefore it is sometimes Venemous, when it is gathered from venemous Plants. Whereof see *Pliny Lib.* 21. *Nat. Hist. Cap.* 13. *Dioscorid. B.* 2. *Cap.* 74. *and Book* 6. *Cap* 8.

This same Honey is twofold, Manna called also Air-Honey, or Dew-Honey, and which in a special manner is called Honey. For Manna is a Honey or Dewy Humor, mixt of a vapor and the Subtile and Fat Exhalations of Plants. and by the temperate coldness of a clear night congealed; sticking upon Plants, Stones and other things near the Ground; which at first is more liquid, and afterward the thinner parts resolved it becomes harder, and having attained its consistency, it is coagulated into certain grains. For although some hold, and among them *Christophorus a Vega Lib.* 2. *de Art. Med. Sect.* 3. *cap.* 11. That Manna is the work of certain smal bees resembling large Gnats, from which Bees sitting in swarms upon the Trees the Manna drops down like sweat: yet most likely it is, that these smal Creatures are rather drawn thither by the sweetness of the Manna, then that they make the same. There is much bred in the East, because of the purity of the Air and a certain moderation of heat and cold in those parts. 'Tis not bred in cold places: there is little bred in *Italy*, save in *Calabria*, from whence it is carried as a commodity into other parts. *Two sorts of honey.*

Now whether that Manna wherewith the Israelites were fed fourty years in the Wilderness, was the same with this of ours, Authors vary. *Vallesius* in his *B. de Sacra Philosoph. chap.* 57. and other later writers hold it was the same kind of thing. Many things said of that Manna of the *Hebrews*, *Exod.* 16. *Numb.* 11. do also agree to this of ours: yet herein *that* disagrees from ours, because thereof, (beaten or ground.) Cakes or Cracknels were made. For our Manna is not of such an hardness. But however herein all agree, that many things which hapned touching the *Hebrews* Manna cannot be attributed to Natural Causes, but only to the infinite power of the most good and great God. *Whether our manna be the same which the Israelites had.*

But vulgar Honey differs little from Manna, and the matter of both is one and the same, save that the matter of Manna is thicker, more compact and Earthy; but that of Honey more subtile and more digested. For Honey is a certain Dew, gathered by Bees, and receiving alteration from the little bladders they have within them, and afterwards stored up by them in little cells in manner of a pure Liquor, wherein afterwards it works like new Wine; and is by its Natural heat concocted, and grows thick, as *Aristotle* relates in his 5. *de Histor. Animal. Cap.* 22. and *Pliny* in *Nat. Hist. L.* 1. *Cap.* 13. *Common honey what it is, how differing from manna, & how generated.*

Honey is chiefly gathered by Bees both wild and domestick: Yea and Drones also and other insects, being much of the Nature of Bees, do gather Honey, out of all Herbs which have hollow flowers like Cups, and out of others wherein there is any sweetness: which is done without any detriment to the flowers. You have more of the Nature of Bees and Honey in the same place of *Aristotle*, and in *Plinies B.* 21. *Nat. Hist.* from *chap.* 5. to the 16.

Chap. 9. *Of the Rain-bow, False Suns and Moons, strakes in the Sky, and Circles about the Moon.*

AFter Clouds and such things as are of them ingendred, there remain to be handled certain things appearing in them, called *Phantasmata*, apparitions; such as are the Rain-bow, the Halo or bright Circle, and other like Images. And to begin with the *Iris* or Rain-bow, which they say hath its Name *ab Eirein* to tel, because it foretels Rain or Fair weather, (and therefore it is by Poets termed *Junos* Messenger,) It is a bow of three colors, in a Dewy cloud, caused by the beams of the Sun or Moon opposite to the said Cloud, and therein retract and reflexed.

What the Rain-bow is?

And that it may be better understood what the Nature of a Rain-bow is, all the members of the definition must be weighed. The subject of a Rain-bow is a dewy vapor, or a Dewy Cloud, which is beginning to be resolved into drops or Rain; but it is not yet Rain, only it is condensed into little drops like dew or the Water which a man blows abroad out of his mouth half shut. For a continued Cloud is not the subject of a Rain-bow; but those parts thereof which do no longer hang together, but being by the cold straitened and condensed are every where distant one from another, divided into very many smal drops, which are like little Looking-Glasses, and are of a middle Nature betwixt a perfect Rain and a Cloud.

The subject of the Rain bow.

Now that the Rain-bow cannot be made in any continued vapor, but that it may be generated in many little round Bodies, is demonstrated from the rules of Opticks concerning the Nature of reflection. We shall only here produce what experience teaches. Let a man stand with the hind part of his Head to the Sun, and with his mouth or other Instrument let him throw water into the beams of the Sun, so that the Water may lose its continuity, and be resolved into very many very smal drops: which being performed, a Rain-bow as it were will appear in those little drops, which represent the rorid Vapor. The same may be observed when the Water is scattered by Oares, or falling violently upon a stone it is scattered into the Sun-beams. And though the rorid Cloud, which is the subject of a Rain-bow, is no longer continued; yet to us it appears continued, by Reason of the Vicinity of the parts, and its overgreat distance from us.

The efficient cause of a Rain bow

The efficient Cause of a Rain-bow, are the beams of the Sun and Moon, broken and reflected in these drops. And that reflexion is altogether necessary to the making of a Rain-bow, hence appears; because both the incident Raies and the refract do go into the part opposite to the lightsome Body, nor do they pass on to the part seen by the lightsome Body; nor to the sight, which is averse from the lightsome Body in such as behold the Rain-bow, can they come, unless they be reflected. Therefore in the same manner, as we see in looking-Glasses the Images of things behind us, even so the raies of the Sun or Moon are reflected in those little looking-Glasses.

Howbeit, 'Tis necessary that there be also refraction. For when as a Ray of the Sun or Moon comes to the first drop of the Vapor, it pierces the same being through nearness of the Sun not yet much condensed, yet so as that it is refracted. From thence going to another hindermore drop, which is thick enough, it is presently reflected, if no other drop of a rorid vapor stand before the same: but if any such drop stand in the way, the beam is first refracted, and afterwards so refracted it is reflected to our sight. Also many Raies are refracted in many obvious drops; and whiles they fall in, and pierce through divers thinner drops to one thicker, in which they are reflected; then by such a like drop they are again reflected. For every Ray, as wel the incident as the reflect, is twice refract in such a drop. First, Towards a perpendicular line, when it enters the drop; because it fals out of the thinner Air into a thicker Rorid Vapor: afterward, 'tis disjoyned from the perpendicular, when it goes again out of a thick drop into the thin Air.

The Rain-bow therefore is bred, when some rorid Cloud is in making, and begins to be resolved into very many smal drops, and to be condensed into Water:

Which

Which drops are yet nevertheleſs more thin, and not quite turned into Water, ſo as to fall down. For if the Sun or Moone ſhine juſt oppoſite thereupon, the lucid beams being variouſly refracted in theſe drops, and reflected to our ſight in form of a Pyramid, their light being confuſed and mixt with the Heat and ſhadow of the drops, they preſent unto our ſight a coloured Bow.

A Sun & a Moon Rain bow.

Now moſt Rain-bows are cauſed by the Sun, few by the Moon. And therefore *Ariſtotle* tells us, that in the ſpace of fifty years there were but two Moone Rain-bows ſeen. For to the making of a Moon Rain-bow, beſides a fitting vapour, 'tis requiſite that the Moon be in the full; otherwiſe its beams are too weak; alſo that it be near the Horizon: al which do ſeldom fall out. In the Year 1599 foregoing, at Mid Summer, after great Thunder, Lightning, Thunder-Bolts and Rain in the Night, betwixt the North and Eaſt we ſaw a remarkable Rain-bow, which might compare with ſome Sun-Rain-bows, in the Brightneſs and Beauty of its Colours. Now why only the Sun and Moon make Rain-Bows, the Reaſon is, becauſe the beams of theſe Stars only can reach Croſs the Horizon to the Clouds, and be from thence reflected; thoſe of the Sun becauſe they are moſt ſtrong; thoſe of the Moon becauſe they are near at hand. But the Beams of the other Stars are either too weak or too far off. Or if they be ſo ſtrong as to be able to reach croſs the Diameter of the world to the Clouds: yet are they not ſo ſtrong as to be reflected to our ſight. For reflect Lights are weaker then thoſe that ſhoot their Beams directly, according to the Rules of Opticks.

why the Rain bow is made only by the Sun and Moon.

Now why only the Colours and not the Image of the Sun or Moon appears in theſe Looking-glaſſes, there is a Threefold Cauſe. Firſt, becauſe the Cloud is not a continued Body, but reſolved into very little drops or Optick Glaſſes. For in ſo ſmal Glaſſes the Images alſo are very ſmall, which being afterwards reflected are ſo weak, as that they appear not diſtinct, but confuſed. Againe, the Raies are of themſelves weakned before they come from the Luminous Body to the ſight. Finally add hereto the blackneſs of the Cloud. For the rorid vapour, becauſe it begins to be reſolved into water, aſſumes a certain blackneſs and Watry Colour, which being mingled with the Light, makes that the Image of the Sun or Moon cannot diſtinctly appear, but rather a Colour.

why only colors and not the image it ſelf of the Sun and Moon appear.

Now the diverſity of Colours in the Rain-bow ſprings from hence, becauſe ſome raies enter more deeply into the dewy Vapour, and are reflected by the remoter droplets, others are reflected from meaner vapours and reſting in the ſurface of the Cloud, by which are made divers reflexive pyramides, having baſes equally diſtant. Now the Colours are three, red which is the upmoſt, or outmoſt, and is bred of the greater ſplendor, and the raies of that reflexive pyramid, whoſe baſis is of all others neareſt our ſight: and therefore its Raies are alſo ſtrongeſt. Now becauſe the Light is bright ſhining, and the Water blackiſh, the Colour appears neither white nor black, but a reddiſh Colour betwixt both. The next Colour is a Leek-green; which is the middlemoſt in the Rain bow, this is cauſed by the Raies reflected from a more deep part of the vapour; and therefore it inclines more to blackneſs. For the Raies alſo themſelves are weaker, becauſe reflected from a place more remote; and that vapour becauſe it is farther from the Sun, is more compact, and comes nearer to the Nature of Water then the former. Hitherto alſo the ſhadows do very much contribute, which are ſhed from the former droplets or ſmal glaſſes upon the hindermore, with which the raies reflected from the hindemore are mingled. Of which we have an example in the colours that are in the necks of Doves, ariſing from the Sun-beams. For theſe colours are bred from the ſhadows that being ſent from the Feathers are mingled with the Suns light. The third is the Purple, which is the internal, and ariſes from the Raies reflected from a place yet more remote; and for the ſame reaſons why the Second is blacker then the Firſt, the Third is blacker then the Second.

The Colors of the Rain bow.

And although there may be more then theſe three Colours in a Rain bow; yet becauſe for the ſaid Reaſons the Blackneſs is more and more increaſed, after the third no Colour can be perceived: and not only the reflected Raies are ſo weak that they cannot reach to our ſight; but the Light alſo is ſo darkned by the Blackneſs of many ſhadows, that it is hardly diſcernable by the ſight. Now the fourth Colour which they call yellow, and is ſeen betwixt the firſt and ſecond, is no new Colour, but ariſes from the Neighbourhood of thoſe two. Now the

Lunary

The Moon Rain bow whiter then that of the Sun.

Lunary Rain-bow is whiter then the Solar: becauſe the Light it ſelf of the Moon is paler then that of the Sun; again, becauſe the ſhadows which are by the fore-more drops caſt upon the hinder more are not ſo obſcure and dark, as thoſe caſt by the Light of the Sun. For the ſhadow of a ſtronger Light is blacker, and contrariwiſe. Add alſo hereto the darkneſs of the night. For that which is of its own Nature Blackiſh, if it be ſet by a more black thing, it appears whiter.

But why the Circumference only of a Circle appears and not the whole and entire Body thereof, the cauſe is: foraſmuch as that part only of any irradiated Body is ſeen, from which the Raies are reflected to the ſame centre of ſight, according to equal Angles, and of a radiated cloud nothing is ſeen but what is carried by Raies collected in the ſame point of the Axis wherein the ſight is. But theſe do only make a bow, as the Teachers of Opticks do at large demonſtrate.

why the Rain bow never makes a perfect Circle.

Now why the Rain-bow never makes a perfect Circle, but either a Semi-circle, or an Arch leſs then a Semi-circle; and that it is a Semi-circle when the Luminary is in the Horizon, but an Arch leſs then a Semi-circle, when the luminary is above the Horizon; & that the Arch is ſo much the wider, by how much the Luminary is nearer the Horizon; and ſo much the leſſer by how much it is nearer the Meridian; the reaſon thereof is, becauſe the Centre of the lucid Body, of the ſight, and of the Rain-bow, are alwaies in one and the ſame right line. And therefore the Centre of the Luminous Body being placed in the Horizon, in the oppoſite part of the Horizon will be the Centre of the Rain-bow, and ſo there wil be a Semi-circle above the Horizon. But when the Sun is elevated above the Horizon; the Centre of the Rain-bow is on the other ſide depreſſed; and therefore that Segment of the Circle which is beneath the Horizon is greater becauſe it contains the Centre, and that above is leſs. For we ſee only thoſe things which are above the Horizon. And by how much leſs of the Diameter of the Rain-bow is above the Horizon, ſo much the greater is the Circumference of the Circle; and a Semi circle is half of the leſſer Circle of any Arch whatever that is greater, which proceeds from the Refraction of the beams: becauſe about the Sun-riſe the Air and vapors are thicker, which afterwards by the directer beams of the Sun are attenuated. And therefore the Rain-bow which is ſeen through a thicker Medium, appears alſo larger. But I paſs over theſe and other things which might be ſaid of Rain-bows, ſeeing they cannot be rightly explained without optical demonſtrations and many Diagrams, which muſt be here for brevities ſake omitted. They may be ſeen in *Ariſtotles* 3. *de Meteor Ch.* 4, 5. the writings of optical Authors, and in the learned Treatiſe of *Johannes Fleiſcherus, de Iridibus*, wherein he comprehends the Doctrine of *Ariſtotle* and *Vitellio* concerning Rain-bows, and augments the ſame with neceſſary demonſtrations.

Falſ Suns.

Of kin to Rain-bows are the falſe Suns, or other Suns placed by the true Sun. Now the *Parelios* or falſe Sun, is the Image of the Sun, received in a Cloud continued, compact, equal, ready to turn to Water, in its forepart Tranſparent and Poliſhed as it were; in its hinder part dark and terminated, and placed obliquely by the Suns ſide, and reflected thence to our ſight. For look as if a man ſhould ſet a Looking-Glaſs ſlanting by the ſide of any thing, he will twice ſee the Image of the thing: ſo if a Smooth cloud like a Looking-Glaſs be ſet aſſant beſide the Sun, there will appear divers Suns. But *Pliny* writes that to his time there had never been ſeen more then three at once, *Hiſt. Nat. B.* 2. *Ch.* 31. Howbeit they report that ſix were ſeen at *Papia*, before the War. Now theſe falſe Suns ſeldom appear, becauſe there is ſeldom found a cloud that hath ſuch a diſpoſition and ſuch a Poſture to the Sun.

The Paraſelene or falſ Moon.

After the ſame manner is cauſed the Paraſelene or falſe Moon, which herein only differs from a Parelios, that the former is an Image of the Sun, this latter of the Moon. Now the Images of theſe two Stars only are reflected to us; becauſe their Raies are the ſtrongeſt. Yea and a falſe Moon never appears but when the Moon is in the ful, when her Light is moſt plentiful and ſtrong.

Rods, and ſtrakes in the Sky.

Hither alſo are to be referred the *Virgæ* or Rods ſo called, which are as it were certain lines and long Pillars, which appear of divers colors, in an uneven cloud, placed on one ſide of the Sun, ariſing from the beams thereof refracted. For ſuch ſtraks are ingendred, when an uneven cloud, which hath ſome parts thicker and as it were of a wateriſh Nature, and others thinner, is placed beſide the Sun. For when the Sun-beams fall thereinto, they cannot pierce equally becauſe of the diverſity of

the

the parts; nor do they appear contiguous, but rather disjoyned, and in the hinder parts, through which they penetrate, refracted; and so they represent divers colors: after the same manner as the Sun-Beams coming through chinks into a close Chamber, they represent lightsome Lines. Now the colors are not the same, but various according to the divers disposition of the parts wherein the Raies are received, which in thinner parts appear more light and white, in thicker more black and dark. Now these Rods or Strakes do appear for the most part, when the Sun rises or when he sets, but never at Noon tide; for then his Beams are so strong, that they easily attenuate and pierce into thickest Vapors.

Finally, There is seen in the Clouds the *Halo*, which is by the Author of the Book *de Mundo* thus defined, *Cap. 4. Halo* is a shining Circle, under the Sun, Moon, or other clear Star, appearing just betwixt us and the Star, made by the Beams thereof there refracted. For this same Circle is made when the stronger beams of some Star fal into a cloud equally spungy, which in regard of the Spunginess can indeed pass through, yet are refracted therein because of the thickness of the Air, and being refracted to even Angles they make a Crown. Now in the Center of the Crown the Star appears which is the cause thereof; because the straight Raies are stronger, and do more attenuate, Rarifie, and Illuminate the cloud. Now this kind of Crown appears most commonly a nights. But the vehement heat of the Sun dissipates the Vapor, and makes it more rare, so as it is unfit to refract the Sun-beams, by which means such a colored circle might arise. Now the Sky must be calm, that the *Halo* may be seen. For a cloud moved and variously agitated can neither retain an equal disposition of parts, nor present a certain color by the refracted Raies.

Halo the Circle about the Sun, Moon &c.

Chap. 10. *Of Fountains.*

But that we may at last finish our Doctrine of Meteors, let us speak somwhat in the last place of Fountains and of the Sea. The opinion of *Aristotle* is commonly known touching the original of Fountains: how that Air and Exhalations in the Caverns of the Earth do by the coldness of the place lose their heat, grow thick, and are turned into water: after the same manner as in the middle Region of the Air, of vapors condensed, Rain is ingendred; which afterwards descending, and from many places gathered into one, and there flowing out become a Fountain: whose continual running is maintained by new Air daily succeeding in the Room of the former to avoid Vacuity, and afterwards changed into Water.

Aristotle his opinion of the original of Fountains.

But in good deed if we understand this Opinion of his concerning all Rivers, it is not true. For though we should grant that some Water may be made of Vapors condensed in the Caverns of the Earth, and that this may haply give beginning to some Fountains: yet we cannot be brought to think, that so much Water is this way generated, as to supply all the Fountains and Rivers that run upon the Earth. For since it is apparent, how great a Quantity of Air is required to make a little Water, and how much space those vapors take up of which a little Rain is bred; where will there be so many and so large Caverns, wherein so many Vapors, and so much Air, can be collected for the production of so many and so great Rivers? Also a reason of the perpetual Course of Rivers can hardly be rendred according to this opinion; seeing there is not alwaies the same plenty of Vapors. Much less can a Reason be given why many Fountains Issue from the tops of the highest Mountains.

Let us therefore rather embrace that opinion which is the most ancient of all, which the Preacher in *Eccles.* 1. *v.* 7. comprehends in these words: *All Rivers run into the Sea, and the Sea Flowes not over; the Rivers return to the places from whence they came, that they may flow again*; And let us hold with very many most learned men, that Fountains and Rivers as they run into the Sea, so have they their Original from thence. For otherwise the continual running of Rivers cannot be made forth, nor a cause be given, why the Sea receiving perpetually so many Rivers runs not over: or how Fountains come to arise from the tops of highest Mountains. And unless

The true opinion.

Why the Sea flows not over.

unless the Rivers had their Original from the Sea, it could not be but the Sea must run over. For the Rivers have some proportion to the Bulk of the Sea, seeing some of them are poured with such violence and in so great plenty into the Sea, that for the space of many miles together they afford in the Continent sweet Waters to the Mariners, amidst the Sea Waters. Nor can the Sun or Winds consume so much thereof as doth flow in; but the Sea repairs its detriment which it receives in common with the Rivers from the Sun and Wind, out of the Air, in the Nights. Also many Fountains have many things common with the Sea. *Pliny* writes in *Nat. Hist. Book* 2. *Ch.* 103. of Jupiters Fountain in *Dodona*, that it was alwaies dry at Noon; and from thence the Water encreased, till at Mid-night it overflowed, and after that it deceased by little and little. And he relates *in the same place*, How that overagainst the River *Timavus* there was a smal Island in the Sea, with hot Fountains in it which Ebd and flowed as the Sea. Nor doth *Plato* seem to have been averse to this Opinion, who in his Dialogue called *Phædo* writes, that there is an hollow place in the Earth, into which all Rivers run, and out of which they run back again.

Why Fountains arise from the tops of highest Hills?

Hence also a cause may easily be rendred, why Fountains arise on the highest tops of Mountains. For since the Globe of the Earth is round, and the store and weight of the Sea Water is great: it may easily by its weight thrust the water which flows through the veins of the Earth into the highest Mountains. And whereas the Fountain waters are not Salt, though the Sea is Salt, and that they have great diversity in qualities, springs from hence; because the Sea Water being strained through many turnings and Veins in the Earth, loses its saltness, and receives other qualities out of the Caverns of the Earth through which it runs and flows. Now the difference of Fountains is great; for some are used instead of drink, and others for Physick. The former are more simple, the latter more compound.

Mineral waters what?

Metalline or Mineral Waters are those, which have in them the spirits or smallest particles of Minerals, Metals, and Subterranean Juyces, and differ from other ordinary potable Waters, in Smel, Tast, Color, and therefore are not used for drink, but only as Physick. Now these Waters are of two kinds; some have in them the very Bodies of Minerals and Mineral Juyces, such as are Salt Waters, vitriolated Waters, Alum Waters, out of which the water being boiled away, Salt, Vitriol, and Alum are drawn; nor may they conveniently be used as baths. But some contain in them the Spirits of Metals, and therefore in regard of the very great active and penetrating Faculty which they have, they are Medicinally used, both to drink and to Bathe in; such are the hot Baths, the acid and brackish Waters.

They are twofold.

whence metalline waters have their virtue.

Now whence these Waters have their faculties, Authors are not agreed. Some conceive they have their Virtue from the Minerals and Metals through which they flow. But this is not likely to be true. For since the Bodies of Metals are so compact, the Water which flows over them cannot so easily draw in their Forces; and if Mineral and Metalline Waters did thus gain their Virtues, we should have more of them. This indeed is true, that Minerals, as Vitriol, Alum, and such like, are corporeally mixed with the Water; and therefore they are separated from the Waters by boyling: Howbeit those Waters wherewith the Minerals are mixed only Bodily, do not gain those Virtues which the true Mineral Waters have, out of which the Metalline Bodies cannot be separated. But Metals cannot communicate their Faculties to Waters, only by the Waters running over them.

And Experience doth witness that many springs breaking out of high Hills do bring out with them Gold, Silver, Copper, Iron, Tin, Lead, *Lapis Lazuli*, the Armenian Stone; and yet they have no faculty of any of those Metals which they carry and drive forth, but may be drunk as ordinary Waters.

Moreover if those Waters should gain their Virtues only by washing the Metals in their Course; the Virtues of the next Veins through which they flow had been long since exhausted: whereas nevertheless these Waters have had the same Virtues for many Ages together, and do still retain the same. Moreover out of those metalline Waters no Metals can be drawn forth, either by distillation, boyling or any other way.

Most

Moſt likely therefore it is, that thoſe waters take their Virtues from the firſt matter of the Metals, which is a ſubtile, Fluid, and ſpirituous ſubſtance, not yet compacted nor coagulated into a ſolid Metalline Body. For theſe ſpirits of the Metals are mixed with the waters, and communicate all their Virtues to them. For as out of Vitriol, Sulphur, Yea and Metals themſelves, by force of Fire ſpirits are drawn, which being mingled with water do communicate their Virtues thereunto: even ſo Nature alſo, in that great Circulatory the Earth, in the generation of Metals produces ſpirits, which being mixed with neighbouring Waters and ſuch as run by, do beſtow their Virtues upon them.

The Cauſe of the heat of Baths.

Nor doth a leſs difficulty occurre in ſearching the Cauſe of hot Baths. Some attribute the Cauſe to the Suns heat, others to winds gathering hot Exhalations into one place: but without any probability. Others think they have their heat from the *Lapis Calcarius* or Chalk Stone ſo called. But neither is this probable. For the *Lapis Calcarius* doth not heat water unleſs it be firſt reduced into Lime by Fire. And ſuppoſe that thoſe Stones were Calcined by the Fire under ground, yet could not that heat be perpetually continued. For after that the Lime-ſtone is once ſoaked in Water, it will afterward no more become hot.

Others therefore do more probably deduce the cauſe of the heat of Baths from the Fire which is in the Bowels of the Earth, and that the Waters do either run through thoſe hot places underground, or that in the way they are joyned to the Fire and flame, or that they run ſo long near or over the Chanels of Fire, as to grow hot thereby; or whiles the Earth is made hot by ſubterranean Fires, many Vapors are from thence lift up, which at laſt in ſome wide place turn to water, and ſome where or other ſeek their way out. Which they declare by this example. Let ſalt water be mixed with Potters Clay, and make a round Globe of the ſaid Clay, hollow within, whereinto put a Pipe, and ſtop the hole with Clay whereinto the Pipe is put; then put the Globe upon the Fire, with the Pipe from the Fire. When the Globe Waxes hot, hot Salt Water will flow out of the Globe through the Pipe.

Howbeit, ſome there are, who though they allow this manner of generation in many places; Yet ſeeing in all places where there are hot Baths there are not ſigns of any Subterranean Fire; and moreover there are Baths found, whoſe heat vaniſhes away, if you dig a little to find their original: wherefore they conceive it probable, that ſome hot Baths are cauſed by two or more metalline Waters, which are cold to the touch, of their own Nature, but upon their meeting together they grow hot by the Repugnancy of Spirits. An example whereof is ſeen in ſpirits of Vitriol and Oyl or Salt of Tartar; alſo in *Aqua fortis* and Tartar, Butter of Antimony and Spirit of Nitre: which though to the touch they are cold: yet if they are mixed they grow hot; and that in ſuch a meaſure, as if ſuddenly you pour Oyl of Tartar upon *Aqua fortis* wherein Iron hath been diſſolved, it will not only boyl but take flame: which alſo will happen, if you ſuddenly pour a quantity of ſpirit of Nitre upon Butter of Antimony ſo called. And therefore they conceive it rational, that when two ſprings conſiſting of a mixture of ſuch Repugnant ſpirits do meet and mix together, that the water ſhould by that means wax hot.

The Cauſe of the Seas Saltneſs.

Now concerning the Sea, Authors are wont in the Doctrine of Meteors to handle two queſtions principally, one concerning the Saltneſs of the Sea, another touching its Ebbing and flowing. Touching the Seas ſaltneſs the opinions of the Ancients were many, which *Ariſtotle* refutes in his 2. *Meteor. Cap.* 3. We in this point follow *Ariſtotle*, and hold that the Sea water is not Salt of its own Nature, but that it becomes ſuch by the admixture of ſome Salt thing; which alſo is ſeen in Ley. Which alſo may be gathered from that which *Ariſtotle* in the *forecited place*, and *Pliny* in *Nat. Hiſt. Lib.* 31. *Cap.* 6. deliver, how that hollow balls of Wax let down by Nets into the Sea, and empty veſſels ſtopped, they gather into themſelves freſh Water. For many Earthy Salt Exhalations do both fal into the Sea in ſhowers, and flow thereinto with Rivers: alſo the Sun exhals out of the Sea the moiſter and ſweeter parts of the Water, leaving behind the more heavy and Earthy. And therefore on the top the Sea is ſalter, then towards the bottom, becauſe the Sun doth more exhale the ſweet parts out of the Surface: alſo the Sea is ſalter in the Summer then in the Winter, and more in the Eaſtern and Southern parts then elſewhere; becauſe in thoſe places the Sun beams are ſtronger.

The Ebbing and flowing of the Sea how caused?

As to the Ebbing and flowing of the Sea, there is very great difficulty, chiefly caused by the very great variety which is in the said Motion. For in some places there is no such motion, or it is scarce discernable: in other places it is so great, that vast shores lie bare, and there are places to go over dry, which were before covered with Water: in some places the motion is slow, in other places so quick, that in the space of an hour or two many miles will be covered with the Flood, and as many bared by the Ebb, so that men can hardly run fast enough to save themselves from the fury of the Tide coming in. Nor doth this motion keep the same time in all places. For the most part, it flows six hours and Ebbs as many. Yet in some places is flows seven hours and Ebbs five: in others, it flows four hours and Ebbs eight. In which Variety nevertheless there is this regularity, that the Ebbing and flowing together last but twelve hours. In very many places the greatest floods are at full moon; yet in some places they happen at new Moon. Touching which variety of this Motion, you may read in *Cardan, Lib.* 2. *Subtil. p.* 168 *Scaliger* in *Exercit.* 52. *Caspar Contarenus* in *Lib.* 2. *de Elementis. Collegium Conimbric. de Met. Tr.* 8. *Cap.* 4.

Now touching the Cause of this motion there are so many several opinions, that you can hardly tel which to assent unto. Wherefore not without Cause *J. C. Scaliger* in his 52. *Exercit.* thus writes: *My common saying which I use every where, That we know nothing, is most seasonable in this disquisition touching the Motion of the Sea.* And a little after. *Who will not say that Philosophy her self can but stutter in this point? When he shall see almost in the same shoars, that it is high-water at* Calicut *when the Moon is full, and at the shoars of the River* Indus, *when the Moon is new. This is a point of subtilty which thou oughtest to have searcht into, O* Cardan; *which if thou canst unfold unto us, I will consent that thou be counted the god of Philosophers. You will ask me, what say you to the matter? I? I did nothing but expect to hear from you. But seeing you appear not in this Point, I dare not so much as expect my self.* And therfore if so great a Philosopher doth here confess his own Ignorance, what can we promise after him save to reckon up the opinions of some Authors.

Julius Cæsar Scaliger therefore attributes the force hereof to the Moon, and divides half the Heaven which is turned about in twelve hours, into two Quadrants, and that during the one the Waters do follow the Moon to the middle of Heaven six hours, and as many more they fall back, being driven by the repulse of the shoars. But whether the encrease of the Sea be caused by rarefaction, or by addition of new substance, he dares not determine; only he saies, the Sea Waters do follow the Moon, and that they are suspended thereby as the Iron by the Loadstone. And herein most Authors are agreed, that the Motion of the Seas Ebb and flow depends upon the Moon, and that it is terminated in twelve hours. And that because the Moon doth not alwaies rise in the same place, nor is also alwaies at the same time carried above the Horizon, therefore the Ebbing and flowing doth not observe the same time. Now that this motion depends on the Moon, besides what hath been said, this seems also to be a sign, *viz.* That the Flood comes every day an hour later; because the Moon returns to the same place in about the space of twenty five hours. Now *Scaliger* in the same place endeavors to render a Reason of that variety, of swiftness, and Cessation in some places, and of other things seen in this Motion; from the various Scituation of places, the highness and lowness of the shoars, the greatness and narrowness of the Sea, the even Plainness of its Course, or the many turnings, windings and straits, and the Nature and depth of the bottom.

Contarenus conceives, that when the Sea flows the waters are rarified and so swel and are on all sides poured out to the shores; and that in the Ebb the Waters are condensed and contracted into themselves and so leave the shoars; and that the rarefaction proceeds from Heat, the force of which heat depends upon the Moon. And to explain the time of this motion, he divides the Heaven into four equal parts, with the two greatest Circles, the Meridian and right Horizon, upon which when the Moon ascends towards the Meridian, the water swels and is poured abroad; for then the beams of the Moon have greatest force: but when the Moon is moved from the Meridian to the occidental Horizon, the water flows back again, and gathers it self into it self, because of the weakness of the Raies of the Moon. But why,

when

when the Moon is moved from the Occidental part of the Horizon, unto that part of the Meridian which is beneath the Horizon, the Water should swel again, and afterwards decrease when the Moon goes from the Subterranean Meridian to the oriental Horizon, he saies he can find no probable cause himself, nor can see any made out by others. Also he professes the Cause is to him unknown, why in some places there is no Ebbing or flowing of the Sea.

Taurellus holds thus: The Sea disburthening it self into the inmost parts of the Earth, is the cause that the Waters with great violence flow from all the shoars round about to that Gulph or inlet. For there where the Sea empties its Waters into the Cavities of the Earth, there also it is depressed and fals, that the other Waters may from all parts creep thither, which (the Caverns of the Earth being filled) being gathered from all sides into one place, according to the Largness of the Sea and the force of the Waters it is raised aloft, and afterward settles by degrees, and returns to the shoars formerly forsaken, an addition also of Waters being made from the Rivers. Thus the whole bosome of the Sea is filled with Waters, til the upper Cavities of the Earth being emptied they require more Water of the Sea, to swallow up after the foresaid manner.

THE FIFTH BOOK.

Of Minerals and Metalls.

Chap. 1. *Of Earths:*

After Meteors, we are next to discourse of Bodies perfectly mixed. Now Bodies perfectly mixed are of two sorts: some lifeless, others living. The lifeless are Metals. For by that word all things bred in and digd out of the Earth are understood, as appears by the preface of *Dioscorides* to his Fift Book. Late Writers call them in general Minerals: because the Quarries and Pits whence they are digd are termed Mines.

whence Minerals have their forms?

Now concerning the Nature of all these kind of things, this is first to be known; that many men conceive, that these Minerals and Metals contain nothing in them besides Elements, and that they are only simply mixt bodies; but herein they are mistaken. For their operations are of a far other Nature, then that they can be deduced from the Elements alone. And therefore *Scaliger* saies rightly in his *Exercitation* 137. *Sect.* 20. That *every forme of a perfectly mixt Body, although it is no Soul, (as for example that of an Adamant) is a fift Nature far different from the four Elements.* And in his *Exercitat.* 101. *Sect.* 14. he reprehends *Cardan* for beleeving, that only by the mixture of the Elements it can come to pass that the Load-stone can draw Iron. For even these things have also, that I may so speak, their Seminary forms and Virtues, put into them by God at their first Creation; nor were they made after the Creation of the world, by the various conflict of the Elements, but were created by God; and by those forms they are perpetua-

red,

ted; and from those forms proceeds not only the forming of their Bodies, (which is no less admirable then in some plants,) and their wonderful Virtues, but also their Propagation and Perpetuation. For the form of Minerals and Metals can multiply it self; and those Bodies have in their Creation a power given them by God to multiply themselves in a fitting matter and a convenient place. Which even Nitre doth teach us. For though out of Nitrous Earth the Salt be once extracted by boiling: yet out of the Mother of Nitre, as they call it, new Nitre is generated; and that not once only, but very often; which our Salt-peter men now a daies know very well. Nor was it unknown to the Ancients, as appears from *Pliny*, *B.* 31. *Cap.* 10. where he writes, that the froth of Nitre was made, when the Dew had fallen, the Nitre Mines being Pregnant, but having not as yet brought forth. By reason of which form it comes also to pass, that though in these Minerals there is a mutation in their external form, so that they are reduced into Pouders, or Liquors, or Glasses: yet they nevertheless eafily returne into a Metalline Body; because their internal form continues safe and sound, as may be seen in Mercury, Antimony, Lead and other things. And therefore when the Question is touching the Generation of Minerals and Metals; it is not enough to have recourse to those Vapors mentioned in the Doctrine of Meteors, but there is need of more determinate and Specifick principles.

Now what these are, cannot in general be wel explained. For there is great variety of Minerals, which must first be propounded. Now they are by others otherwise divided. I think fit in this place to retain the division of *Albertus Magnus*, who makes three kinds of them, Stones, Metalls, and Middle Natur'd Minerals; by which Name he comprehends all the rest, which have a certain middle Nature betwixt Stones and Metals.

And that we may begin with the last kind, it contains many things under it; Earths, Stones, Sulphurs, Bitumens, and some things mixt of these, coming nearer the Nature of Metals. As for what concerns *Earths*, we do not thereby understand the simple Element, nor yet that Earth which is every where plowed up by Husbandmen, and which is fit to sow Corn and to set Herbs in: which though it be not simple, yet it comes nearer to the Nature of the Element of Earth, then the Metalline Earths do. Although here also is great variety, and some ground partakes little or nothing, another partakes much of a Metalline Nature. Now that many grounds partake much of Minerals doth hereby appear, in that when they are burnt they send forth a Sulphureous Vapor, as Metals and Minerals are wont to do. But by earth in this place, we understand a Body digd out of the ground, which partakes of a Mineral Nature, and which (water being thrown on it) dissolves, and turns to Clay.

Potters Clay and Argilla. Among these kind of Earths the most vulgar is Argilla and Potters Clay; which is a Clammy Earth, and breaks not when it is molded, nor chops when it is dried. There is also great variety hereof, according to which the Vessels differ, which are made not only for Kitchin uses, but for other House occasions, and for the use of Gold-Smiths that melt Metals, and for Chymists. For of every kind of Clay all Vessels cannot be made, and one sort will endure the Fire better then another: also one sort wil be molded more delicate, thin and fine then another. Whence the excellency of Potters Clay is estimated.

Marga, Marle. After Argilla and the several sorts of Potters Claies comes *Marga* or *Marle*. Now this is a Fat Earth, being as it were the fatness of the ground, and the name comes from the High-Dutch, and 'tis called *Steinmarck*, as if you would say the Marrow of Stones; and it is found shut up amongst Stones. Now there are sundry kinds thereof; *Pliny* reckons six, White, Red, Dove coloured, Clayish, Stoney, and Gravelly. And of each of these there are again many different sorts. 'Tis found in many parts of Germany, and among them the *Marle* of *Rochlich* is most famous; which they use in the stead of Bole-Armeniack.

To Earths also belongs *Creta* Chalke, by which name also Earths are understood, which are used to Polish, Clense, Rub, Paint and Colour. There are many kinds thereof, yet because it is chiefly digd up in the Island of *Creta*, therefore all sorts have borrowed their Name from it.

There are also many other kinds of Earth, which are used partly by Physitians, partly by other Mechanical Artists, which differ in Rarity or Spunginess, in Clamminess,

mineſs, in colour, taſt and uſe. And as to their Medicinal uſe; ſome binde cool and dry, as the Eretrian, Samian, Lemnian, Armenian: ſome with their aſtriction have a certain biting quality, either from Nitre, as the Chian, Selinuſian, Cimolian, and *Pignitis*, which are Abſterſive or Scouring; or from Alum, as the Melian Earths, and the Clay of many Baths, which are good for the Gout and Malignant Ulcers: or they have in them ſome quantity of Bitumen and of Sulphur. Alſo there are ſome Earths which give a black Tincture fit to make Inke, as *Calcitis*, *Myſi*, *Sori*, and *Copperas*.

The moſt renowned among theſe Earths are *Terra Lemnia* and Bole-Armeniack. The former is ſo called from the Iſland wherein it is found. Alſo it is called *Terra Sigillata* or ſealed Earth, from the Seal imprinted thereupon. *Galen* avers that he ſaw with his own Eyes a certain hill near the City *Epheſtiades*, wherein no plant grows, the ſoil being as it were burnt up, of a red colour, out of which the Earth is digd. Alſo that there were three differences thereof: that one was of a red colour, but not ſtaining the hands, being the moſt excellent of all, which the Prieſt might only touch, as a ſacred thing; and he ſealed it with *Diana* her ſignet, which was the Picture of a Goat: the other was red Oker which did colour the hands of the touchers; the third was uſed to ſcour Cloathes, becauſe of its cleanſing faculty. Thoſe who at this day ſail to the Iſland of *Lemnos*, do ſay that it is gathered in the Dog-daies in a mooriſh ground, that it is ſigned with a certain Seal and ſent to the great Turk, and that therefore it is hard to come by, and not publickly ſold. But theſe ſealed Cakes have not all the markes of the old *Terra Lemnia*. Now the old *Terra Lemnia* had an excellent Faculty to reſiſt the Plague and Malignant Diſeaſes. *Terra Lemnia Sigillata.*

Bole-Armeniack or Earth of *Armenia* was brought out of that part of *Armenia* which is next to *Cappadocia*. It was of a pale colour, would quickly be reduced to fine powder like as Chalk will, being held in the Mouth it would melt like Butter: it was drying and binding; and therefore it was uſed for the *Dyſentery*, the looſneſs of the Belly, and ſpitting of Blood; for Catarrhes, and Ulcers of the Lungs: alſo it was good againſt the Plague. *Bole-Armeniack.*

Moreover there are many other Earths, *Eretria*, *Samia*, *Selinuſia*, *Chia*, *Cimolia*, *Pignites*, *Melia*, *Rubrica*, and *Sinopica*, Precious Earths ſo called moſt of them from the places where they were digged. Of which ſee *Pliny* Book 35. Ch. 16. and 17.

And indeed the Ancients uſed ſuch Earths as were then known to them, and were brought out of neighbouring places; and ſeeing we have hardly now any certain notice of many of them, and the Quarries of the Ancients by injuries of time and the change of Empires are either unknown or exhauſted, and every where in other places and in our Countries the like Earths are found: it is better to aſcribe the Virtues of theſe Earths to the kind then the place, and to value every one according to its own Nature, and to try the Vertues of Earths by Experiments.

For there is in *Hungaria Bolus Tockavienſis*, which *Crato* in his Epiſtles tels us that it will melt in the Mouth like Butter, and hath all the ſigns of true Bole-Armeniack, and is very good againſt Catarrhs; and he prefers it far before the Bole-Armeniack which we have at this day, yea before that which was brought the Emperor out of Turky. He ſaies he found by experience that it holp many of the Plague at *Vienna*. *Bolus Tockavienſis.*

Moreover there is the *Terra Sigillata* of *Sileſia*, which is preferred before the *Terra Lemnia* and the Turkiſh Earths which we have at this day. For it is now proved by many experiments, that it hath rare Virtues againſt the Plague, Malignant Feavers, the bitings of Venemous Beaſts, the looſneſs, and the Bloody flux. The Chymiſts call it *Axungia Solis*. The finder out thereof was *Johannes Montanus* a *Sileſian*, who publiſhed a Writing or Treatiſe concerning the ſame, how that Gold was changed by the ordination of God and Provident Nature into a moſt excellent prepared Medicine, eſpecially good againſt Poiſons, no leſs then thoſe Medicaments which are made with great Coſt of Hungarian Gold. And if that be true, I wonder why it is diſſoled rather with Spirit of Vitriol then Spirit of Salt. *Terra Sigillata of Sileſia.*

There is alſo found another about *Lignitium* and *Gold-berg* in *Sileſia*, which the Chymiſts

Chymists term *Axungia Lunæ*: and in many other places other such Earths are found. And therefore, as I said before, these kind of Earths are not so much to be esteemed according to the places, as their own peculiar Natures. And because they have all their Virtues from Minerals and Metals, when we would judg of the Virtues of any sort of Earth, we must consider with what Mineral or Metal it hath affinity. And now we proceed to other things of this kind.

Chap. 2. *Of Salts.*

AS concerning Salt, there are many kinds thereof. First, There is common Salt: which again is threefold: digd Salt, Sea-Salt, and that which is boiled out of Salt Fountains. Now what the original of Salt is, is not so manifest. 'Tis commonly said to be engendred of a watry and thick Earthy Juyce mingled together. But this doth not sufficiently explain the matter, nor is the cause rendred why it is found only in some certain places. The more probable opinion and most likely is, that Salt as other minerals and Metals, was at the beginning of the World created in the Earth, wherein it stil Preserves and Multiplies it self, by a faculty placed therein by the Creator. For if the simple Elements, in so many Mutations and Vicissitudes of Sublunary things, do preserve and multiply themselves, and so remaine entire, from the beginning of the world to this very day: I see no cause, why we should deny the same power to these Bodies. For that which was before said of Nitre, is true of common Salt. And therefore it is not bred in all places, but in those only where that spirit, (or Seminary principle, if I may so cal it,) is present; as Nitre is bred only in that Earth, in which there is the Mother of Salt-Peter. And from the principle of Salt, in the Caverns of the Earth, where there is no great store of moisture, *Sal Fossilis* or digd Salt is bred. And according as that matter which by the Principle and spirit of Salt is coagulated into a Body, is purer or impurer: so this digd Salt is bred purer or impurer, and some is blackish and dark colourd, othersome is white and transparent like Christal, which is called *Sal Gem.*

The Original of Salt

But if the said principle of Salt be mixed with much humidity and Waters sliding through the Caverns of the Earth; Salt Fountains, out of which Salt is boiled do thence arise. Some indeed conceive that Salt Fountains arise from the Sea. But the Sea Water doth not contain so much Salt in it as many Salt Fountains do; which experience doth teach Nor let any man say, that the Waters while they flow through the Caverns of the Earth do exhale, and are consumed by the underground Heat, and that so some Fountains come to be Salter then the Sea. For if this were so, the Salt Fountains which are farther from the Sea should contain more Salt in them then those that are nearer, which nevertheless agrees not with Experience. Others conceive that Salt Fountains proceed from waters which run through the Caverns of the Earth containing much digd-Salt in them. But, though this cannot be absolutely denied; yet the question is whence that ground Salt hath its Original and Durability. For if Fountains were made Salt only by their Waters flowing through ground-Salt, they would not last so many Ages; but the ground Salt being melted into the Waters would be consumed, but especially those Fountains would not alwaies afford a like quantity of Salt, seeing the Salt being melted by the running by of neighbouring Waters would be washed away. Therfore we must of necessity add the Spirit of Salt, the primary principle of the Generation of Salt.

Sea-Salt is made of the Sea water, the Heat of the Sun consuming the Watry moisture. And if the Heat of the Sun be not sufficient, it is perfected by Fire: and to make it whiter and purer, it is purged by Solution and Coagulation. There are also certain Lakes, which by the Heat of the Summers Sun, turn to Salt, whence we have the Tarentine and Phrygian Salt.

The use of Salt.

The chief use of Salt is to Season Meats, and all the Spice in the world will not make meat pleasant, without Salt. It Heats, Dries, Scours, and consumes superfluous moisture, and therefore preserves from putrefaction. And although it defends from Putrefaction, yet is it not good in putrid Feavers; not only because it is Hot, but because it dries too much.

Beside

Beſide Salt uſed in food, there is another ground-Salt, called *Armeniacus* or *Ammoniacus*, cal'd ſo from *Ammos* the Sand, becauſe it is found under the Sand congealed into plates, in the *Cyrenaick* Countrey. It was of a blackiſh color, and ill-taſted. And therefore it is now adaies out of uſe; and Sal Gem is uſed in ſtead thereof. But that Sal Armeniack which is commonly now ſo called, and which the Chymiſts uſe, is made by Art. It is made of five parts of Mans Urine and one part of common-Salt, and half a part of the Soot of Wood, boiled together til the moiſture be conſumed. That which remains is ſublimed, diſſolved again and coagulated. *Ammoniac Salt.*

This Salt is extreamly volatile, and renders all fixt things volatile, and therefore Chymiſts uſe it in the Solution and Sublimation of Metals. And in Plants and Animals, ſince there is found both a fixt and Volatile Salt, the Volatile is frequently by the Chymiſts called *Sal Armeniac.* Concerning Salt ſee *Pliny Lib.* 31. *Nat. Hiſt. Cap.* 7. and 9. and *Dioſcorides, Lib.* 5. *Cap.* 85.

Thirdly, Nitre alſo it ſelf belongs to the family of Salts, and it is bred in a peculiar kind of the Earth, upon Walls and Rocks, where it ſprouts out like white down, and therefore 'tis cal'd *Sal-Petræ Salt-Petre*, that is Salt of the Rock. Alſo they relate that it breeds of it ſelf in *Aſia*, for it drops down in Caves and is gathered and dried afterward in the Sun. The Lydian is the beſt, which is known to be true by its lightneſs and crumbling, and color almoſt Purple. This ſort is called *Aphronitrum*, as if you would ſay, the froth of Nitre. Alſo it was bred of its own accord in *Macedonia* among the Ancients, by the Coagulation of Water, and they cal'd it *Chalaſticum*, being white and pure, and the likeſt to Salt. By Art and boiling it is extracted out of the Nitrous Earths. Now this ſame Salt is of a wonderful Nature. For to ſight it appears white; to the touch cold: yet it contains in it a Spirit exceeding Red, Hot, and extreamly apt to take flame, and perfectly of a Fiery Nature. All the ſtrength of Gun-pouder proceeds from Nitre, only Brim-ſtone makes it ſpeedily take fire: yet becauſe all the Sulphur is not inflamed as it were in a moment, but ſucceſſively and by parts; but Nitre after it hath once taken Fire ſuddenly and forcibly burns all away, (and becauſe being ſet on Fire it cannot be contained in the Room wherein it was before; and beſides the Nitre and Sulphur are as it were Enemies:) hence comes that ſame thundering force of Gun-pouder. The Chymiſts take Nitre wel purified before and purifie it yet further, by caſting into it when it is melted over the Fire divers parcels of Sulphur; and this they call *Nitrum Præparatum* and *Sal Prunellæ*, becauſe it is of rare uſe in burning Feavers, eſpecially thoſe wherein the Tongue and Throat is inflamed, which inflamation is called *Prunella*. Concerning Nitre ſee *Pliny*, in *Hiſt. Nat. Book* 31. *Chap.* 10. *Nitre or Salt Petre.* *Sal Prunellæ.*

Fourthly, Of the Family of Salts is alſo Alum, called by the Greeks *Stupteria*, becauſe of its vehement aſtringency. For all ſorts of Alum do Heat, Bind, purge putrid Ulcers, dry up moiſture, quel proud fleſh, and therefore it is uſed in many Medicaments ordained for Ulcers. It is found in its mines, and is extracted by boiling. And where Alum is bred, there commonly is found Vitriol and Sulphur. And as it is boiled it contains much fattineſs in it, which cannot be ſeparated but by mans Urin, which being poured thereon, it makes it fall to the bottom. *Dioſcorides* reckons three kinds thereof; Digd-Alum, Round Alum, Liquid Alum. There are now more kinds known. The firſt is *Alumen Rupeum* or *Rochæ*, *Rock-Alum* or *Roche-Alum*; which Greek word *Rocha* ſerves the greateſt part of Europe to ſignifie a Rock, as *Scaliger* ſaith in *Exercit.* 104. *Sect.* 6. Alſo they call it Ice-Alum becauſe 'tis congealed in the form of Ice; and Roman Alum. This is moſt uſed in ſtead of the Natural ſorts, and is made in the Roman Territory, of a certain Stone burnt. *Scaliger, in the place forecited*, ſhews all the manner of the work. Then there is *Alumen Saccharinum*, made up like a Sugar-Loaf, of Roche Alum, the whites of Egs and Roſe-water, for Women to beautifie their Skins. *Alumen Squammoſum* or *Alumen Scajolæ* (for *Scaja* and *Scalia* ſignifie a Cruſt or Scale, *Scaliger Exercit.* 104. *Sect.* 7.) 'tis made of a Scaly Stone, tranſparent like Glaſs, which being burnt divides into plates, and grows white like Plaſter. Moreover there is a ſort of Alum made of Lees of Wine, burnt in the Fire. Alſo *Alumen Catinum*, made of the Aſhes of the Plant *Kali* or *Soda*. But theſe are rather Artificial and Compound Salts of Plants, ſuch as Chymiſts do at this day make, of all ſorts of Plants. *Alum.* *Kinds of Alum.*

Plants. To the kinds of Alum is referred also *Lapis Amiantos*, *Alumen Plumosum*, Fetherd-Alum; which nevertheless is not properly Alum, nor hath it the same faculties with other sorts of Alums. It grows in Mineral Quarries, Interwoven as it were amongst the stones; being so fixt that it will bear the Fire; whence some term it *Linum Vivum*. Concering Alum see *Pliny* in *Nat. Hist. Lib.* 35. *Chap* 11.

Vitriol Fiftly, Amongst the Salts there is *Vitriol* so called from its Glassie clearness, and by the Greeks *Chalcanthon*, by the Latins *Atramentarium* Blacking, because Skins and other things were therewith died black. This kind of Salt is of an admirable, and perfectly fiery Nature, and contains in it a burning Sulphur; and therfore it performs more then other Salts, in the dissolving, colouring and generating of Metals; and the spirit thereof changes Iron into Copper. Now it contains in it two spirits, the first white, of great and known use in Physick; the other red; and in the Earth at last remains the fixed Salt. Now Vitriol is either Natural, Congealed in the Caverns of the Earth, or dropping therefrom; or else Artificial, which is boiled out of certain Vitrolous Stones, or out of a rusty kind of Earth, or out of an Ash-colour'd Earth, speckled with green and red Spots, which nevertheless makes no difference in the essence of the thing: even as Salt digd out of the Earth, and that boiled out of Salt Fountains differ not essentially. Other differences are rather to be observed, whence also the difference of virtues depends. For although all Vitriol do partake of the Nature of Brass, and therefore vitriolated Water changes Iron into Copper, which is practised in *Hungaria* and at *Goslaria*: yet some partakes more of the Nature of Brass or Copper, and other of the Nature of Iron; and therefore some is of a Blew, other of a Green Colour, and that either a deep Green or a light Green. The Blew partakes of the Nature of Copper; the Green, of Iron. And that is best which is of a deep and pleasant colour, and transparent. The Cyprian, Roman and Hungarian are commended; nor is that a base sort which is found in some parts of *Silesia*. The best now adaies is made by Chymists out of Copper, of a delicate Azure colour: which they term *Vitriolum Veneris*. There is also white Vitriol so called. Now Vitriol heats and is astringent, consumes moisture, contracts the flesh, dries, and preserves moist flesh from corruption. The Ancients also gave it inwardly, to kill Worms and to resist the Poison of Toad-stools. But now, as was said, a spirit is drawn out of it, which is more safely given, and hath a rare faculty to dry and resist Putrefaction; and therefore it is profitably used in putrid Feavers and Pestilences. See of Vitriol, *Pliny Lib.* 34. *Nat. Hist. Cap.* 12.

Chap. 3. *Of Bitumen and Sulphur.*

THe Third kind of Subterraneal Bodies or Minerals we told you were Bitumen and Sulphur in their several sorts; *viz.* All such things as are Oyly and Fat, and are therefore easily mingled with Oyl; whether they be liquid or dry. And that somwhat may be said in general touching the original of them all; 'tis commonly held, that these kind of bodies are bred in the bowels of the Earth of an Hot and Dry Exhalation. But what was said before of Earths and Salts, the same must now be said of the sorts of Bitumen and Sulphure, and afterwards of Metals; that we deny not the mixture of the Elements in these things; but seeing there is no specifick Form of any Natural Body, which had not God for its author in the first Creation of the World, we must needs hold, that these things have not begun to be after the Creation of the world, by Reason of the Various concourse, Fight, and mixture of the Elements, but that they were made by almighty God at the beginning of the World, and that they received from the same Author this mixture which they have, with their Specifick Form, and a power to multiply themselves, and to change fitting matter into themselves. Whence it is, that though there are no where wanting Elements that may be mixed; yet cannot Bitumen and Sulphur be bred in all places, any more then Salts and Metals; but there only where the Specifick Form of Bitumen and Sulphur is found; which when new Bitumen and Sulphur is ingendred, is the principal Cause and Directrix of the mixture of the Elements. And therefore though we grant that such Bodies consist of Elements: yet we deny that they have their Forms from the Elements, but here also make use

The original of Bitumen and Sulphur.

Where Bitumen and Sulphur are generated.

of

of that passage of *Scaliger* formerly cited, out of *Exercitat.* 137. *Sect.* 20. that every form of every perfectly mixt Body, as of an Adamant, though it be no Soul, is a fift Nature, far differing from the Elements.

The matter of Sulphur, and bitumen.

And although we grant that the Matter of Bitumen and Sulphur are Elements: yet are they only the remote matter: but the immediate matter and whereof all sorts of Bitumen and Sulphur do partake, is a simple similary Body apt to take flame, and Fat, and which may in general be termed Bitumen and Sulphur, as you please: where with afterwards when the Salts concure, especially that of Nitre, Waters and other things, either Spirituous or Fluid, or Dry and Earthy Metallick Concretions, (the formative principle directing all to some certain form) thence are made sundry sorts of Bitumen and Sulphur. Now Bitumen and Sulphur are bred in the Earth, or in this Globe consisting of Earth and Water. For although some such thing sometimes falls out of the Aire: yet was it first drawn up in form of an Exhalation out of the Mines into the Air, where being coagulated it falls down again. Now when it is ingendred in the Earths Caverns it is voided forth either into the Sea, and is there cast ashore; or it flows out of the Earth, either alone or with Fountain Waters, or it is digged up. And there is scarce any Region in the World, wherein some sort of Bitumen and Sulphur is not found. Now aptitude to take flame is proper to al Bitumen, and after it hath once taken flame, to burn fiercely, and if Water be sparingly poured on, not to be extinguished but to burn more furiously. The Reason whereof is, because such Bituminous substances, after they conceive flame, do not only take flame on the top, as Wood and other things, but they do totally take fire and break into flame. Whence it comes to pass, that though the outer surface be wet with Water; yet the inner part which also flames receives not the wet, but rather gathering it self into it self it grows more strong, dissipates its Enemy Water, and flames more lustily. And hence also it comes to pass, that some mixtures of Bitumen do burn under the Water it self. And the burnings of certain Mountains, Territories and Waters, do proceed from Bitumen and Sulphur. Now all Bituminous Bodies have the Faculty and Hearing and Discussing; and therefore Fountains and Baths that have Bitumen and Sulphur in them are profitably used to dissipate cold Humors, in Palsies, Epilepsies, and such like Diseases.

Bitumen is apt to take flame.

The effects of Bitumen

And there is a great variety of such Bituminous Bodies. Yet they are all reduced to two kinds, whereof one is liquid, which flows like Oyl, the other coagulated and condensated. And again there are many sorts of both. The Liquid, which go all under the Name of *Asphaltum*, are *Naphtha*, *Petroleum*, Liquid Bitumen peculiarly so called, or Native liquid Pitch.

The difference of Bitumens.

And *Naphtha* in the first place is the liquid part of Babylonian Bitumen, being Hot, Dry, and of a Nature perfectly Spirituous and Fiery; which hath so much Affinity with Fire, that the flame will leap to it at a distance, and it may easily be set on Fire by the heat of the Sun. And therefore *Plutarch* in his *Alexander*, writes, that *Naphtha* was by some called *Medeas* Medicament with which she smeared the Crown and Vail of the Daughter of Creon, and so burnt her. What if *Hercules* coming to the Altar to sacrifice, with a Garment smeared with *Naptha*, his Garment caught flame, and so he was burnt; and this was the Blood of the Centaure *Nessus*, of whom the Poets Fable? Of whom *Ovid, Metamorph. L. 9. Fab.* 3.

Naphtha.

It is question'd amongst Authors, whether *Naphtha* should be called by the Name of Bitumen, or Sulphur, or Oyl. But seeing these Names are not alwaies used in the same manner, you shal not offend, whether you cal it an Oyl, *viz.* a Native Mineral Oyl, or a most delicate Bitumen. Indeed, it is a bituminous Spirit; and it seems to be to Bitumen as spirit of Wine is to Wine, and Spirit of Turpentine to Turpentine. The most pure and excellent kind of *Naphtha* is white: yet they report that there is also found a Yellowish, and also a black sort.

The Virtues of Naphtha.

By Reason of its extream aptness to take flame, 'tis hardly used about any thing: otherwise among all the sorts of Bitumens, it is most Hot, Dry, and piercing. And therefore it may be used as an Oyntment to discuss cold Humors, also for Cholicks sleepy Diseases, Apoplexies and Palsies. Concerning *Naphtha* see *Dioscorides, Lib.* 1. *Cap.* 85. and *Matthiolus* and others that have commented upon *Dioscorides.*

Petroleum. Next to *Naphtha* is *Petroleum*, as if you would say *Petræ Oleum*, Oyl of the Rock, because it distils out of Rocks, with a very strong smel. It is a Bituminous Oyl not so subtile, nor so spirituous as *Naphtha*; and therefore it neither takes flame at a distance, nor so suddenly. 'Tis of a various colour; the best is white; the worse Yellow, Red, Black. Hitherto belongs liquid *Succinum* and Liquid-Ambar, which are nothing but certain sorts of *Petroleum*. It is found in many Regions. In *Italy*, in the Country of *Mutinum*, it drops out of the Rocks, white and Red, of a very strong smel; in *Sicily* it swims upon their fountains, and they cal it *Oleum Siculum*, and use it for Lamps instead of the Oyl, and also *Pliny* commends it for Scabby Cattle. But it is found in very many places besides; nor must we esteem it from the place, but according to its Nature. It is al of an heating drying faculty; by reason of the thinness of its Essence it penetrates and discusses excrementitious Humors, and therefore it is good against the Palsie, and cold pains and Diseases of other parts, especially the Nervous parts.

Liquid Succinum & Liquid Ambar.

Liquid Bitumen. In the Third place is liquid Bitumen, so called by translation of the general term to one special sort; it is thicker then *Petroleum*, which they mingle with Tallow, to Smear the Axletrees of Coaches and Carts. If black Pitch be mingled therewith, it serves also to Pitch Ships and is called *Pissasphaltus*. Now these three, *Naphtha*, *Petroleum*, and *Bitumen Liquidum*, seem to differ, not in original, seeing they agree for the most part in one Root, but in the thinness of their parts; so that the thinnest and most spirituous is termed *Naphtha*; the middle and Oyly sort, *Petroleum*; and the thicker and more dreggy is called *Bitumen Liquidum* in a special manner. And the difference of these Bitumens may easily be observed in the distillation of Ambar: wherein, that which is thickest and remains at the bottom resembles the Pitchy Bitumen; the Oyl resembles the *Petroleum*; and the most subtile part resembles *Naphtha*, and like it doth also snatch the flame to it self.

Maltha. Finally, Amongst the Bitumens is *Maltha*, although it seems not to be meer Bitumen, but a Liquor thereof mixt with a Clayish slime; of which *Pliny Lib.* 2. *Nat. Hist. Ch.* 104. makes mention: in *Commagenes*, saith he, a City of *Samosate*, there is a Lake which sends forth burning slime or mud, which they cal *Maltha*. If it touch any solid thing, it sticks to it: Moreover, being touched, it follows them that go from it, &c. To smear and daub Walls, it serves instead of Chalk or Lime. *Vitruvius* tels us it was used to build the Walls of Babylon. *Lib.* 1. *Cap.* 5.

Halos anthos flows of Salt, or Sperma Ceti. Also there are many kinds of Concrete and Coagulated Bitumen. The first is *Halos anthos* the Cream of the Sea or of Salt, commonly called *Sperma Ceti*; it being as it were the Froathy Fatness of the Sea. It is no part of the substance of the Sea, but a certain matter that flows in from elsewhere, which may nevertheless contract somwhat from the Sea, especially saltness. Whether *Halos anthos* and *Sperma Ceti* be one and the same thing, is here no place largly to dispute. See the Commentators upon *Dioscorides* Book the 5. Ch. 88. Only this I must advise you of, that this Name is given a Medicine, now sufficiently known, from a false opinion, that it is the Sperme slipt out of the Womb of the Shee-Whale: whereas indeed and in truth it is a fatness of the Sea; and therefore some call it, not amiss, *Ambra alba* and *Succinum Marinum*, white Ambar and Sea-Ambar. The rare efficacy of *Sperma Ceti* in dissolving Clotted Blood is known to the common people: it is also profitably given to attenuate thick Humors in the breast, and it is good for such as have the Tissick.

Its use.

Ambar Greece. Moreover among these Bitumens is *Ambra Odorata*, *Ambra Grisea*, Ambar Greece [*that is Ambar gray, or gray Amber, for Greize and Greizely signifie gray, though now obsolete.*] Now the Name of Ambar is vulgarly used for all the kinds of Succinum. In a special manner the Arabians by this Name understand a certain most Odoriferous Medicament, which the Latines call *Ambarum* and *Ambracane*. *Hermolaus Barbarus* first cal'd it *Succinum Orientale*, Eastern *Succinum*. And although the question about the Nature and Original of Ambar greece is most intricate: yet their opinion is most probable and founded upon the most Reasons, who will have it to be a kind of Bitumen. For it is a certain fat substance, most Odoriferous, found in the Sea, especially in the Indian and Æthiopian Seas, or on the Sea shores, which is the best of all other, and most pretious; somtimes harder, other whiles softer, for the

the moſt part brittle, yet ſo that under the Teeth and Nailes it may be wrought and drawn out like Maſtick. The colour ſomtimes is uniforme, and hath otherwhiles yellowiſh or white ſpecks interſperſed. And although it be found in the Sea, yet is it not bred in the Sea, but is a kind of Bitumen or Oyl flowing out of its fountains, and being on the top of the Sea expoſed to the Air it is Condenſed and Coagulated like *Succinum* or white and yellow Amber. And the Hiſtories of the Indian Voyages do teſtifie that in ſome places of *India* a moſt noble Oyl or Balſam flows out of certaine Fountains. That ſame moſt grateful and pleaſing ſmel ſprings from a moſt noble kind of Sulphur. Yea, *Crato* writes that it is Sulphur, or that there is Sulphur in Ambar Greece. It hath a rare faculty to Roborate the Animal and Vital faculties: and therefore it is good for the Brain and Heart, and makes al the ſenſes more lively. 'Tis good for old Folks, and cold Natures; it is profitable againſt ſwounding fits and Melancholly. *The Virtues of Ambar Greece.*

After Ambar Greece, follow *Succinum*, yellow Ambar, which the Greeks call *Electron*, the Arabians *Carabe*, alſo *Ambra Citrina* yellow Ambar (in way of diſtinction from the foreſaid Ambar which is called *Gryſea* or *Chryſea*) alſo *Gagates* and *Vernix*. That is now beſt known which is found on the ſhoar of *Boruſſia* by the Mediterranean Sea, in ſhape of a Maſs or Clod without any form or Figure, hard and ſolid like a Stone, ſomtimes pure and ſincere, ſomtimes mixt with Herbs, Woods, little inſects, a certain black vitriol, and other filth. Hence ſome Lumps are tranſparent and clear, ſome dark: the color is alſo various; the ſmel pleaſing in its kind. Being rubbed with a cloath it draws to it dry Chaf and Straws, by its ſpirit going forth. Being put to the flame of a Candle it takes fire, flames and ſends out much ſooty Vapor. *Succinum or yellow Ambar.*

Touching its Nature and Generation there are ſundry opinions, whiles ſome hold it to be a vegetable, others a Mineral, others partly vegetable and partly Mineral; all which here to relate, (with the Reaſons which are brought to confirm each opinion,) and to examine the ſame, would be too tedious. We ſhal propound therefore only that opinion which is moſt likely to be true: *viz.* That *Succinum* or yellow Ambar is a kind of Bitumen. For it hath all the proprieties thereof, and it is got out of Mines in the Earth, in *Germany*, *France*, *Italy*, and it hath been found on the outſide Coagulated and abſolute Ambar; and within pure *Naphtha* or *Petroleum*. Alſo that *Melanteria*, *Chalcitis*, and other Minerals did grow to Ambar. Finally, By Chymical Art an Oyl is drawn out of it, agreeing with *Petroleum*. And this Bitumen, according as it is White, Yellow, or Red, Black, Pure or Impure, ſo the like *Succinum* or Ambar is bred thereof. Now it doth not conſiſt only of Bitumen, but alſo an Aluminous, Nitrous and Vitriolated ſpirit do concur; and therefore in many places where there is *Petroleum* no *Succinum* is bred, becauſe theſe ſpirits are wanting. Now, At firſt *Succinum* or Ambar is liquid, but afterwards when it is ſhed into the Waters, without any Exhalation of parts and evaporation, it is Coagulated and grows hard by means of a Nitrous, Aluminous, and Vitriolated ſpirit, the Saltneſs of the Sea alſo, Peradventure, Concurring. And that theſe are the immediate principles of Ambar or *Succinum*, Chymical reſolution it ſelf doth ſhew. For a Vitriolated, Aluminous, Salt ſpirit comes out with the flegm: and moreover good ſtore of Salt ſticks to the Neck of the Retort. In its Rectification, if the work be diligently plied, a white ſpirit aſcends, like the *Naphtha Babylonica*, which takes flame, ſo that it is not ſafe to hold lighted Candles near the Veſſels wherein *Succinum* or yellow Ambar is diſtilled. A twofold Oyl may be drawn forth, Yellow and Red anſwering to *Petroleum*. The black Feces or Dregs, if it be ſuffered to ſtil till it is dry, do grow together into a Bitumen very like that of *Iudea*.

It Dries and Warms; it helps the diſtillations of the Head, the Falling-ſickneſs, Apoplexy, Palſie, Mother-fits; is good for ſpitting of Blood and the Conſumption, alſo for the *Gonorrhæa*, to Facilitate Child-Birth, and to provoke Urine: The Smoak thereof is an Enemy to Venemous Beaſts, and Detects ſuch as have the Falling-ſickneſs. *The Virtues of yellow ambar.*

Of kin to *Succinum* is *Gagates* or Jet, ſo that ſome take it to be the ſame. It is alſo a kind of Bitumen, or a Bituminous ſtone, for the moſt part black; yet ſomtime of a pale or yellow colour. 'Tis ſoon ſet on Fire, ſmels like Bitumen. It *Jet.*

detects such as have the Falling-sickness, by the Smoak thereof; and hath a softening and discussing faculty.

Asphaltus. There is yet another kind of Bitumen, but more concrete, which is called by the general Name *Asphaltus*. It is an hard kind of *Asphaltus* or Bitumen, and hath no filth mixt with it. It is of a solid substance, and shines like purple when it is broken. It is weighty and of a strong smel. Of this kind, that of *Sodom* is the best. That which is more impure doth not shine so, nor hath so strong a smel. It Dries and Heats, Discusses, Mollifies, and sodders Ulcers: it takes away fits of the Mother in a Suffumigation. See *Dioscorides* in his 1 *Book*, *Chap.* 83. *&c.* and the Commentaries of *Matthiolus* and others.

Finally, To the Family of Bitumens are to be referred certain Bituminous Earths and Stones. For it matters not much whether you cal them Earths or stones. Their first and chief Original is from Bitumen, with which as there is more or less of an Earthy and Stony matter conjoyned, so it receives this or that Name. And hence it is that in the Nature of Bitumens we meet with great difficulty, whiles Writers regarding the places where they are bred, or the outward Figure, but little considering the internal Nature, either they separate things of the same kind, or confound and Joyn together things of different kinds.

For this Bitumen of which such kinds of Earths and Stones do consist, is not sincere and pure Bitumen, but mixt with Earthy Juyces, Mud, Potters Clay, Veins of Metal and Stones. Of this kind is *Terra Ampelitis* so called, which is black like Sea-Coals, and resembling Bitumen; it dissolves in Oyl, resists worms, and Dries and softens as *Asphaltus* doth. Some account this *Ampelitis* Earth and Pit-Coals to be all one, but others make a difference. If they are not just one and the same, at least they are much of kin; whence come the sundry Names of the Germans which they give these kind of Bodies, as *Schwartze*, *Kreide*, *Koblerde*, *Steinkehlen*, *Bergkolen*, *Dorff*, *and Durpte*. For these kinds whether of Stones or Earths, have all one Root and Mother, *viz.* Black Bitumen: the Particular difference proceeds from the Various manner of Concretion and Admixture of other things.

Terra Ampelitis.

For that which the Germans cal *Dorff*, and *Durpte*, Peat and Turfe, are Bituminous Earths which they Cut and Dry for Fewel. It is digged in *West-Frise-Land*, *Gelderland*, *Flanders*, *Brabant*, *Zeland*. It is also found in *Collao* a Province of *Peru*, which *Monardus* describes in these words. In *Collao* a Province of *Peru* there is a place quite bare, without Tree or Grass, because the Earth is Bituminous, out of which the Indians draw a liquor, good to cure very many Diseases. The manner of their drawing of the said liquor is thus. They cut the Earth into Turfs, which they lay in order upon poles or thick Reeds in a Sunny place, having vessels under them to receive the Liquor. For by the Heat of the Sun this Bitumen Melts, or the Juyce included in the Earth dissolves and sweats through. Afterward the Turfs remain Dry, and Robd of their Oyly Liquor, and so become fit for Fuel. But the Fire made of them is hurtful, by Reason of the thick blackness of the Smoak, and the stinking smel it makes. Yet for want of other Fuel they use the foresaid turfs. The Liquor which fals from them is good for many Diseases, especially such as proceed from cold. For it Mitigates pains, and discusses cold swellings. Wounds are cured therewith, and other Diseases for which *Caranna* and *Tacamahaca* are good. Its color is dark Red inclining to black, and its smel is strong. In *Saxony*, *Misnia*, *Low-Germany*, *Scotland*, and other places, Bituminous and Fat Turfs are found: the Germans cal them *Motten*.

Sea-Cole or Pit-Cole. Lithanthrax, *Carbo Mineralis*, or *Fossilis*, or *Carbo Lapideus*, Stone-Coal, Mineral-Coal Pit-Coal or Sea-Coal, is harder and of a stoney Nature, consisting of Bitumen and a stone making Earthy Juyce, Black, good to make Fires, especially for Smiths Forges. 'Tis found in *Germany*, *Bohemia*, *Scotland*, in many places.

And some hath in it more Bitumen, and some more of the Stone making Juyce: and therefore some of it will easily burne, but some wil not burn, unless it be mixed with other Coals and blown with bellows.

But he that would know more concerning Bitumens, let him read the Commentaries upon *Dioscorides*, especially that rare third part of *Andræas Libavius*, wherein largely and learnedly he explains the History and Nature of all sorts of Bitumen.

In

In the next Place comes Sulphur, or Brimstone, which the Greeks call *Theion*; it is a Mineral Juyce, consisting of one part which is inflamable and sends forth a grievous smel, and of another part which is Earthy, thick, and fixed, having a vitriolated Juyce mingled therewith. It is reputed the Agent and Father in the Generation of Metals, and Coagulates the Mercury; if there be conjoyned a Metalline Spirit, and a Seminary Principle. Of which if it be destitute it destroies Metals, and consumes such things as are volatile. Now it is twofold, Native or Quick, *Apuron*, which hath not felt the Fire. For it is engendred pure solid and in clods, so that there needs no Fire to separate its Impurities. The Ancients describe it to be transparent. And now adaies there is hardly any such found; but it is of an Ashy color, and when it is broken, Yellowish within. Factitious or Artificial Brimstone is boyled out of the Sulphurous mine which is digged out of the Ground. Now there is some difference in the Artificial, especially in regard of Purity and colour depending thereupon, and some is yellowish, other some paler, and some enclining to an Ash-color. *Brim-stone*

Of Sulphur and Quick-silver is made *Cinabrium Factitium*, Artificial Sinoper. Of the Smoak of inflamed Sulphur received in a Glass Bell is made a sharpe Liquor, like Spirit of Vitriol. And flower of Brim-stone is the purer part thereof, being sublimated with Salt and Calcined Vitriol.

Now Brim-stone is of a digesting, discussing and drawing faculty, it is good for such as breath short and have an *Empyema*, taken in an Egg. Externally applied with Butter and Hogs-Greece, it Cures the Itch; and with Turpentine it heals the Tetter. *The Virtues of Brim-stone*

Neighbor to Brim-stone is Arsenick, Orpment, and Sandarach, which seem to agree in Nature and Faculties, and only to differ, because the one is more the other less digested in the Bowels of the Earth; or that one hath more or less Quick-silver and Salt mingled with the Sulphur. Some take Arsenick for the kind, and call Orpment Saffron-colour'd Arsenick; Sandarach, red Arsenick; Risagal, white Arsenick. But that which they cal white Arsenick, is now adaies known by the Name of Arsenick absolutely: *viz.* Orpment so often sublimed with Salt til it become white, and Transparent like Chrystal: the strongest of all Eating and Fretting Putrifying Poysons. Now Orpment is a Sulphureous Mineral Juyce, having joyned therewith a little Quick-Silver, and the Spirit of Salt. Al the kinds are caustick and corrosive, and Enemies of the inward parts, which they fret, and consume the radical moisture. Yea, it is not safe to apply Arsenick externally by Reason of its extream Venemous and Corrosive Nature. But if it be Calcined with Nitre, its volatile mercury and inflamable Sulphur are taken away, and a certain buttery Fatness remains, which is used externally for Fistula's and Ulcers hard to cure. *Arsenick, Orpment and Sandarach.*

Hither also we must refer Antimony, *Stimmi* or *Stibium*, which although it seems to come nearer the Nature of Metals, yet is it a Mineral Body, resembling Lead, but brittle, consisting of Sulphur, crude Arsenick and much Quick-silver of an Earthy Nature, but all of them volatile. And therefore it yields a stinking and hurtful Fume, which for the most part is Mercurial, but in some part Sulphureous and Arsenecal. Being crude applied externally it imitates the Virtues of Lead, and is binding, hinders the growing of flesh, takes away the filth of the Eyes, and cures Ulcers. It makes great work for the Chymists, who make thereof sundry purging and sweating Medicaments; of which they have written whole Books, wherewith you may consult. *Antimony.*

Finally, Betwixt Antimony and Lead is *Bismuthum*, which is therefore called Ash-colour'd Lead; being a Mineral Body whitish and Livid, Hard, Brittle, consisting of Earthy and crude Mercury, Sulphur and Arsenick, and all of them impure and Volatile. *Bismuthum.*

And that we may conclude this subject, those various kinds of Earths and Minerals which we have mustered hitherto, (and if there be any other to be reckoned,) they have their original from the Roots of Minerals. For in these also there happen sundry corruptions. For although Gold and other Metals now perfectly digested do not putrifie, and seem incorruptible; yet in their first Original they may be corrupted. So *Terra Sigillata*, of which we spake before, is thought to be nothing else but the first matter of Gold, Silver, or some other Metal (for there are sundry kinds thereof)

thereof) corrupted, *viz.* When the principles of Metals do not remain united, but the Sulphur and Mercury are Separated and Sublimated, and either transferred into some other place, or dispersed into the Air. So Antimony seems to be nothing else but crude or raw Gold, corrupted before it was ripe; and *Bismuthum*, immature Silver corrupted.

Chap. 4. *Of Stones and Jewels.*

THe hardest of Minerals are Stones. And since that under this kind are comprehended both common Stones and Precious Stones or Jewels, we must first speak somthing in General of the Generation of Stones. It is commonly held, that by the concourse and mixture of Elements, the first and Second qualities Co-operating, Stones and precious Stones are produced. And though it is not to be denied, but that the Elements do concur unto their Constitution: yet the Elements alone do not suffice, and are only the remote cause of Stones and Jewels. Be the Elements mixed how they can, yet the Primary agent being absent, no precious Stone is made of them.

The Generation of

They who would produce a nearer Cause, have made exhalations the matter of Stones: but that also is too remote, nor wil it suffice alone, unless it be more specially determined. *Avicenna* therefore and *Albertus Magnus*, that they might come more near to the business, have held the matter of Stones to be Clay and Juyce, *viz.* A clammy roaping Clay, to the mixture whereof more Earth hath concurd then Water: and a Juyce that been hath suckt in, and raked off from the Earth, or that hath a Tincture of some Metal. This opinion others follow, and hold that Stones are made of Clay or Earth glewed together with a clammy moisture, such as are dark; and with a Transparent Liquor such as are clear and Transparent.

Yet in truth, not only Water and Earth, but all the Elements are in Stones, especially precious ones. Yea, and the Chymists think the Elements are not sufficient, but that as Metals so Stones and Jewels they say are made of those three principles, Mercury, Sulphur and Salt. Of which opinion I shall speak elsewhere.

This only we shal hint in this place; that the matter of Metals, Stones and Jewels, is very near of kin, which not only the place where they grow but many other things do witness. For examples sake, let us take Pome Garnets, out of which and Iron Tinctures are drawn so like, that it is not easie to discerne one of them from another; and a more base sort which are found in *Silesia* and *Misnia* do resemble Iron also in color. Also many Stones, if they are burnt, do send forth Sulphureous fumes, just as Minerals and Metals do; and of Metals Glasses are made which do very much resemble some precious Stones. And therefore Jewels and Metals seem not unfitly to be reduced to common principles: and it seems possible to reduce Jewels to some certain Metals.

The efficient Cause.

Authors do stick yet more in Explaining the Efficient Cause of Stones: and the most have recourse herein to Heat and Cold, and favour nothing beyond the Elementary qualities. And among Stones, those which they count to be made of Clay, they think are coagulated by being baked together by Heat and dryness: and such as they conceive to consist of a watry matter, they hold to be Coagulated and hardned by vehement cold, as Crystal. But many such dark Stones are generated in the midst of Waters and springs, whose Coagulation cannot be made by the baking of heat and dryness. And they are truly too simple, who think that Crystals, Adamants and such like Stones, are frozen together by the Cold; since they are generated in the hottest Countries on the Surface of the Earth, both Adamants and other transparent Jewels; nor will they melt with Fire.

The true Cause of Concretion and Coagulation.

The Chymists hold Salt to be the Cause of Concretion and Coagulation: against which opinion of theirs although some fiercely dispute, yet is it not absolutely to be rejected; seeing many evident Documents do prove the same; and certain it is, that many things are Coagulated and grow together in moist subjects, where neither dryness, Heat, nor cold have place. Yet, seeing there are two sorts of Concretion, which happen without adding or taking away any part of the matter: they

A double Concretion

are

are in no wise to be confounded, and we must speak distinctly of the distinct manners of Coagulation.

The Concretion of Salts:

The former manner of Concretion is seen in Salts, as in common Salt, Vitriol, Nitre, Alum, Urin, and in the Salts made out of Plants and Animals may be seen; and it is proper to Salts, which naturally tend to such a Coagulation, and indeed under a certain Figure; as the said diversity is to be seen in Nitre, Vitriol, Alum and other things.

The cause of solidity and hardness:

But because Salts have not hardness of themselves, but are easily broken and dissolve in moisture, but Jewels and Stones do not only grow together, but they are solid and hard. and do not melt in moisture: this kind of Concretion or growing together is different from the former. The cause of which concretion some do also refer to Salt, and the hardness to the admixture of Earth therewith: But others again (& that probably enough) do hold that this Stoney hard concretion or growing together of Bodies doth proceed from a Stone making spirit or Juyce, which Stone making spirit and Juyce is every where found in the Earth and in the water, but not without Salt.

The Immediate Cause of Stones and precious Stones

And thus the immediate cause of Stones and Jewels is agreed to be a Stone making Juyce, that is to say, a matter of its own Nature tending to such an hardness and solidity. Now that several Stones and Jewels are generated, proceeds from the especial form of each. For every precious Stone hath its proper and specifick form whereby it is differenced from al other, which it obtains from, (as I may say) its Seminal principle of Generation. Which doth not proceed from the Mixture of the Elements, but, as *Scaliger* rightly Names it, it is a fitt essence, put into this sort of Natural things by almighty God, at the first Creation of the world. Which seminal principle and *Architectonick* Spirit, although it doth not appear in a Body peculiarly distinct, as in most plants, nor can its Essence be sufficiently explained, yet must it not be therefore denied. For as the Willow, though it produce no Seed as other Plants do, yet it hath a Seminal principle dispersed through the whole tree, and so is propagated by a bough cut off and stuck in the ground: so the Seminal principle of Jewels and Stones lies concealed in the Stone making matter; and in this darkness of our Minds its essence is unknown to us, as al other forms are; and their difference is not known save by the diversity of their faculties, operations and Qualities. For upon this diversity of Forms, fit matter being Joyned thereto, depends the diversity of colours and external shapes.

Hence the Crystal and *Adamant* of *Hungaria* and *Silesia* have an Hexagonal or Six-corner'd shape; the Occidental Smaragds are four Square; the Bohemian Granate and the Stone *Geodes* have a Globous Figure; and other precious Stones have other shapes.

Whence the Colour of precious Stones is:

Now I conceive the Colours of precious Stones may chiefly be drawn from the Sulphur of Metals. For, Carbuncles, Rubies and Granats, do participate in their Tincture with Gold and Iron: The Turkois hath the Tincture of Copper. And there may by Spirit of Salt, Urine, and other liquors, Tinctures be drawn out of Metals, which do perfectly resemble the Colours of certain precious Stones. And from the same causes, *viz.* The forms and Mineral principles, other qualities also of Stones and Jewels, as hardness and weight. &c. As also their Virtues and properties do flow.

The Natural place of precious Stones:

As to their Native place, Stones are found every where; precious Stones, as in many other Countries, so in *Misnia*, *Silesia*, *Bohemia*, and other places of *Germany*. But the more noble precious Stones are chiefly found in the *Indies*. The cause whereof is diversly by divers assigned; and the most refer the same to the posture of the Sun and Stars over the Zenith. Yet since in *Africa*, *America*, and other Regions which are under the same climate, there is no such store nor such excellent precious Stones found: the cause is rather to be attributed to the Nature and disposition of the Soil, and the Seminal principle implanted therein at the Creation.

The difference of Stones:

Now Stones are some vulgar, others precious, according to the Purity or Impurity of the matter whereof they consist, and the nobility of the Form. For vulgar Stones consist of a gross and impure matter, and have a more Ignoble Form: and therefore their effects are less excellent. But precious Stones consist of a more pure and Subtile matter, and have a more noble form. For the Chalk-stone, and other

commo

common Stones have alſo their ſulphur, which is ſufficiently diſcovered when they are burnt; but much thicker and impurer then the Granate or Amethyſt.

Ground Unicorne Now Stones are ſome Spungy, others Solid. Amongſt thoſe kinds of Stones that is juſtly in the firſt place to be explained which is vulgarly taken for Unicorns Horne; and ſome cal it ground Ivory, others ground Horn. For in *Thuringia*, as alſo in *Bohemia* and other places, ſuch Horns are found; yea, and not only horns but other bones alſo; which are ſaid to be good to Sodder wounds and to heal Ulcers. *Its Uſe* But eſpecially, experience hath taught that theſe Stones have no ſmal uſe in the Falling-ſickneſs, Malignant Feavers, the Peſtilence, gripings of the Belly in Infants, and the Cure of other Diſeaſes; and therefore they are commonly given out for Unicorns Horns. Howbeit they may eaſily be diſcerned from the true Unicorns Horn. *How it may be known from true Unicorns Horne:* For the true Unicorns Horn is hard and ſolid, that it can hardly be raſped, much leſs can it be beaten to pouder: nor doth it much cleave to the Tongue; But this Stone is not hard, but as it were calcined, it is eaſily broken and rub'd to pouder, and being put to the Tongue it ſticks faſt, like *Terra Sigillata* or Bole-Armeniack.

Touching the Generation thereof, Men are of ſeveral opinions. Some conceive they are the bones of an Unicorn overwhelmed in the Earth by a flood, or ſome other occaſion, which remain after the fleſh and ſofter parts have been conſumed by Time. But this opinion is not agreeable to reaſon. For how ſhould there be ſo great a number of Unicorns, in *Thuringia*, the Hercinian Foreſt, near *Elbingroda*, alſo about *Heidelberge*, *Hildeſheme*, in *Miſnia*, *Sileſia*, *Moravia*, and in many other places? And why are theſe horns found in thoſe places rather then elſewhere, where it is more likely that there are Unicorns? Moreover ſtones are found, which repreſent the Bones not of this Creature only, but of others alſo.

Its immediate matter: More probable therefore it is, that theſe are Mineral Stones. But what is their immediate matter is not eaſie to tell. Some hold that it is Bitumen or corrupted Ambar; others, as *Anſelmus Boetius*, *Lib.* 2. *Cap.* 242. that it is *Marga*, or a kind of Marle; others that it is ſome putrified and rotten Stone. This is certain, that it is a mineral matter, not unlike ſome *Terra Sigillata*, or a Mineral Juyce mingled with ſome ſuch Earth, and ſhaped into the Form of an Horn, Tooth, or other bone.

Nor let that ſame external form ſtumble any man. For though no man can eaſily tel the Cauſe of its Conformation, though many have labored to do it; yet certain it is, that many wonderful things are ſhaped in the Earth. Not to ſpeak of other things at this time, 'tis ſufficiently known, how many ſundry ſhapes are ſeen in Stones digged up at *Iſlebia* and elſewhere. For there are ſeen in thoſe Stones ſundry ſhapes of Animals and Plants; of a Frog, a *Salamander*, a Serpent, a Viper, an Eel, a Carp, a *Gilthead*, a Gudgeon; Yea, and the Pictures of Princes and renowned Men. And what ſhould be the cauſe of theſe Pictures 'tis hard for any man to tel.

As to the Virtues of theſe Stones, 'tis certain they are very good againſt the Falling-ſickneſs, and Malignant Diſeaſes, and therefore they are many times uſed no leſs ſucceſfully then the Horn which is counted to be the Unicorns.

Spungy ſtones: Now vulgar Stones are either Porous or Solid. The Porous or Spungy Stones, are the *Tophus* or crumbling gritty Stone, the *Pumice*, the *Oſſifragus*, the *Oſteocolla*, *Stalactites*, and moſt of thoſe Stones which are bred in living Creatures.

Solid ſtones: The ſolid Stones are many, the Sand-ſtone, the Chalk-ſtone, the Flint, the Fire-ſtone, the Whet-ſtone, the Touch-ſtone, the Smiris wherewith they cut Glaſs. Sundry kinds of Marble, Alabaſter, Serpent-ſtone, Porphyry-Stone, Free-ſtone, *Ceraunias* or Thunder-ſtone, the *Belemnites*, ſo called; and very many more.

Alſo there are other Stones of a middle Nature betwixt thoſe common groſs Stones and the Noble precious Stones: I ſhall only ſpeak a little of one or two of them.

The

The Load-ſtone in the firſt place, is a ſtone ſufficiently known; and its effects are wholly wonderful, the cauſe whereof many learned men have hitherto labored to render. Now the effects of the Load-ſtone are either of the Stone alone, or of Iron toucht with the Stone; or of both the Stone and Iron. The ſimple effects of the Stone are, to draw Iron to it, and to turn towards the Poles of the world. That it drew Iron was a thing not unknown to moſt of the Ancients; but its faculty of turning to the Poles of the world, as it is at this day very well known, ſo was it not known to the Ancients; nor hath any man been able as yet to make it appear, that it was known to *Ariſtotle, Dioſcorides, Theophraſtus, Lucretius, Pliny*, or any of the Ancients: but this Virtue was firſt diſcovered ſome few Ages ſince; although it is uncertain who was the Author or Inventor. *The Load-ſtone and its wonderful effects.*

But what is the Cauſe of this motion, and whether it ſhould be ſought in Heaven or in Earth, is very obſcure. But that we may ſearch it out as much as is poſſible, we muſt preſuppoſe this in the firſt place, that the Load-ſtone in many places doth not turn exactly to the Poles of the world but towards them, declining a little from them, in ſome places more, in others leſs. Which declination from the Poles of the world is altogether of great uſe and moment. For whereas the Ancients at Sea knew only in the day time by the Sun in what Meridian of the world they ſailed; and in the night they knew by the Stars the Elevation of the Pole, and in what Latitude of the World they were: now by the help of the Load-ſtone they can find in what Longitude they are: and ſeeing it is confeſſed by all the Ancient Geographers, that nothing is more difficult in al Geography then to find out the Longitude of places, for which cauſe they do ſo much vary in aſſigning the Longitude of the moſt Famous Cities: by help of the Load-ſtone alone the Longitude of every place may moſt eaſily and exactly be found out. The Ancients indeed reckon'd their degrees of Longitude from the fortunate Iſles, and there they made the beginning and end of the Globe of the Earth. But the late Coſmographers obſerving that the Pole of the Load-ſtone and the Pole of the world did conſiſt in one Meridian, in the tenth degree beyond the fortunate Iſles Weſt-ward, about the *Azores* or Flandrick Iſlands; they make the beginning of Longitude there, not only to pleaſe themſelves, but moved thereto by this Natural reaſon Namely becauſe in that Meridian the Poles of the Load-ſtone and the Poles of the world do agree together. Now from that Beginning and Meridian, towards the Eaſt, the Declination encreaſes more and more, and it is greater or leſſer, according as the place is nearer to, or further from this firſt Meridian. In *Germany*, eſpecially about *Norinberge*, the Declination is ten degrees; here at *Wittenberge* about nine. The Hollanders who have ſailed into *Norwey* and the neighbouring places towards the Eaſt, have found the declination of the Load-ſtone from the Meridian to be ſixteen degrees; and at *Nova Zembla* ſeventeen degrees in the more Eaſterly parts, provided they made their obſervations with exact Inſtruments. And it is probably aſſerted, that if the Hollanders ſhould finiſh their Navigation towards the Eaſt, the more Eaſterly they went and the nearer to *China*, they ſhould find the declination of the Load-ſtone from the Meridian ſo much the more abated, and they ſhould at laſt come to that place towards the Eaſt, in which the Poles of the Load-ſtone and the world would be in one Meridian, and that there would be no deflection of the Pole of the Load-ſtone in the hundred and eighty degree of Longitude, oppoſite to the beginning of Longitude in the Weſt.

Yet there is a certain learned Man who holds that the Hollanders are deceived in this point. For when they looktupon their compaſſes they did not conſider that the Compaſſes were ſo made, that the Iron toucht by the Load-ſtone was not placed juſt under the Flower-de-luce painted upon the card, but was diſtant therefrom certain degrees. And therefore whiles the Hollanders lookt upon the Flower-de-luce, and ſaw that it pointed directly towards the North, they conceited that there was no Magnetical declination in that place; whereas the Iron toucht with the Load-ſtone was ſome degrees diſtant from the Flower-de-luce or the true North-point. Aud therefore he placed the firſt Meridian, with the Ancients, in the fortunate or *Canary* Iſlands, becauſe in that place there was no declination of the Load-ſtone at all. In which point experience muſt be judg. Yet it ſeems to me improbable, that the Hollanders who knew very wel how to make their compaſſes, ſhould be ſo heedleſs in ſuch a Caſe.

But be it how it wil be, this is certain and confirmed by manyfold experience, that the Pole of the Load-ſtone is diſtant from the Poles of the world twenty three degrees or thereabouts.

And hence ſome do probably collect, that the declination of the Poles of the Load-ſtone from the Poles of the world, and the declination of the Poles of the world from the Poles of the Zodiack, is one and the ſame; and ſince the utmoſt declination of the Planets is twenty three degrees and ſome minutes, that doubtleſs therefore the declination of the Poles of the Load-ſtone from the Poles of the world is the ſame.

The Cauſe of the Loadſtones turning to the Pole.

But doubtful it is whether the Cauſe of this motion of the Load-ſtone towards the Pole is in the Heaven or in the Earth, and where in the Heaven, or in the Earth. Some are indeed of opinion that there are certain Mountains of Load-ſtone under the Pole, to which the Load-ſtone moves by ſimilitude of Nature. But they cannot wel rel what or how great thoſe Mountains are; nor are mines of Load-ſtone wanting in other parts of the world, but they are found in many Regions, eſpecially in *Egypt*.

Others ſay the Load-ſtone turnes to the Pole-Star, others that it turnes to ſome Stars about the Pole-Star. But the Load-Stone doth not look directly to the Pole; ſave in ſuch places where the Meridian goes through the Pole of the World and the Pole of the Load-ſtone both at once: in al other places it declines.

Moreover, that which is ſaid of the converſion of the Load-ſtone to the North pole, is now adaies called in queſtion by learned Men. And ſome do make two oppoſite points in the Load-ſtone, whereof one turnes to the North, the other to the South, if the Stone hang moveable and free. Which though others do not wholly deny; yet they ſay that point is ſtronger which turns to the South then that which turns to the North, and ſo they hold that the Load-Stone turns rather to the South then to the North. And though there were nothing in the Load-Stone which did Naturally turn to the North; yet its turning to the South is ſufficient to ſhew the North-Pole. For ſince the South-Pole is juſt oppoſite to the North, if one part of the Load-Stone or of the card touched with the Load-ſtone turne to the South, the other end muſt of neceſſity point to the North. Of which this is a remarkable token, that thoſe who make compaſſes and Sun-Dials with magnetick Needles, do rub the Load ſtone upon that end which ſtands to the South, and not upon the Croſſend which Looks to the North; and therefore the Magnetick Needle turns primarily to the South, and the oppoſite part points to and ſhews the North.

Hence therefore ſome have come to be of opinion, that the Load-ſtone is turned towards the South; becauſe all the Planets have their Efficacy and Operation in the South. Since they move from the Eaſt, through the South, towards the Weſt. Yet in very deed, although it go ſo in our Regions: yet there are oppoſite places, wherein the Ecliptick declines from the Æquator towards the North, and the Planets perform their courſes, from the Eaſt, through the North, towards the Weſt. Moreover the Planets do not abide in the ſame place, but one in one place, another in another; moreover they do not ſtick faſt, but paſs over the whole Heaven every day. If therefore the Load-ſtone ſhould look towards the Planets, it could not look towards one place, ſince there are divers Planets; nor would it ſtand ſtill, but ſhould be alwaies moved, following the motion of the Planets.

The opinion of others is more probable who hold, that as other things tend to their own proper place: ſo the Load-ſtone unleſs it be hindred doth alſo deſire alwaies the ſame Scituation which it had in its Native place. Wherein nevertheleſs we muſt conſult with experience, and enquire how the Load ſtone is Scituate in the Mines.

But that Opinion is moſt probable, that the Load-ſtone is moved towards its own Pole in the Earth, which is diſtant about twenty three degrees from that point which anſwers to the Pole of the World: and that either the South only, or if the Load-ſtone have two Poles, and one part thereof turns to the North, another to the South (concerning which we muſt again conſult with experience) yet that it chiefly tends to the South: and that it hath ſome affinity with its own place, or with the things that are there; and that doubtleſs the point to which the Load-

ſtone

ſtone moves muſt be held to be rather in Earth then in Heaven. For that ſame point is fixed; but the Pole of the Zodiack, or any other Star thereabouts to which the Load-ſtone ſhould be moved, doth it ſelf move and finiſhes its round in the ſpace of twenty four hours; whereas the Load-ſtone doth perpetually turn to one point. Nor can it be perceived that the Load-ſtone, or the ſmalleſt Iron Wires toucht with the Load-ſtone do ever move upwards towards Heaven. Contrariwiſe, good Authors relate that the Load-ſtone tends towards the Earth, which may be proved, they ſay, by theſe experiments. If you place a Needle in *Æquilibrio* ſo ſo that both ends are equally diſtant from the Earth, and then touch one end with a Load-ſtone; they ſay that end will bow towards the Earth more then the other. Alſo if you weigh pieces of Iron Wire, and after they are toucht with a Load-ſtone put them in the Scales again, you ſhall find that they weigh more then they did before they were touched, becauſe they encline towards the Earth. And therefore, ſince two Poles of the Load-ſtone are to be conſtituted in the Earth, one diſtant about twenty three degrees from the point juſt under the North-Pole of the world, towards the place now called the ſtraits of *Anian*, the other in the South part oppoſite, Scituate in the Meridian which paſſes through the *Azores* or Flandrick Iſlands, *Caput Viride* and *Caput Corvo*, or (as others will have it) which paſſes through the *Canary* Iſlands: in all places under this Meridian there is no declination of the Load-ſtone, but the Needle touched by the Load-ſtone falls exactly with the Meridian; in all other places of the whole Earth the ſaid Needle declines from the Meridian of the place, ſomtimes more, ſomtimes leſs, ſomtimes towards the Eaſt, otherwhile towards the Weſt; whereof ſee the obſervations of the Hollanders, and the Mathematical Memorials of *Simon Stevinus*, in the 5 Book of his *Geography*. But what that is to which the Load-ſtone is moved, is hard for any man to tel: let that ſuffice us, which *Scaliger* writes in his 131. *Exercitation*, where there are alſo other things concerning the Load ſtone, worthy to be read: *Nature* (ſaith he) *being linkt in a league of Amity to it ſelf, hath allied all things as well thoſe above as theſe here below in a perpetual band of friendſhip, which makes all this world to be one thing admirably diſpoſed; ſo that there are not only certain degrees as it were of approach and diſtance in things ſeparated: but alſo the Commixtures of thoſe ſubſtances, which are quite parted one from another.*

Now concerning the Virtue of drawing Iron (for I do not here diſpute, as *Scaliger* hath it in *Exercit.* 102. *Sect.* 6. whether the Load-ſtone draws Iron, or Iron the Load-ſtone; for which ſo ever it is, the Cauſe is one and the ſame) the Controverſie is no leſs. *Epicurus* is ſaid to have held, that from the Iron and Load-ſtone *Atomes* do flow, which agreeing in Figure do imbrace one another, and ſtrike againſt the Bodies of the Load-ſtone and the Iron, from whence being reflected they draw the Iron. *Anaxagoras* held that the Load-Stone had a Soul and therewith drew the Iron. From whom *Cardan* differs not much, who alſo avers that the Magnet or Load-ſtone doth live; whom *Scaliger* oppoſeth *Exercitat.* 102. *Sect.* 5. *Marſilius Ficinus* in *Lib.* 3. *de Vit. Cœlit. Compar. Cap.* 15. fetches the Cauſe hereof from the Conſtellation of the Bear, to which both the Load-ſtone and Iron are ſubject, and both do orderly follow the Bear; but the Load-ſtone holds the upper degree in the propriety of the Bear, and Iron the lower; and that ſo the Load-ſtone as being in the upper order draws the Iron, which he reckons to be in the lower. *why the Load ſtone draws Iron*

But in good earneſt, if we ſhal diligently weigh the matter, we ſhal hardly find any thing more probable then that ſame mutual conſent of things Natural. For therein well-near al learned men that have pondered the Nature of the Load-ſtone do conſent, that the Load-ſtone is a kind of Iron Mine, and that Iron may be made thereof.

And here is to be obſerved, that the whol body of that which we cal the Load-ſtone, is not indeed the Load-ſtone, for the whole Stone doth not draw Iron; but that the ſubſtance of the Magnet is diſperſed in its ſtone like Veins; even as other Metals are ſeldom bred alone and pure, but in their Matrixes or Wombs, and therfore the Magnetick-ſtone draws the Iron only with that part, where is the Vein of the Load-ſtone.

From whence this alſo follows, that the Cauſe of Attraction is rather in the Load-ſtone then in the Iron. For the Iron is already a fixed metal: but the Load-ſtone is not yet fixed, and therefore it can more freely ſend forth its ſtrength and ſpirit.

Andreas Libavius, *Part.* 3. *Singul. Lib.* 1. *Chap.* 12. where he treates of the attractive Virtue of the Load-ſtone, endeavours to aſſign yet a more ſpecial Cauſe, and writes that the Nature of this principle in the Load-ſtone is Bituminous, which is reduced and directed to a ſingularity with the Iron, by ſimilitude of that conſpiracy and mixture, whereby the ſame principles have grown together in Iron: and that an Iron and Bituminous ſpirit is common to them both, but that it doth not flow ſo ſtrongly nor ſo continually from the Iron as from the Load-ſtone, becauſe of the different Coagulation or Conſiſtency. Where we willingly grant that a certain Sulphur or Sulphurous ſpirit is common to the Load-ſtone and the Iron: which if *Libavius* pleaſe to cal Bitumen (for he counts Bitumen to be a thing more general then Sulphur, and that Sulphur hath its original from Bitumen) I will not contend with him about the Name; but that Bituminous or Sulphureous things only have a mutual Appetite one to another, I ſee not how he can prove. Nor doth he tel us, whether they mutually deſire one another, by Reaſon of their Sulphur, or of their whole eſſence. But whatever is the Cauſe of the affinity betwixt the Load-ſtone and the Iron, which cannot be denied; that general Rule there laid down by *Libavius* holds true: one Nature covets another of the ſame ſort, and like will to like, as much as it can; eſpecially there where the Virtue ariſes and ſticks, and apprehends another like it ſelf.

The Load-ſtone armed.

We muſt not in this place paſs over the armed Load-ſtone, whoſe force is much ſtronger then that of the unarmed. For a Load-ſtone unarmed will draw only a Pack-needle or a bit of Iron hardly weighing a dram or two: but if it be armed, it draws ſixteen ounces or more. The Art of arming them, is this. Seek out in a Lump of a Load-ſtone its Poles, which may be done with the help of a Needle in a Sun-Diall; the Poles being found, let the Load-ſtone be poliſhed, and reduced into ſuch a ſhape as it is capable of (howbeit the long ſquar is the moſt convenient ſhape) yet ſo that the Axis reaching from the one to the other Pole may lie in the middeſt betwixt two parallel lines, equally diſtant from each of them. The ſides be ng formed, let alſo the upper and lower part be wrought and poliſhed, as alſo the ſides, to the ends of the Axletree. Then let two plates be framed of the beſt Steel, of which the one ſide which touches the Load-ſtone muſt be ſmooth and even, if the ſides where the Poles are be plain; or of what ſhape ſoever they be, they muſt be ſo fitted to the ſides of the Load-ſtone that no ſpace may be left betwixt the Steel and the Load-ſtone, but the other ſide muſt be a little round, and on the lower ſide the plates muſt hang a little beneath the Load-ſtone; and the parts that hang under muſt be ſomwhat thicker and ſquarer then the reſt like Pillars. The Plates being thus formed muſt be applied to the Poles on each ſide, and to keep them faſt they muſt be bound with two round hoops of Silver or braſs, which muſt go about the Load-ſtone above and beneath. Alſo let the upper ſide thereof be covered with a Plate of Silver or Braſs, with a Ring whereby to hang up the Load-ſtone thus armed. When it is hung up apply unto the little Pillars of Steel which come beneath the Stone a Plate of Steel as big as it can draw and there let it hang.

Bezoar Stone.

In the next place we muſt not forget Bezoar Stone, whereof Many things are extant in the writings of Phyſitians; ſeeing it is both precious and rare, and eſpecially commended againſt Poyſon. Some think 'tis ſo called from a Perſian word *Pazar*, or *Pazan*, which ſignifies a Goat. Others think 'tis derived from the Hebrew word *Bel* which ſignifies a Lord, and *Zaar* which is Poyſon. But an Antidote is by the Arabians called *Bedſoar*, and therefore they call all Medicines good againſt Poyſon, by the general term of Bezoartick Medicaments: whence Bezoar-ſtone ſeems to be ſo called becauſe of its rare vertue againſt Poyſon.

What Bezoar is.

Now Bezoar ſtone is not digged out of the Earth, but is bred in the belly of an Indian mountanous She-Goat, ſhaped ſomwhat like a Buck or Hart, and is therefore by ſome termed the Hart-Goat. The Stones are long and round, and ſomtimes like Cheſ-Nuts or Acorns. Their colour is ſomtimes blackiſh, ſomtimes yellowiſh, greeniſh, Aſh coloured, dark Red, or blackiſh Green. On the outſide it is ſmooth and ſlippery. It is not very hard but is eaſily broken. It grows together by Scales, Scale over Scale, as an Onion is made up, upon ſome ſmal Foundation, which is commonly a little Straw or Stalk; to which a certain humor cleaves. And therefore this Stone is made up of many Plates as it were, being greater

ter in an old, leſſer in a young Goat; and all the Plates both Internal and External are ſmooth and ſhining.

Now there are two kinds of Bezoar-ſtone, the one Oriental, which is brought out of *Perſia*, *Egypt*, *China*, *Cathai*, and the bordering countries, which is more excellent then the other; the other is occidental, which is brought out of *America* and *Peru*. This Stone is very much commended againſt all Poyſons; it is given in malignant feavers, to expel Worms in Children, and againſt Melancholick Diſeaſes. *Its kinds* *Its uſe.*

Some take *Lachryma Cervi*, or the Harts Tear, to be Bezoar-ſtone. But though, as I ſaid before, the word Bezoar is uſed by the Arabian Phyſitians to ſignifie Antidotes in general; and the *Lachryma Cervi* hath a rare Virtue againſt the Plague and Poyſons; Yet Bezoar Stone and *it* are divers things. Now concerning the *Lachryma Cervi*, which he ſaies he keeps as a great rarity in his ſtudy, *Scaliger* thus writes in his *Exercitat.* 112. *It is not bred in the Hart, before he be an hundred year old. After that age it grows at the Corner of his Eye, to the bones themſelves, and becomes it ſelf a protuberant bone, of ſuch hardneſs as exceeds that of the Horn it ſelf. That part which ſticks bunching out is round, of a rare brightneſs, of a yellow colour, not without ſome ſhew of black Veins. It is ſo ſmooth that you can hardly feel it, and it ſlips from between your Fingers, as if it could move it ſelf. It is an excellent remedy againſt Poyſon. Its given to ſuch as are taken with the Plague, with a little Wine. Whereby ſo great a ſweat is cauſed, that you would think the Patients whole Body were well nigh Melted.* Touching Bezoar Stone ſee a peculiar Treatiſe of *Caſparus Bauhinus*. *Lachryma Cervi:*

Moreover, of this kind there is Coral, *Lithodendron*, or Stone-tree, being a Sea-ſhrub, which when it is taken out of the Water turns to Stone. The reaſon whereof is, becauſe there is much Salt and Stone making juyce in the Plant: which the Chymical reſolution thereof ſhews, for all the coral well near turns to Salt. *Coral:*

And this is the common opinion of all Authors well-near, touching the Generation of Corals, who hold that Coral is ſoft under this Water, and afterward grows hard in the Air. Yet *Beguinus* in *Tyrocin. Lib.* 2. *Cap.* 10. queſtions the truth hereof, and ſaies it is a Fable, and relates from the report of credible witneſſes and certain experiments, that Coral is as hard in the Sea and under the Waters, as after it is drawn out into the Air.

There are three ſorts thereof: Red, Black, and White. The beſt is the Red and that which hath many cluſters. It Binds, moderately Cools; Cures the flux and vomiting of Blood, the *Gonorrhœa*, and Whites in Women. It helps the Falling-ſickneſs and is a ſtrengthener. *The ſorts thereof:* *Its Uſe:*

To this family alſo belongs the Stone *Ætites* or Eagle-ſtone, ſo called becauſe 'tis believed that the Eagle carries it to her Neſt to help her bringing forth of her young ones. It contains another ſtone within it. 'Tis found in many places: the Orientals ones are beſt. But they are found alſo in *Saxony*, *Miſna* and *Sileſia*. 'Tis thought to further Child-birth and to prevent abortion. To prevent abortion they tie it to the Womans Arme: to further Child-birth, to her thigh. *Eagle ſtone*

There are alſo other Stones found in Living Creatures, as the Cock-ſtone, the Swallow-ſtone, the Toad-ſtone, Crabs-Eyes ſo called, Carpe-ſtones, Perch-ſtones.

Before, *Lib.* 5. *Chap.* 2. among the ſorts of Alum mention was made of the ſtone *Amianthos*, which is commonly cal'd *Alumen Plumoſum*, Fetherd Alum, and ſold under that Name; but it belongs rather to this place. In daies of old it was made into Thred and Woven into Coverlids as if it had been Wooll, and thereof they made Funeral Coates for the Bodies of Kings, that the Aſhes of their burnt Bodies might be thereby ſeparated from the other Aſhes. But the manner of weaving the ſame is at this day unknown. *Amianthus.*

Of this Family alſo is *Hæmatites*, the Blood-ſtone, eſpecially good to ſtop bleeding. *The blood ſtone.*

Now come the Nobler Stones and Jewels. In the firſt place, the fragments of five precious Stones are known and uſed in the Apothecaries ſhops: and thoſe Stones are the Sapphire, the Hyacinth, the Sardius, the Granate, and the Smaragd.

The

the Sapphire. The *Sapphire*, in the first place, is of a Sky-colour, like the Heavens on a cleer day. The whiter Sapphire is called the female. It resists Poyson and strengthens. Being worn it hinders Pestilential Carbuncles from breaking forth, and laid upon a Carbuncle it extinguishes the same, and hinders venemous exhalations from passing thence to the Heart: being worn by a lascivious Person it looseth its brightness and beauty. It hinders fleshly desires, also 'tis commended against Diseases of the Eyes, and is said to strengthen them.

the Hyacinth. The *Hyacinth* is of a yellowish redness, and glisters as it were Gold, and imitates the flames of Fire. It is commended to cure the Plague, being worn in a Ring or hung about the Neck.

the Sardius or Carneolus. The *Sardius*, so called because first found at *Sardis*; also *Carneolus*, Cornelian, because in colour it resembles bloody water wherein raw flesh hath been washt. The Sardius worn is said to recreate the Mind, to drive away Fearfulness and sad Dreams; to which intent it goes into the Electuary *de Gemmis*. Being drunk with harsh red Wine it stops the Courses, and Blood flowing from any part of the Body.

the Garnet. The *Garnet* is red, but with some yellowishness resembling Fire, and it hath the colour of Vermilion. 'Tis said to strengthen the Heart, and resist Sadness and Melancholly.

the Smaragd. The *Smaragd* is a most neat Jewel, the most excellent of all green precious Stones, and by its pleasant Greeness it refreshes and recreates the Eyes. It is given against Poyson, and the bitings of venemous Beasts, and pestilential Feavers. Being tied to a Womans Hip 'tis said to further Child-birth; and being laid on her Belly to prevent Abortion. It is contrary to all Venereal matters, and if it touch the Skin of the Man that is in his carnal Embracements, 'tis said to break asunder. Worn in a Ring or hung about the Neck it preserves from the Falling-sickness.

the Adamant or Diamond: There are also many other precious Stones and Jewels. The *Adamant* or (as we say) Diamond, is so called, because it is unconquerable by Iron or by Fire. For it is the hardest of all Jewels, transparent like Water. Rare virtues are by many attributed to the Diamond; and it is said to be an Amulet against Poyson and Witch-craft, frightful Dreams, and the Night-Mare; and to resist pestilential Causes.

the Carbuncle: The *Carbuncle* hath its name from a burning Coal: It is commonly beleevd to give light in the dark, but there is no Eye-witness thereof. And therefore learned Men conceive, that if there be any such Jewel as a Carbuncle, it is a great and a noble one.

the Ruby. The *Ruby*, whose brightness and flaming redness shines above other stones. It resists Poyson and putrefaction, preserves from the Plague; it drives away sadness and fearful Dreams, and exhilerates the mind.

the Granate. *Granates* or *Garnets* are as it were imperfect and rude Rubies, of which we have spoken before.

the Amethyst. The *Amethyst* is so called, because it is thought to prevent Drunkenness, it is of a violet color, mixt as it were with Purple.

the Opal. The *Opal* is an exceeding beautiful Stone, which alone hath in it all the colours of other precious Stones. For there is in the Opal, as *Pliny* in his 37. *B. ch.* 6. writes, the thin fire of the Carbuncle, the bright purple of the Amethyst, the Greenness of the Smaragd, all shining together with an incredible lustre. And therefore it cannot be counterfeited, as other precious Stones may. And as it hath the colours of all other Stones, so it is thought to have all their Virtues. But it is most commended for preserving the Eye-sight, being worn.

the Topaz or Chrysolite. The *Topaz*, which is now called the Chrysolite (though some difference them by the brightness of the colour) receiveth it name from its colour: for it is a Jewel transparent and of a Golden color. It is commended to strengthen the Heart and to drive away Melancholly: but is especially used against the Falling-sickness, and applied to Wounds to stop the Blood.

the Beryl. The *Beryl* in its color represents the Greenness of the Sea when it is calm, or the colour of a watry Hyacinth. It is chiefly commended for Wounds in the Eyes, being reduced to most fine Powder.

the Crystal. The *Crystal* indeed was named by the Ancients from Ice, and therefore some have held that Crystal is made of Ice frozen together upon exceeding cold Mountains. But this is false. For Crystal is generated also in *Cyprus*, and other Mountains, where Heat is never wanting. Again it wil not melt with Fire, as those things use to do which are frozen: but the Fire reduces it into Earth and Salt. And doubtless it is coagulated by a Salt spirit of stone-making juyce. Being made into fine Powder, and given with Honey in Wine or Broth, it is said to encrease Milk by a propriety which it hath. Held under the Tongue

it quenches thirſt. A dram taken with Oyl of ſweet Almonds is a preſent help for ſuch as have taken Mercury Sublimate. Alſo it cures the bloody Flux, and the Whites in Women.

The Jaſper.

The *Jaſper* is of many colours, and therefore they make divers kinds thereof. That which is reddiſh is much commended againſt a Flux of Blood from the Noſe, Womb and Hemorrhoides; Yea, and it is alſo commended for Wounds: and credible perſons report, that a Flux of Blood and the Womb Flux, which could by no means be ſtopped, hath been ſtaid by a Jaſper Stone bound to the Womans Thigh; as alſo Noſe-bleeding that no other Remedies would cure, hath been ſtopped by hanging the Jaſper Stone about the patients Neck. Alſo 'tis commended to cure the Falling ſickneſs, if it be worne upon the Mouth of the Stomach.

The Nephritick Stone.

Some few years ſince there hath been brought out of new *Spain* a Stone called *Lapis Nephriticus*, the Kidney-ſtone; which is juſtly counted as a kind of Jaſper. Its Surface is alwaies fat, and as it were ſmeared with Oyl. There are ſundry kinds thereof in reſpect of colour. For the moſt part it is of a whitiſh Green. It is commended againſt pains in the Kidneys, from whence it had its Name; and being tied to the Arm it has a wonderful Virtue, yet confirmed by experience, to break the ſtone and drive it out by Urine: of which later Phyſitians that have written of the ſtone, do every where ſpeak.

The turcoiſe.

The *Turcoiſe* is a Stone, not tranſparent, yet of a very pleaſing colour, being a mixture of green and blew. It is believed to ſtrengthen the Heart and Spirits. But eſpecially they attribute thereunto admirable Virtues to preſerve a Man from falling. For if a Man be any waies in danger of a fal, and wear this ſtone, it preſerves him harmleſs; and they ſay the Stone it ſelf will break or loſe its Colour and grow Pale, when the party is in danger of a fal. The ſame it wil do, they ſay, when the wearer is not well.

Lapis Lazuli.

Lapis Lazuli ſo called by the Arabian Phyſitians, and by the Greeks *Cuanos Lithos*, is alſo a Stone that is not tranſparent, of a deep blew color adorned with Golden ſpecks. This Stone hath a rare Virtue to purge Melancholy Humors, and therefore it helps Diſeaſes ſpringing from that Humor: of which ſee the writings of Phyſitians. Of *Lapis Lazuli* is made that moſt excellent blew colour, cal'd *Ultramarinus*, which is dearer then Gold. Alſo Gold is got out of the ſaid Stone. And even this Stone alone doth teach us, that there is one common principle of Metals and Stones, as was ſaid before; and that the matter of Metals doth ſuffer many mutations, and that thence various Minerals may be generated, each of which hath a peculiar affinity to that Metal to the generation whereof the matter was diſpoſed: which I leave to the diligent conſideration of others.

Metals & Stones have the ſame common principles.

Lapis Armenus.

Lapis Armenus is in colour and Virtues of kin to the former. But this is not ſo hard as the *Lapis Lazuli*, nor is it adorned with ſpecks of Gold, but with many green, blew and blackiſh ſpecks.

Pearls.

Finally, let us conclude this our Doctrine of precious Stones with *Pearls*; which are not indeed generated in the Earth, as other Jewels are, yet are as precious and Noble as they.

Now they are bred in certain Shel-fiſh, of that Humor whereof the Shel of the ſaid Fiſh is made. The moſt excellent are found in the Perſian Sea, and in the Regions of *China* and the *Eaſt Indies*: the occidental Pearls becauſe they have not the Silver glance of the other are of leſs value. Now Pearls have a rare faculty to ſtrengthen a Man, and to reſtore his Spirits; and therefore they reſiſt Poyſon, Putrefaction and Peſtilential Feavers, they chear the mind, they are a Remedy for ſwooning, and Melancholick Diſeaſes. They are good againſt a flux of Blood and looſneſs of the Belly, they do ſtrengthen the Brain and Nerves. Mixt with Eye-ſalves they ſcour away the Clouds and Filth of the Eyes, and conſume the dropping moiſture thereof.

But ſo much may ſuffice to have ſpoken in brief of Stones and Jewels. You may ſee more in thoſe Authors who have wrote peculiarly of this ſubject, as *Franciſcus Rueus*, *Georgius Agricola*, *John Kentmannus*, *Andreas Baccius*, and eſpecially *Boetius*, who has publiſhed an excellent Hiſtory of Stones.

CHAP.

Chap. 5. *Of Metals.*

The Aristoteleans opinion concerning the matter of Metals.

NOw concerning the generation of Metals the opinion of Authors is various. And as to the matter of Metals, the Aristoteleans do hold that as all other things digged out of the Earth are made of a Smoaky exhalation, so all metals do spring from a vaporous Exhalation, and that moisture is prevalent in them, because they may be Melted and Hammered. And they teach that Metals are generated, when a Subterraneal Vapor included, especially in Stones, in regard of a dry Exhalation which drew it upward, is gathered into one, and Coagulated like Dew into very smal drops, which cannot be done without cold: yet with this difference; that in the Generation of Dew and Hoar-frost the foresaid driness which carried the Vapor upwards is separated: but in the generation of Metals that same separation is not made, but the dry Exhalation is contained and Coagulated with the Vapor.

Howbeit, this opinion is not to be received unless it be otherwise explained. For it supposes a matter too remote, and speakes of the generation of Metals, as if it spake of Meteors. And those who hold thus concerning the Generation of Metals, seem to be of his mind, who intending to speak of the Generation of Animals, should make, not Blood and Seed, but an Exhalation Dry or Moist, the principle of Living-Creatures.

The opinion of the Chymists.

The Chymists therefore do better, who having more diligently sought into the Generation and Resolution of Metals, hold their principles to be Sulphur and Mercury; to which later writers have, not without Cause, added Salt, or a Metalline, Copperasated, or Vitriolated Earth: and that in all these a Formative and Seminal Faculty was at the Creation implanted by God the Creator; which as *Scaliger* *Exercit.* 307. *Sect.* 20. is a certain fift essence far different from the four Elements, and which as the principal agent makes Metals of matter thereto disposed. And therefore wherever this Seminal Principle is wanting, no Metal can be made of any Exhalation, Dry or Moist, by the power of any efficient whatsoever.

And that the Matter thus stands, is apparent from the Metal mines, the meltings, Probations, and resolutions of Metals, and the very Proprieties of the Metals them-selves. For in all Mines these principles are found, and out of all the Oare where-in all Metals are Generated, Sulphur is boiled. Also 'tis very well known to Chymists, that Metals may be changed into running Quick-Silver, and that of Quick-Silver Metals may be made. Yea any man may judg by his Nose and Eyes, that there is Sulphur in metals; because in the Calcinations and melting down of Copper and Iron, a greenish and reddish flame is seen, and there is a smel of Brim-stone. And most Diseases wherewith diggers and refiners of Metals are troubled, have their original from Sulphur and Mercury. The Resolution or Dissolving of Metals shews the same, which is not into Dry and moist Exhalations only, but into things of kin to Metals, retaining their own Nature and properties, in sundry alterations and external Mutations. For Lead being turned into Cerus, although it seem to have quite put off its Nature, yet may it be melted into Lead again. Yea and *Stibium* doth turn again to Antimony without much ado. The specifical proprieties of Metals do argue the same, which witness, that they have not their original only from the mixture of Elements. For that which is true of the Load-stone, as *Scaliger* writes, that it cannot by any faculty of the Elements draw Iron: the same may be said of many proprieties and operations of Metals.

And the Mercurial matter is the chiefest in the Constitution of Elements; which being sundry waies mixed with fixt or volatile Sulphur, and a copperasated Salt or Earth, makes sundry sorts of Metals. And the Chymists do commonly call Mercury the Mother and Feminine Principle, and Sulphur the Father and Masculine principle. Now with Sulphur is mingled Vitriol or Metallick Salt; and in Sulphur there is Vitriol, and in al Vitriol, Sulphur: whence it happens, that out of both there is a Spirit drawn much alike.

But

But that others do think otherwise in this point, the chief cause is; inasmuch as these principles are not alwaies found in mines after the same likeness and form as they imagined. Moreover, because metals are not found every where and in all places in which Quick-Silver and Sulphur are found. And Finally, because they cannot sufficiently discerne these principles in Metals. For they think it necessary, that in every Mine of Metal these principles should be found with the Metals, but especially that Metals ought alwaies to be found in the Veins of Mercury and Sulphur: and if Sulphur were in Metals they conceive it must needs flame.

But unless they were blinded with the darkness of Chymical Ignorance they might easily see those principles in Metallick Veins. For they do not alwaies appear under one and the same visible form and shape; though sometimes they are found in the mines, in the very same shape: but sometimes they wander in the shapes of Exhalations and Spirits, sometimes they are Coagulated into the form of a Juyce, an Earth, or some other form. Yea, and the Metals themselves are found sometimes Fixed, other whiles Volatil. For Nature Generates Mercury after a Spiritual manner; to which if a Copperasated Sulphur be added, and a formative principle, it is Coagulated into a Metal. But if Sulphur and the formative Principle be wanting, it grows together into a peculiar matter and is found alone. For one of these doth not suffice to make a Metal, but all of them are requisite. And therefore in such Mines, in which one is present and the rest are wanting, Metals are not generated. But there alone Metals are bred, where a Sulphureous Vitriolated fixative Spirit is exactly mixed with Quick-Silver in a matter fit to become a Metal. Those Bodies do not make Metals, but the Spirit must of necessity be mingled most intimately. But in this formation, before they grow quite firm and Dry, and come to Maturity, they are often found in the likness of a Mineral Juyce, and unripe Metal: and at last they are Coagulated and compacted into a perfect Metal.

And they that are stumbled at the inflameable Nature of Sulphur, must know, that there is no necessity that Metals must take flame because they have Sulphur in them. Simple Water Wets, but it doth not so in compounds; Air ascends upwards, but not in mixed Bodies. Again, they are ignorant that an inflamable and Volatile thing may so be fixed, that it shall take flame no more. For it is the property of all Sulphur to be inflamable, but not at all times: and the more it is fixed the less it conceives flame; and the more it is fixed, the less subject Metal is to burn. Hence it comes to pass, that Iron and Copper are burned, and send forth a notable flame: but Gold by reason of the fixedness of its Sulphur withstands the violence of Fire.

The efficient cause of Metals.

From hence also, it is easie to judg of the Efficient cause and active principle in the Generation of Metals. For they who conceive that Metals are Coagulated only by cold do discover their own simplicity of wit, or their unskilfulness in the point of Metals: seeing Metals have already an internal Cause of their Coagulation, and are dissolved by heat; cold only gives occasion of their Coagulation. But if that internal Cause of Coagulation be wanting, no external cold is sufficient to Coagulate the same. Which is to be seen in Quick-Silver, which no cold can congeal, and yet it is Coagulated with the Spirit of Lead. Yea, in the very Fire it self, by Cementations and other Coctions, Coagulation and fixation is made.

We ought therefore, touching the Nature and original of Metals, rather to credit the Diggers, Refiners, and Triars of Metals, and the Chymist, then idle disputers, Ignorant of the Nature of Metals, Who, out of an hatred to Chymistry, do endeavour (by I know not what Reason) to perswade us otherwise. And therefore the most learned also of the Peripateticks, who have searcht more deeply into the Nature of Metals, do in this point follow the opinion of the Chymists.

The Affections of Metals.

Now the Common Affections of Metals are, to be melted with heat; to grow hard again by cold; to be hammered and beaten out, to drink in Quick Silver; to be dissolved by *Aqua-Fortis*.

They flow and melt by Reason of Quick-Silver: and therefore those who have most part Quick-Silver are more easily Molten; but those more hardly, in which Sulphureous dryness and Salt are most prevalent. And if there be good store of

Mercury in Metals they become so soft, as to be melted by the very least heat; Contrariwise, such as are often burnt in the Fire, their Mercurial moisture being taken away, they become at last hardly Meltable; as also if they be steeped in Aluminous, Copperasated, and fixatory Waters.

Also malleableness depends upon the Mercurial Humidity. And those Metals may be best hammered and spred abroad by beating which have a Mercurial moisture most exactly mixed with a Sulphur proportionable. Contrariwise, those in which there is most of a Vitriolated Sulphur, of Salt and Metalline Earth, they are least Malleable.

Now Metals do drink in Quick-Silver, because they have one Root, and their substances are of kin; as we see Oyls easily mix'd with Oyly things, and Water with things Watry.

Difference of Metals. Metals are by others otherwise divided: but they are by the Chymists usually divided into Perfect and Imperfect. And they count that perfect which is compleat both in Substance and Accidents, and excellently fitted for use. Such an one (Namely) as hath a subtile Mercurial Substance, a most ponderous Nature; that endures the Fire and all the trials thereof, without even the very least detriment; it is easily joyned with Mercury, and most easily and largly dilated. Al which marks, since they are most to be found in Gold, it is by the consent of al Nations reputed the most excellent and perfect Metal. Whereof nevertheless you may read what *Mirandulanus* saies, in his *Book de Auro*.

Whether Metals differ specifically or not. Now a Question is here raised, whether Metals differ specifically, or not. Very many Chymists hold, that they do not specifically differ, but only in degrees of perfection, and that they consist all of the same matter; have the same efficient Cause; are generated in the same place: that in Lead there is alwaies some Gold found; in some Brass there is Gold; and divers of them are commonly bred together; they are mutually changed one into another, as Iron into Copper; out of all Vitriol is made, and all are resolved into Mercury. Hence doubtless were these sayings of the Chymists: *Lead is Leprous Gold*: *the Inner parts of Silver are Gold.*

Yet, If I may speak mine own opinion, I conceive that Metals are specifically different. For though it may rightly be said that al have one and the same matter, not only generical and remote, but also immediate (in which respect they differ from other Natural things, and for which cause it is that they are turned one into another, and divers generated at once in the same place) yet have they not the same Ultimate matter; but therein they differ. Yet neither are they differenced only by accidents, but by a substantial specifick form, and there is one form of Gold, another of Iron, and another of Lead, which disposes and Labours that common matter according to its own Nature, which appears by the effects and operations. Hence it is, that though all of them are resolved into vitriol and Mercury; yet that Vitriol which is made out of Copper differs not a little from that made out of Iron.

Nor is that of any moment which some Chymists say; that Nature alwaies intends that which is most perfect. For this is true in every kind. In the kind of Men, Nature intends to make the perfectest man; in the kind of a Vine, the most perfect Vine; in the kind of Gold, the most perfect Gold. Yet doth it not therefore follow that because Gold is the perfectest Metal therefore Nature alwaies intends to make Gold. For that is just as if a Man should say, that Nature in the kind of Animals alwaies intended a Man, who is the most perfect of al Live-Creatures. And if Nature alwaies intended Gold, why is there no more to be found? Now they hold that there are two perfect Metals, Gold and Silver: and four imperfect ones.

Gold what it is? Gold is the most perfect of all Metals, consisting of the most pure Mercury, most perfectly digested and ripened, by Virtue of a most excellent and fixed ruddy Sulphur, wherewith it is most exactly mixed and united. Hence it comes to have a yellow colour; it is most weighty of al Metals, it indures the Fire, it may be beaten out exceedingly thin. and it is most easily of all Metals united to Mercury. The Chymists do call it *Sol*, the Sun.

Silver, what? Silver is a perfect Metal, yet more inferior then Gold, consisting of a Mercury almost

almoſt fixed, and of a white Sulphur, almoſt fixed alſo. For it is neither ſo heavy nor ſo fixed as Gold. And therefore although it endures the Fire after a ſort, and abides in the Aſhy Cement, yet doth it not endure in the Royal Cement, Antimony, Sulphur. Next to Gold it is beaten to the greateſt thinneſs of any Metal. The Chymiſts call it *Luna*, the Moon.

Imperfect Metals are thoſe which have principles not ſo mature and wel digeſted, nor ſo fixed and pure: whence it happens, they can neither endure the thunder of Lead. nor the Cement, nor Sulphur, but flie away in ſmoak and ſparkles, or are changed into droſs, Glaſs, Stones.

Now they are hard or ſoft. The hard are thoſe which by Reaſon of their Earthy Sulphur and hardned Mercury are firſt red hot before they melt; the ſoft are thoſe which by Reaſon of a moiſter Mercury and leſs digeſted are firſt melted before they are Red Hot. The hard have more Sulphur then the ſoft; but it is Earthy and contains more vitriolated Juyce. And therefore they are eaſily turned into Vitriol. Hence it comes to paſs, that they ſuffer detriment by Fire, and will not endure the tryal of more perfect Metals, but Fly into the Air.

Now the hard Metals are two, Braſs or Copper, and Iron. Braſs is an imperfect Metal, Hard, conſiſting of a little Mercury and very much impure Red Sulphur, not perfectly ripened, for the moſt part but yet not perfectly fixed; being of a reddiſh colour. And hence, by reaſon of its Sulphur, it is thought to have affinity with Gold, and to contain in it the principles and Seeds of Gold; and it is believed that by digeſtion it may attain to ſome maturity and perfection. Alſo it hath affinity to Silver; ſeeing in the Marchaſite and the *Lapis Fiſſilis* they are oftentimes found both together: and Silver and Copper being diſſolved are both of a blew colour. The Chymiſts cal it *Venus*. *Braſs or Copper.*

Iron is an imperfect Metal, conſiſting of a little Mercury and much fixed Sulphur, being of a whitiſh black and Blew colour. Hence it comes to paſs, that it is exceeding ſlow in melting, and bears long the force of Fire; and is readily calcined. Alſo it is hardly Joyned with Mercury, becauſe there is little Mercury in it. Alſo it hath little Vitriol, and therefore it is of a whitiſh livid colour. The Chymiſts cal it *Mars*. *Iron.*

The ſoft Metals are, white Lead which is called Tinn; and Black-Lead which is called ſimply Lead.

Tinn or white Lead, is an imperfect Metal, ſoft and white, conſiſting of much Mercury, leſs pure and fixed then in the perfect Metals, but purer and more fixed then in Black-Lead, and of a white impure and unripe Sulphur. Being mixed with Gold and Lead it leaves them malleable; but being mingled with the other Metals it makes them break under the Hammer. The Chymiſts call it *Jupiter*. *Tinn.*

Black-Lead is an imperfect Metal, Soft, of a livid colour, generated of much impure and undigeſted Mercury, and of a little Sulphur impure likewiſe and ſtinking. Hence, being uſed in the trial of perfected Metals it conſumes the imperfect, and carries them away with it ſelf in Smoak, or turns them into droſs. It is of all Metals the moſt eaſily melted. The Chymiſts cal it *Saturn*. *Lead.*

Finally, Of kin to Metals is Quick-ſilver, a Mineral Liquor, of a wonderful Nature, for it flows like Water, and yet it wets not. It is the weightieſt of all Minerals, and wil ſuffer nothing to ſink into it but Gold. Now it conſiſts of a clammy Metallick Water, and a Sulphureous Earth, exactly mingled; and it mingles with Metals, firſt with Gold, then with Tinn, then with Lead, then with Silver; hardly with Copper and Iron. The Chymiſts call it Mercury; becauſe as Mercury aſſociates himſelf with all the Planets, ſo doth Quick-ſilver with all Metals; and becauſe its Nature is moveable and ſhifting, which hath hitherto ſufficiently exerciſed many Chymiſts, and is not yet ſufficiently underſtood. And therefore hardly can we ſay any thing thereof in this brief diſcourſe. *Quick-Silver.*

And here to conclude our Diſcourſe of Metals, we muſt not paſs over that controverſie concerning the tranſmutation of Metals. Out of which briefly to unwind our ſelves, ſeeing, as *Ariſtotle* rightly judges, it is a certain weakneſs of mind to ſeek *Whether the Tranſmutation of Metals be poſſible.*

seek for Reasons and let go Sense; I conceive the shallow Reasons of some Persons unskilful in Chymistry are no waies to be preferred before experience. Now it is a most known thing, that in *Hungaria*, at a Town called *Smolnits*, in the Mountain *Carpathus*, there is a Fountain, whereinto Iron being cast is turned into very good Copper. The like is done at this day in *Goslaria*. Nor is this performed by Natural Waters only, but the same may be done by Art also. For if Iron be cast into vitriolated Water there sticks a red pouder thereto, which being melted in the Fire becomes Copper. So Quick-Silver is turned into Lead, with no great pains. Also it hath been often found true by experience, in this Age of ours, that other Metals may be turned into Gold: and it is Notoriously known, what that famous *Alexander Sidon*, a Scotchman performed at *Colenius Basil*, and others places. Concerning which matter see the Historis of the Metallick Transmutation described by *Ewaldus de Hoghelande*; and the writings published by *Andreas Libavius*, for defence of Transmutatory Alchymy.

Since therefore by Experience it is sufficiently manifest; we need not dispute long of this Matter. One thing we shal briefly hint. That the Transmutation of Metals is not Simply and Barely Artificial, save as it applies things Natural to perform some certain action. Nor doth the Art proceed upon any but meerly Natural principles; and such things as Nature hath generated she doth only mix after a certain Fashion.

THE

THE SIXTH BOOK.

Of the Soul in General, and of things Vegetable.

Chap. 1. *Of the Soul in General.*

whether there be a Soul or no?

SInce Method requires that we should now treat of Living and Animal Things; we must first speak of the Soul. That there is such a thing as a Soul, is manifest by the operations thereof. For we see that Living things perform many operations which they cannot do when they are dead. It follows therefore that the Body it self cannot be the cause of those operations; but that there is somwhat in the Body which performs the same. Now since every operation is a kind of transient accident, never firmly subsisting in it self; there must needs be in the Body some cause, which is the stable and constant producer of actions; which being present, life and every action is performed, and when it departs, the life ceaseth: and this cause of such like actions is termed *Anima*, the Soul.

As to what concerns the Essence of the Soul, I omit the sundry Opinions of the Ancients, which are reckoned up, and largely refuted by *Aristotle*, *Lib.* 1. *de Anima*. Marsilius Ficinus, *Lib.* 6. 7. 8. *Theologiæ Platonicæ*. And I shal retain the Definition of *Aristotle* in 2. *de Anima*, *c.* 1. *text.* 6. which is this, *A Soul is the first act and perfection of a Natural Body, which hath an aptitude to Life*; or briefly, *of a Natural Body, whose parts are Organs*. For the Soul is neither an accident, (seeing an accident cannot be one part of a compounded substance, such as a living Body is, nor the first principle of all actions, or make a true difference betwixt two substances;) nor a Body, for two Bodies cannot be in one place: But it is the act, or substantial form, by which a living Body is a living Body indeed; that is to say, by which it hath an inbred power and faculty to perform all the actions of Life. More may be seen touching the word *Entelecheia* used in this Definition, in Book 1. ch. 9. concerning Motion, where I have at large explained the genuine signification of this Word.

The Definition of the Soul.

The Soul is neither an accident, nor a body.

Now a Soul is not the perfection and form of any Body, not of an Artificial, but a Natural Body; nor yet of every Natural Body: For every Natural Body is not animated; but that Body only, which hath an aptitude to exercise the actions of Life, and is so disposed that the Soul may thereby, as by Instruments, exercise its actions. For here we must hold out of *Aristotle*, in 2 *Metaphys. com.* 31. That the action of an Agent does not proceed from the subject without a form, nor from the form without a subject: for otherwise the subject and its form would be actually two things. Now if so be action cannot be performed by a subject without a form, nor by a form without a subject, much less can it be performed by Instruments without a Working cause. From whence it follows, that Action is performed by a certain compound of Matter, Form, and Instruments; so that the whol Compound may be called the Principle which acts; but the Form, the Principle wherewith the act is performed, because the Compound acts by vertue of the Form; Finally, the Instruments, whereby; seeing the operation is performed through their subserviency.

Moreover, There is also another Definition of the Soul in *Aristotle*, in 2. *de Anima*, *cap.* 2. *text.* 18. which is this: *Our Soul is the Principle whereby we live, move, use our Senses, and understand.*

Another definition of the Soul.

And seeing there are many kinds of Living Creatures; we shal best come to the knowledg of their Differences, by observation of the effects and operations of the Soul; since every

cause discovers it self by its effects, and the form by its operations. Now the proper Energy of the Soul is Life, which as the second act, is evermore attended upon, and companion to the Soul as the first act. We may therefore from the distinct manners of Life constitute the distinct sorts of souls and animated things. Now a man lives, and so do other Creatures, and so do Plants, but each of these after a peculiar fashion. The life of Plants consists in Nutrition only, and the action proper to each one, but Plants have no Senses: the life of Brutes, besides Nutrition and action, contains also sense; and each sort of Bruits hath its proper action: Finally, Man besides al these, does also understand, and make use of Reason.

Three distinct sorts of Souls. There are therefore three distinct sorts of Souls: all which are in Matter, and do constitute a living Body: Yet one of them is more loose from the matter, but another more plunged therein; and one can receive the spiritual and immaterial species of things, wherein consists the force of knowledg, but some cannot. Plants are nourished, and understand nothing; Bruit Animals can understand some things; they receive immaterial species, howbeit with some conditions of the matter: For what things they perceive are here present, and at this time; seeing Sense is busied about particulars. But the rational Soul receives immaterial species or representations of things, even without all conditions of matter.

Whether the Faculties of the Soul differ therefrom, and how? And seeing the soul is the cause of various actions, and hath the power to perform sundry operations in living Creatures, we must consider how the powers or faculties of the Soul are related to the Soul it self. And here some hold, that the faculties of the Soul are the very Essence thereof, which according to the sundry actions whereof it is the cause, hath sundry names: others contrarywise do conceive that the faculties and powers of the soul, as all others, are qualities of the second sort, and that they are really and essentially different from the soul. And this latter Opinion is the better of the two. For the Powers and Faculties of the Soul are indeed only properties and inseparable accidents thereof, and essentially distinct therefrom. For the Soul is a substance, but these are accidents or aptitudes and propensions to operate; which flow from the essence of the Soul, as their first cause, only by emanation, and so depend thereon, and are received without any medium, in the same animated Body, wherein the Soul is. For every power is ranked amongst the second sort of Qualities: and seeing the Powers of the Soul themselves are distinct one from another, they must also differ essentially from the Soul: For if they were the same with it, they would be the same one with another. Howbeit, it is to be observed, that the faculties are not mediate Agents, or middle causes betwixt the Soul and its operations, but only conditions and aptitudes to operate: For operations proceed from the Act, and not from the power; nor is it necessary that betwixt every agent and its operation there should intercede some middle agent. For so, neither could that middle agent be the cause of action, without another middle agent: and so there should a progress *ad infinitum*, without end.

These divers Souls are with their faculties so disposed, that the upper faculty does alwaies pre-suppose the lower: but the inferior may be without the superior. The Vegetative is without the sensitive in Plants: the Vegetative and Sensitive are without the Rational in Bruits: in Man all three concur. But how the Faculties are disposed in reference to the Soul in divers sorts of Living Creatures, intricate and hard Questions are agitated amongst Phylosophers.

Whether in one living thing there is more than one Soul. For in the first place Enquiry is made, Whether in every living thing there is only one Soul, or more. For some teach, That in every living Creature there is only one Soul, and that it is furnished with all the faculties of an inferior Soul; and that there are not in Man three souls, an Intelligent, a Sensitive, and a Vegetative; but one that is endued with the powers of all three, and takes its denomination from the nobler faculty: and that so the faculties which are in living Creatures of the same sort, do proceed from one sort of Soul; but those which are in living Creatures of a several sort, do arise also from a several sort of Soul; although both here and there they have the same names, and are attended by the same operations. Others do hold contrarily; That there are distinct Souls, not only in living things of several sorts; but that more also may be found in the same living Creature; and that in Man there is not only a nutritive and sensitive Faculty, but a nutritive and sensitive Soul, and also a rational; and that where-ever the Faculty is, there is also the Soul, to which it primarily belongs.

And although both Opinions have learned and famous Defenders; yet the first which is the commoner and most received, seems to me the more probable. For since there is one specifick Essence, and consequently one only Form of every thing; therefore the Soul of every living thing, which is the Form, and principally constitutes the Essence thereof, can be but one. Moreover, it is not possible, that the principles of things, opposite one to another,

ther, and ſeveral ſorts of Souls can meet together, without uniting or confounding the Eſſences of things; or yet be ſubordinate one to another; ſeeing they are ſuch oppoſites as Logicians call *Diſparata*, and do exclude one another out of the ſame ſubject. Moreover, it is a needleſs thing to multiply ſouls; ſince one ſoul, furniſhed with divers faculties may produce all the degrees of life; and a ſoul of an higher degree, and more noble, does include the faculties of the more ignoble and inferior; juſt as the number Four includes the number Three: nor is it neceſſary, though there are in the underſtanding ſubordinate conceptions, by reaſon of ſubordinate differences, that there ſhould therefore be ſubordinate Forms, without the Underſtanding. For the multiplicity of univerſal ſubordinate conceptions does not multiply the Eſſence and Form of a thing.

Now the Principal Cauſe that others have erred in this point, hath been this; That they thought the vegetative power alone to be a peculiar Soul, and to conſtitute the ſort of a Plant; and the ſenſitive Faculty alſo to be a peculiar Soul which conſtituted the ſort of Animal: Whereas nevertheleſs there are many ſorts both of Plants and Animals; and the Plants have different ſorts amongſt them, as alſo the Animals, and there is one ſpecifical form of a Roſe, another of a Violet, another of a Willow; though the vegetative Faculty be found in all of them: one of a Lyon, another of a Dog, another of a Wolf, although the ſenſitive Faculty be common to all. All Plants have indeed a nutritive and generative Faculty, but not that only, but withal ſomwhat proper, whereby a Violet differs from a Roſe and a Willow. So a Wolf is nouriſhed, does generate, and exerciſes its ſenſes, but it does not theſe things alone, but it hath alſo ſomwhat proper to it ſelf, whereby it differs from a Lyon and a Dog; and from the ſame ſoul in a Dog does flow the Faculty of nouriſhing, of ſenſe, and of doing that which is proper to a Dog, whereby it differs from other Animals. Nor are there in a Dog many and divers Eſſences, as the Patrons of the other Opinion do erroneouſly ſuppoſe. For neither are the Vegetative and Senſitive, or the Vegetative, Senſitive, and Rational, certain peculiar general Forms, or three Eſſences; but only general conceptions, ariſing, and conſtituted out of the compariſon and conveniency of Living things, which do no where exiſt ſeparately ſave in the mind; juſt as Beeing, Subſtance, Body: and therefore they do not multiply the Eſſence of things.

Whether the ſoul be totally in the whol Body, and totally in every part.

After this Queſtion follows another: Whether the Soul be totally in the whol Body, and totally in every part? or whether it be all in the whol Body, and part of it in one part, and part in another. But firſt that ambiguity which lurks in this Queſtion, muſt be diſtinguiſhed: For the term *Whol*, may here be conſidered in a three-fold notion; in reſpect of a Subſtance, Quantity, and Quality. The firſt is conſtituted of the parts of the Soul in the ſame living Creature; the ſecond of the Subject, according to the extenſion whereof the Soul is extended, ſo as to have quantity; the third of the faculties, wherewith it is furniſhed. The School-men call the firſt, the Eſſential whol; the ſecond, the Quantitative whol; the third, the Poteſtative whol.

As to the firſt, Inaſmuch as the ſoul of every thing is ſimple, and not compounded of Eſſential parts, where ever it is, there it is totally, and ſo as that it is totally in the whol Body. For we muſt not allow of their Opinion, who hold, That the ſubſtance of the Soul is only in one part of the Body, which is the principal part; and that the reſt of the Body is governed by powers ſhed out of the Soul: For thus the whol Body ſhould not be animated, but only that part wherein the ſubſtance of the Soul is: For thoſe Faculties whereby (according to their Opinion) the reſt of the Members are governed, ſince they are accidents, cannot ſupply the room of a ſubſtantial Form. Moreover, ſince the Faculties are accidents, flowing from the Eſſence of the Soul, only by way of emanation, they cannot have a ſubject different from their Form, nor be produced in any ſubject, ſave that wherein the Soul is; and therefore where they are, there we may know the eſſence of the Soul to be. And therefore we conclude that the Eſſence of the Soul is in all parts of the animated Body, and that no part is deſtitute thereof.

Yet is not the Soul in its Body, in all animate things, after one and the ſame manner. For in Plants and ſome Animals, there is no principal Member, but inſtead of a principal Member, a certain humor is diffuſed through the whol Body, by means of which, chiefly, the ſoul is joyned to the Body: whence it is, that alſo the parts being pluckt from the Body do live for a ſeaſon. But the caſe is otherwiſe in perfect Animals, in which we muſt hold that there is ſome principal Member, wherein the ſoul, as in a Root wherein it is naturally inbred as it were, may reſide, and pour it ſelf out to the other Members. And therefore that principal Member being hurt, the Animal ſoon dies; but not if any other be hurt; and the Members pluckt from the Body, do preſently die.

Secondly, If we enquire how the Soul is in the Body, in respect of Extension and Quantity, the Answer is briefly this: That every form which informs the matter and is united thereto, and makes up one compound therewith, is extended according to the extension of the Matter. Concerning which thing it is nevertheless to be observed, that only Matter is of it self furnished with Quantity, and divisible; but that the Soul of it self is neither subject to Quantitity, nor to Division. In the mean while, because it informs the whol Body, it is rightly said to be coextended therewith, and that where ever the body is that lives, there also the Soul is. Hence the Body is properly said to be divided, and to be made greater or lesser; and the Body of a Plant, from a smal Twig, grows to a tall Tree, a Calf to an Ox; and a Body in a Consumption grows less, and so doth a Tree whose boughs are cut off. But it is not so with the Soul; nor is that Soul which is in a smal branch, less in it self, than the Soul which is in a tall Tree; nor is the Soul of a Calf less than the Soul of an Ox, but remaining the same, it spreads it self abroad into the additional nutriment; nor is a Plant or Animal the less by communicating it self in generation; nor when the branches of a Tree are cut off, is the Soul of the Tree the lesser; nor hath an Animal that is consumed a lesser Soul than that which is corpulent. For the Soul is joyned to the dimensions, partly as colors, partly after another manner. For it informs the measured quantitative Body, and its plenitude and fillingness is as great as the Body it self and the dimension thereof. Aud though we suppose the Body to encrease never so much, the Soul without any addition wil fil it al; and if it be diminished never so much, it wil fil no more than that little Body. Of it self therefore the Soul hath no Quantity: but in respect of dimensions whereto it is joyned, it hath such a property, that it fils no more than the Body, be it great or little. And though notwithstanding by accident its plenitude is restrained and contained: yet is it not cut in sunder or diminished. In which particular it affords a certain resemblance of the most good and great God, who as *J. Cæsar Scaliger* speaks, Reigns every where without place, is all without all, and the whol without parts.

Finally, Since divers and sundry powers do flow from the Soul; the Question is whether the Soul have all these powers together, in al the parts of the Body. We answer: That in al the parts of the Body, there are al the faculties according to their Original; and that the Soul brings al its faculties into al parts of the Body: yet peculiar faculties are only received in peculiar parts as in their subjects. For the Soul indeed is in al the parts, which is the Original of al the faculties: yet such is the nature of proper accidents, that it exists from a principle or certain cause; yet they insist only in a certain Subject. Hence *Scaliger Exercit.* 103. *s.* 37. *You shal see some doubt, whether Memory be in all parts of the Body. Nay I tel thee, the Understanding is in the Feet. For we have one Soul every where attended with its faculties, as being essential thereunto. But where there are Instruments, there the faculty exercises its act. For if there were an Eye in the Finger, the Finger would see by that Eye, without calling any power or faculty from the Brain.* For the Soul which is the same in al parts of the Body, is indeed every where furnished with the same faculties; and hath in al members the power to do whatsoever is proper to it; yet it performs certain actions by certain instruments; it sees by the Eye, hears by the Ears, smels by the Nostrils.

Which is the Principal part of the Body.

But because we are fallen upon mention of the principal part, and the foregoing Question can scarce be rightly resolved, without explication of the Controversie concerning the principal member in man and other sanguine Creatures, we must not omit to handle the same. For it is one and the same Question, which is the Seat of the Soul, and which is the principal member. For the principality is to be assigned to that member wherein the soul doth chiefly reside. Now that there is one principal member Phylosophers and Physitians agree, though they contend sharply which it is: and reason perswades the same. For since the soul is not the form of an homogeneal body, but of a body heterogeneal and organical, which hath many and different parts: there must of necessity be some order established amongst them, and we must beleeve that one of them is more worthy than another: and since as hath been said, the Hand, Foot, and other members being cut off, die presently, the rest retaining life, we must needs think that the Soul hath more affinity to one than another. But what that principal member is, the Platonists, to whom *Galen* and many Physitians joyn, are at variance with the Aristotelians or Peripateticks.

Plato and *Galen* hold three chief Parts, the Liver, Heart and Brain, and they assign the principality to the Brain, because therein is the principle of Sense and motion, and the rational soul hath there its residence. Contrariwise, the Peripateticks hold the Heart to be the principal member.

But

But several men seem to have several respects in their assigning the principal part. *Galen* hath respect to the nobility of the actions; but the Aristotelians respect the Radication (that I may so speak) of the Soul it self. The Physitians count the animal faculties, so called, most noble; the Peripateticks make most account of the Action of the Heart, because thereby all the rest are cherished and governed. And therefore though we may grant Physitians, that there are three chief members of the Body: Yet if question be made touching the principality, and the radication of the soul, since there is only one soul in every Animal, not many, and one Animal hath only one soul and specifick form; we must hold there is one principal member, wherein it resides, as in its Castle: although it perform not all its actions therein, but act definitly and distinctly in the organs proper and ordained to every distinct action.

Now if you shal ask me which is this member, I do with the Peripateticks assign the principality to the Heart, and hold that the soul doth stick therein as in its root, from whence it is diffused into all the rest of the members. Yea and the holy Scriptures ascribe not only the radication of the Soul to the Heart, but certain other actions also which most men attribute unto the Brain. And indeed this is a very ancient opinion; *Plato* (saith *Scaliger* in his 1. Book *de Plantis*) learned these things of the wise men of *Egypt*, the Egyptians learn'd them of the Chaldæans, out of whose decrees all exact literature hath flowed. For the Chaldæans placed the Principles of all our motions in the Heart, as in their principle. *The Heart is the Principal part.*

Now that the Heart is the Part wherein the Soul adheres as in its root, and therefore the principal part, is many waies apparent. For that is the principal member, not wherein as in the immediate Instrument, the most noble action is exercised; but that whereon the actions of al parts whether ignoble or noble, do depend, and whereby they are governed. For the prime Agent is more noble than the secondary and Instrumental Agent. Hence that Argument of *Galen* is invalid, who thus concludes; that is the Principle, from whence the Nerves, Veins, and Arteries arise. For that member seems to be the fountain and seat of the faculty, from which the Instruments arise. But these three kind of Vessels have their original from three members; the Veins from the Liver, the Arteries from the Heart, the Nerves from the Brain. And therefore there are three chief members, and the most excellent is the Brain. For we must distinguish betwixt the prime and chief principle of any operation, and the instrumental or secondary principle. For that which is the immediate Principle of an action, is not alwaies the first and most excellent. The immediate principle of sense and motion is the Brain: but yet the soul is not rooted therein.

Nor is that Argument of greater moment, that when the Brain is hurt, the operations of the sensitive Soul are hurt; to which therefore for the same cause medicaments are applied. For the first Agent cannot act without Instruments. And therefore when they are hurt, the action is taken away. And therefore, though the Heart which is the immediate Agent be wel, if the Brain which is the immediate Agent be hurt, the action is abolished: after the same manner, the Hand being hurt, although the Brain be wel, a man cannot handle or hold a thing; because the immediate Instrument of handling is hurt.

That therefore must be held to be the principal member, which governs all the actions of the whol Body; which breeds the common and most familiar Instrument of the whol Soul, *viz.* the spirits, but that is the Heart: which besides other tokens, is manifest from swooning fits, in which sense and Motion, and all the actions in the body are taken away, through want of spirits which should flow from the heart.

Moreover, that is the principal Member, according to the unity or plurality whereof there comes to be one or more Animals. For because an Animal by means of one soul is one; by means of two, two; that member by the doubling whereof the Animal becomes double, must needs be held the seat of the Soul. Now that the Heart is such a member *Aristotle* tels us, *Lib.* 4. *de Gener. Animal. cap.* 4. and that truly. For experience doth teach us, that by multiplication not of the Brain but Heart, an Animal hath been made double. I wil produce some Instances collected by *Schenkius, observat. Med. P.* 1. *Obs.* 10. In a certain Town called *Emaus*, in the raign of the Emperor *Theodosius*, a Boy was born, who to the navel was perfect, but above he was divided into two, had two breasts, two Heads with their parts and Sences. For somtimes one part would eat, and the other would abstain, one would sleep, the other wake, somtimes they would play together, laugh and weep, and beat one another. Now they lived neer upon two years. Afterwards it fel out that when one of them died, the other that remained alive died by reason of the putrefaction communicated from the other. Again, in the yeer 1531. there was one born, and grew to the stature of

of a perfect man, who had only two Heads and two Shoulders, so that one Head stood behind the other, and they were wonderfully like in favor, their Eyes and Beards were alike. They had the same appetite to meat, were hungry at the same time, had the same voyce, and both Heads had the same desire to the Wife which he had, and to evacuations. From which Stories it is apparent, that in the first who had a double Heart, all the Animal actions were doubled, but in the other, though there were two Heads, yet the actions were single, and that therefore the Principality belongs to the Heart. For if Sense, Motion, and other animal actions depend primarily on the Brain, and not on the Heart, why were those actions double only in the former, in whom besides the Brain there were two hearts; and not in the latter, in whom there were only two Heads?

Chap. 2. *Of the vegetative Soul.*

HAving spoken thus much of the Soul in general, it remains now that we treat of the sorts of Souls. And because the vegetative Soul is common to all living Creatures, we will begin with the consideration thereof. Now the vegetative Soul is the act or perfection of an organick body, whereby it lives, is nourished, encreases, and begets it like. There are belonging to this Soul three faculties: the nourishing, growing, and ingendring faculty. The nourishing faculty tends to preserve the Individual or particular living thing; the growing faculty tends to encrease the Quantity thereof; the Generative preserves the kind or sort. For the nutritive or nourishing faculty is that which turns the food into the substance of the living Body. For since the parts of a living Body are consumed by the native heat, (left if there should be a continued resolution, the Creature should perish) the nourishing faculty was bestowed thereupon, to repair that which is consumed. Now this Interchange of resolution and nutrition, lasts as long as the life: *for a living Creature is nourished as long it lives.* Aristot. 1. *de Gen. et Corrup. cap.* 5. *t.* 41.

The definition of the vegetative soul

The three faculties thereof.

The nutritive faculty.

Now to Nutrition three things are necessary, as *Aristotle* teaches 2. *de Anim. cap.* 4. *t.* 49. *The thing nourished, that wherewith it is nourished, and that which doth nourish: now that which nourishes is primarily the Soul, that which is nourished is the Body which contains it; that wherewith it is nourished, is the food.* Now *Zabarella* hath thus expressed the whol nature of nutrition, in *Lib. de Accret & nutrit. cap. ult.* Nutrition is the aggeneration of matter to the parts in a living Body, caused by the vegetative soul through help of natural heat, out of the food which is taken in; that the matter which is steamed away may be restored, and that the living Creature may be preserved, to the end of the term appointed by nature. *Scaliger* thus briefly defines it: Nutrition is a natural union of the changed food.

Four faculties subservient to the nutritive.

The Principal faculties have other faculties subservient to them, which yet do not arise from the Principal. For one faculty doth not possess another: but they al depend upon, and proceed immediately from the Soul. The nutritive faculty hath four faculties subservient thereunto; the Attractive, Retentive, Concoctive, and Expulsive: others add the Separative, which severs things hurtful. The Attractive, is that which draws the food; the Retentive is that which retains it, til it be duly elaborated; the Concoctive, is that which alters it and makes it fit for the living Body: the Expulsive, is that which drives out superfluous matter, which is unfit for nourishment.

The Augmentative faculty.

The definition of augmentation.

Now in the first age, not only nutrition is made, but also augmentation, and the parts which are added to the living Creature are greater than those that are consumed by the natural heat. Now Augmentation or Growth, according to the definition of *Zabarella de accret. & nutrit. cap.* 25. is the motion of a living Body, whereby the whol Body and al the parts are at once extended according to al dimensions, so as to gain a greater quantity; caused by the Vegetative Soul through assistance of the natural heat from the food taken in, and converted into parts of the substaunce of the Body, greater than what hath been consumed; that the living Creature may attain to that greatness which it ought to have, that it may perform al the operations of Life. For Accretion or Growth differs not from Nutrition in the subiect thereof, matter out of which it is made, and the Efficient Cause. For the same subject is the living Body; the Matter out of which, the Food; the Efficient, the Soul: but they differ in their form and End.

For Nutrition is the ag-generation of aliment, and belongs rather to Generation than Motion: but the form of Growth is a motion of extension, to a greater Quantity of the whol Body

body and all its parts. The End also is different: For in Nutrition there is only the restauration of what is consumed; in growth there is an acquisition of more than is consumed. Hence *Aristotle*, 1. *de Generat. & cor. cap.* 5. *text.* 14. *Nutrition is the same thing with Accretion or Growth; but they differ respectively: For inasmuch as that which is joyned to the Body, is potentially so much flesh, it is able to encrease the body: but inasmuch as it is potentially bare flesh, so far it is able to nourish.*

The Conditions of Augmentation.

Now because there are many Augmentations improperly so called, it is worth our labor to observe out of *Aristotle*, *Lib.* 1. *de Generat. & corrupt. cap.* 5. *t.* 33. three conditions of Accretion or Growth properly so called, or three things necessary to Accretion. 1. *Not only the whol Body must become greater, but also every part thereof.* 2. *It ought to become greater, by means of some matter coming from without.* 3. *That which is augmented must continue the same thing in number which it was before.* In the first condition is explained the proper nature of Accretion. For though some doubt (since many mutations concur in Accretion, and not only the addition of Aliment, but also extension is necessary) in what mutation the nature thereof should consist: yet their Opinion is the truer, which joyn both these mutations together, and hold that Accretion or Growth consists both in the conversion of the matter of the Aliment into the substance of the living Creature, and also in the extension of the said Creature. For Growth is caused by somwhat coming to the body, and the thing grown hath changed its place, 1. *de Gener. & Cor. cap.* 5. *text.* 25.

Now, after what manner a greater quantity is acquired in a living Creature, Authors are also at variance; Some conceive it is done by driving, and that one part drives another, and another another, after the same manner as we see it is in the Nails and Hairs: But this is not agreeable to truth. They think more rightly, who beleeve that it is done by extension, viz. When the Aliment is extended through all the parts of the body, and through all the different postures of the said parts; which comes to pass when all the Pores are filled, which being full, the parts are extended: and all the parts being extended and augmented, the whol body is also encreased; after the same manner as we see a spunge grow great, after the water hath insinuated it self into all the parts thereof. Now according to the extension of the Body, the soul is also extended: and if any man will call it being so extended, greater, let him remember, that a Form of it self is neither great nor little. Hence *Scaliger*, Exercit. 101. Sect. 15. *The Form when it extends it self into the newly applied matter, it advances it self, but is not encreased: For it does not generate a new Form. And verily he that shall call a Form greater or lesser, will abuse the patience of wise men.*

Now living Creatures are not alwaies augmented, but only to a certain term of their age; the cause whereof is not in the soul: For neither it, nor its Faculties, which are proper to its Essence, are corrupted or weakened, but only the body. Nor is the cause in the natural heat; for that is as strong in a yong man, as in a boy. But the impediment is in the body; viz. the bones, which are the chief part that is augmented, and according to the encrease whereof the whol body is encreased, are more moist and soft in youth, and more apt to be extended; but in succeeding Ages they are so dried and hardened by the natural heat, that they become unapt to be extended. Although in some elderly persons the flesh and fat are many times augmented, yet that is no true growth, because the whol body is not augmented, but only the softer parts.

The generative faculty.

The definition of generation.

Finally, The generative Faculty is that which by the prolifick seed begets its like: And the Generation of a living Creature, as *Aristotle* defines it, *de Vita et Morte, cap.* 10. *Is the first participation of the Vegetative Soul with heat.* For living Creatures are said to beget their like, when they give out somwhat of their own matter, and their own form; which is then done when they yield their seed. *For in the seed there is both the matter and form of a Dog forth coming: Nor does the seed of a Dog differ from a Dog, otherwise than as aptitude from Act; and there is nothing added to the seed, but an expression of those Organs which were before confused,* saies *Scaliger* in Exercit. 268. and Exercit. 6. Sect. 5. and 7. *The form is in the Dogs seed, in the aptitude whereof it is said to be; because the seed is able and apt to give that form which it contains in it self; or because it wants the express Instruments, which afterward the Soul frames to it self, both by altering the whol, and disposing the parts, and is its self the builder of its own house.* And in the same Exercit. Sect. 10. *Therefore a Tree generates when it produces its seed. But a Tree is not then generated, when it sprouts up out of the seed; but then the generated Tree, which was before imperfect, becomes perfect. So a Dog does not ingender when the whelp is brought forth, but when he ingenders seed: Because in the very act of copulation many have died, before the*

the seed received any disposition or qualification in the Womb. Which we see more evidently in Plants: For the Almond Tree being dead, a planted Almond taken therefrom grows up to a Tree. Now the Soul engenders a Soul by promotion of it self; after the same manner truly, as in growing it insinuates it self into the new matter of the nourishment.

Now Living Creatures obtained this Faculty of propagating their kind, from their first Creation by God, when he blessed all living Creatures, saying, *Encrease and multiply*; and again, *Let the Earth bring forth Grass, the Herb yielding seed, and the fruit Tree yielding fruit, whose seed is in it self, upon the Earth*: and again, *Let the Waters bring forth abundantly the moving creature that hath life, and fowl that may fly above the Earth in the open Firmament of Heaven*: and again, *Let the Earth bring forth the Living Creature after his kind, Cattle, and creeping things, and the Beasts of the Earth after their kind.*

Howbeit the manner of the Propagation of living things is various. In Plants indeed if a branch of Willow be pluckt from the Tree, the Soul is divided by division of the matter, and abides in the branch; and therefore from the said branch stuck into the Earth, a Tree of the same sort will grow up. The same is done in other Plants by their Roots, in others by their seeds, and in others after other manners propagation is caused; as may be seen in the Writers of Husbandry. In all which nevertheless it is necessary, that the matter taken away may afford a fitting Mansion for the soul; which every part in all Plants cannot afford. For examples sake, A Willow is propagated by a bough stuck in the Earth; but a Pear-tree cannot be propagated after the same manner.

But in Animals or living creatures, although the manner of Propagation may also seem to be various, whiles some produce Egs, others living creatures: yet herein they seem al to agree, in that Animals do not generate by any part of their body pluckt off as Plants, but by seed, or somwhat which answers to seed.

For the seed which *Epicurus* (as *Plutarch* relates, *de placit. Philos. Lib.* 5. *cap.* 3.) called *an Abstract of the Soul and Body*, being cut off from the rest of the body, according to the division of the subject, the Soul is also divided, and some portion thereof is with the seed separated from the Animal; which being of the same species with the Soul from whence it is taken, is now become numerically different, in regard of the subject. Out of the seed, by reason of this soul, a new Animal arises, while the soul lying hid in the seed, rouses it self, and displaies its Faculties, and by operating manifests it self; and making use of the innate heat and spirits, it begins to shape al things necessary to the constitution of an Animal or livnig creature, and distinguishes, disposes, orders forms, and fashions the subject matter; that so it may have a perfect and fitting house, like to that from whence it came, and that it may have Instruments in a readiness, whereby it may put forth al its Faculties, and exercise al its natural Actions; which house it afterward possesses, after the same manner as it insinuates it self into the new matter of Aliment, when the Creature grows.

Howbeit, there is betwixt Plants and Animals, especially the more perfect sort, this difference; That Plants which breed seed, breed it so qualified, that it alone suffices to the production of a like Plant: but in the more perfect Animals which have Sex, the seed of neither Parent is sufficient to beget their like; but as *Plato* hath it, Each Sex contributes its shot to the matter of Generations; and the seed of neither Sex taken alone, but of both joyned together, and united in the Womb of the Female, is prolifick and fruitful seed.

Chap. 3. *Of the Parts of Plants.*

SInce therefore there are three manners of Life, and Plants live, are nourished, grow, and generate; Bruits have besides, the use of sense and local motion; and a Man besides all these, hath the use of Reason: having spoke of the Vegetative Soul, before we shall speak of the Sensitive and Rational Soul, we must first treat of Plants. *Now a Plant* (which the Greeks call *Phuton*) *is a Body animated and vegetative, or endowed with a nutritive and generative faculty.* Where I must in the first place acquaint you with this, of which mention was made before, viz. How that many are of opinion, that all sorts of Plants have no other Faculty but the Vegetative, which is common to the whol kind, but that only the same kind is restrained by certain bounds to the proper faculty of its own sort. But this is a false Opinion: For if the case were so, there should be indeed no specifical difference

The definition of a plant.

ference in Plants and Animals; nor should a Rose differ from an Oak, nor a Mouse from a Lyon, except in some Accidents. But thus we are to hold; That the Vegetative Soul alone does not constitute any sort of Plants; nor does the sensitive Soul constitute any sort of bruits, but only an Animal or Living creature, which is the kind comprehending Man and Beast: but the sorts of Plants and Animals do differ by their specifick forms; as namely a Rose from an Oak, a Fir-tree from a Violet, a Dog from a Wolf, and a Wolf from a Lion and a Man. And from the difference of forms proceeds this diversity of Actions, so that among Living Creatures some are more ingenious than others. And in vain it is that some anxiously dispute, Whether some Animals besides Man, are not Rational? For those actions we see in some Animals which are more ingenious than others, do not proceed from a Rational Soul, which is proper only to Man; but from the Soul that is proper to that sort of Animal. For as a Rose hath one soul, a Poplar another, and therefore the Rose and the Poplar have different operations: even so, as there is one soul of a Sheep, another of a Sow, another of a Dog, another of a Fox, another of a Lyon, another of an Elephant; so also all these sorts of Living Creatures do differ both in the structures of their bodies, and in their specifical actions. And although in some sorts of Animals actions appear sufficiently wonderful; yet the soul of Man hath only gained a proper name, and is termed Rational: the rest are for the most part destitute of proper appellations. But that we may speak now of Plants; every Plant consists of a proper soul, and of a body convenient to its sort.

whether som bruits are rational?

We have already spoken of the Soul, it remains that we should speak of the Body. But first there is a Question that presents it self: Whether the two Sexes are in Plants? To it *Scaliger* answers, in 1. *de Plantis*: There are in Plants (quoth he) the principles of Male and Female confounded, and that by an excellent design of Nature. For since Generation is made by an agent in a Patient; Nature hath put into her work, to which she had denied Motion and granted Generation, proportionable generative faculties joyned together, which may be also hence collected: Because in some Plants it is seen, that of one seed the male, of another the Female does spring up. Which is apparent in Hemp; Out of the same trunk proceeds seed, which partly grows to be Male, and partly Female.

whether there are two Sexes in Plants?

Now some parts of Plants are necessary to the constitution of the whol Body; others are superfluous. There are some hard Excrements, as Mushroms, and Puck-fists; some soft, as tears; and of these, some remain liquid; others grow hard, as Gums.

The Excrements of Plants.

Among the parts necessary to the constitution of the body, besides that same juyce diffused through the substance of the whol body, wherewith Plants are nourished, and which answers to the blood in Animals, the most simple are, Fibres, Nerves, and Flesh. Fibres, which the Greeks call *Ines* (which *Scaliger*, *de Plantis*, would rather call threds or hairs; because the lobes and little roots of the Liver are called *Fibræ*) are those long, continued, stretched out parts, running through the whol Plant, answering to Veins, Arteries, Nerves, and Fibres in Animals; the greater and more succulent whereof are called Veins and Ribs, but the thinner and drier are called Nerves: And they are made both for the nourishments distribution into all parts of the Plant, and also for their firmness and consistency. The flesh is the remaining substance of the Plant, answering to musculous flesh in Animals. Now the flesh is of three kinds; some is moist, such as is in Cherries, Prunes, and such like fruit; some is a little more solid, such as is the pulp of a Pear and an Apple; some is of a more compact and woody substance as it were.

Their simple parts.

Fibres and Nerves.

Flesh.

Of these are made others, which themselves also are numbred amongst the simple and similar parts; viz. The Wood, the Marrow, and the Bark. The Wood in Plants called *Lignum*, is a body hard, that wil cleave, and consists of thin fibres: the middle part in the Wood is called the Marrow, Pith, or Heart: The Coat wove together of Fibres, going about the wood is termed *Cortex*, the bark; which when 'tis very thin, 'tis by a special name called *Cutis*, the Skin or Rind, especially in Fruits, whose flesh is alwaies covered with skin: that which is thicker is called by the general term *Bark*. Howbeit the Bark it self is not simple; but in most Plants there is an outer, and an inner: The inner is called *Liber*.

Wood.

Marrow.

Bark.

As to the compound parts of Plants, some are constant, others mutable. The constant are, the Root, the Stock, the Bough, the Branch: The mutable are, the Leaves in most, the Flowers, the Fruits. The Root is the lowest part of a Plant, whose Office is, not only to fasten the Plant and support it in the Earth, but also to draw its nourishment; and therefore it's compared to the Mouth in living creatures; yea, and by some the concoction of the Aliment drawn out of the Earth is ascribed to the Roots.

the Compound parts. 1 Root.

the stock, stalk, trunk Branches, Boughs, twigs. Suckers.

The Stock, Stalk, or Trunk of a Plant, is that part which riſes immediately from the Root. Which is indeed ſoft in Herbs, and is termed the ſtalk; but in Trees and woody ſhrubs 'tis hard, and termed *Caudex* the ſtock. The ſtalk and ſtock parts into branches, and the part where the branch iſſues is properly called a knot; the branches are divided into boughs and twigs; beſides theſe there are ſuckers, or ſmal twigs that grow up out of the Root.

Leaves, Flowers, Fruit.

Out of the boughs and twigs ſpring the Leaves, Flowers, and Fruits; and in ſome Plants tendrels, fingers, or claſpers, by help whereof they rear and ſuſtain themſelves againſt ſome wall, pale, tree, &c. Parts of the Leaves are the little ſtalks they grow by, yet ſome Plants have them not, as the Indian Fig-tree.

Flowers.

The Flowers to Plants are as the child in the womb, which come to perfection in the ſeed and fruit, or they are rather the firſt covering of the fruit. Now the Flowers conſiſt of a moſt thin exhalation and a ſubtil ſpirit, which breaks forth when any Plant does grow wanton and big with deſire of generation. For there is no emiſſion of ſeed without ſuch a ſpirit, nor any propagation of the ſoul, in Plants nor in Animals. Now the Flower includes within it ſelf, and defends the fruit when it firſt breaks forth, till it becomes more firm and able to bear the injuries of the Air. For then the ſpirit ceaſing and failing, which breaks out with the fruit, and in the act of Generation, the flower falls off. Howbeit all Plants do not bloſſom, nor do all that bloſſom bear fruit. Now the flowers are compounded of divers parts: For they conſiſt of very thin Leaves, ſeverally colored, ſhaped, and ranked in ſeveral Plants. Then is the Cup wherein the little Leaves are planted as in their baſis, and wherein they are ſhut as in a caſe. There are alſo threds or hairs, ſuch as the yellow in Lillies and Roſes; finally, there are the ſmal ſtalks by which the flowers hang.

the Cup.

Fruit.

Finally, there is the Fruit, by which word we ſometimes underſtand the ſeed; ſometimes beſide the ſeed, the fleſh with the ſeed is after a ſpecial manner termed Fruit. For the ſeed is either contained in Cods, as that of beans and peaſe; or in Caſes; or in the pulp of the fruit, as in prunes, pears, cherries. Now the Greeks term that ſame fleſh or ſubſtance which compaſſes the ſeed, *Pericarpium*. And of theſe parts do Plants conſiſt, and ſome have all theſe parts, others not. And ſome have only one of them, others more. The whol ſubſtance of a Puckfiſt is well near all Root. Contrarywiſe ſome have no Root, as Miſſelco which is ſuſtained and nouriſhed by the Root of another Plant. Alſo Toad-ſtools have commonly no Root. A Ruſh hath no branches; Dodder no Leaves; the Fig-tree no flower; the Orice flower no fruit; Maiden-hair neither flower nor fruit.

Beſides theſe parts, ſome Plants alſo have others, which grow out of an excrementious humor. Such is the moſs of old Trees, the little ſpunges on Dogs-bryar, and other excreſcences on other Trees.

Chap. 4. *Of the Differences of Plants.*

the diviſion of Plants.

NOW Plants are divided into four kinds: *Dendron*, a Tree; *Thamnos* a Shrub; *Phruganon* a Buſh, (which *Gaza* calls *Suffrutex*, though *Scaliger* like not that word, *Exercit.* 139.) and *Botane* an Herb. Now how theſe kinds differ, is not ſo manifeſt. They are commonly diſtinguiſhed by their Trunk, and their continuance: but *Scaliger* likes not this kind of Diviſion, *Exercit.* 389. For alſo Harts-tongue laſts all the year without any Trunk. And Lettice and Coleworts have a kind of trunk, which are Herbs. He therfore both *in the place alleadged, and in his* 1. *de Plantis*, thus diſtinguiſhes them: An Herb ſends from the Root Leaves, beſides thoſe two common to all, which preſently iſſue out of the pulp of the ſeed changed; and in proceſs of time a ſtalk, though ſome never have any. But in a Tree and buſhy ſhrub theſe Leaves do not firſt come forth, but in the firſt place a ſtalk, and that one, or many; if one, either it is a great one, and that is a Tree; or a little one, and that is a ſhrub; or if many, then it is a buſh: and it is the property of a Tree not to die and come up again; but ſhrubs and buſhes do ſome continue as trees, and others die and come up again, as Herbs. Thus then a tree and a ſhrub agree, That each hath a ſingle trunk. But they differ in greatneſs, and ſometimes in yearly dying. A buſh differs from a tree in ſmalneſs, and therein it agrees with a ſhrub; but it differs from both in the multiplicity of its ſtems or trunks. There is no need it ſhould laſt all the yeer, no more than that a ſhrub ſhould. An Herb agrees with a ſhrub in the ſingle-

neſs

nefs of its ſtem, as the Colewort; ſomtimes with a buſh, in the multitude of its ſtems, as Fennel; ſomtimes with neither, by having no ſtalk.

But *Scaliger* ſeems not to have perfectly explained the whol Buſineſs; and eſpecially there is a doubt concerning the Shrub, which he will have to be ſingle ſtemmed, becauſe he held that the ſhrub had but a ſingle ſtem: whereas others attribute a manifold ſtem to the ſhrub, and they ſay that is a ſhrub which amongſt wooden Plants is of ſmalleſt height and thickneſs, ſuch as Rue, Sage, Hyſop, Marſh-mallows.

In ſearching out the Univerſal Nature of Plants, we muſt diligently enquire into their differences: which are indeed very many, ſo that it is hard to omit nothing, and in the mean while, not to produce things unprofitable and ſuperfluous. Now theſe differences are taken from their Original, Native place, internal form, external figure and matter. Now ſince the internal forms lie hid, nor are known to the ſenſe, they muſt be known from the vertues and qualities which proceed from them.

And firſt from the manner of propagation, which is manifold. For, firſt of all, ſome Plants ſpring of their own accord, in ſuch places as are far from the reſort of men, and are not capable of tillage. For the Earth hath in it the hidden ſeeds of Plants, from the beginning of the world, inſerted thereinto by the Divine Benediction, and ſhe ſends them forth out of her boſom; or ſhe receives ſeeds brought from elſewhere by Winds and Rains, and other means, and cheriſhes them in her lap; which manner notwithſtanding does appertain to that which follows. For in the ſecond place, ſome Plants ſpring from others. For firſt ſome Plants are propagated by ſeed; ſome by roots, bulbs, boughs and branches, and ſome are propagated by one of theſe, others by more: ſome ſpring from ſeed alone, as Smallage, Marjoram, Henbane; others hardly or never of ſeed, as the Fig-tree; others late, as the Peony; others of a Root alone, as the Hop, and Acorus; others of ſeed and branches, as the Roſemary. And the way of propagation by branches is again threefold; For either the branch or bough plucked off, is ſimply ſtuck in the Earth; and ſo the Willow and Roſemary are propagated; or the branch is inſerted into another trunk, which is called Grafting; or when the Suckers which ariſe from the Root are pulled away. Or when a branch neer the Root hath its lower half covered with Earth, the upper part remaining free. For then that branch ſends out Roots into the Earth: which being done, a yeer or two after that branch is cut off from the Tree, and becomes a peculiar Plant: or of one Plant many are made. So the Dreſſers of Vineyards are wont to wean their Vines.

Moreover, Some Plants grow in moiſt places, others in dry. Thoſe which grow in moiſt places, grow either in the water it ſelf, or near the water, as on the banks, or upon Walls and Rocks, and other places, which are moiſtened by the appulſe, or ſprinkling, or vapor of the waters, as Liver-wort and Maiden-hair. Thoſe which grow in the waters, grow either on the top, as Duck-weed, or from Roots. Alſo ſome never mount above the water, as the kinds of *Alga*, Sea-weed, or Ore-wood; others ſpring above the water, as *Aquapium*. Again, ſome grow in Brooks, others in Fountains, others in Ponds, Pools, and Lakes; ſome grow in the Sea, others in other places where water hath been, but now is not, as *Xanthium*, or Ditch-bur. Again, Land Plants do grow ſome on Mountains, Hills, Rocks, Walls, Houſe-ſides, upon hedges, in fields, meadows, Vineyards, Woods: others in plain places, earthy, gravelly, ſandy, or clayiſh.

To the Native place alſo belongs this conſideration, that ſome Plants are inſtead of ground to others which grow upon them, as to Moſs and Miſſelto which grows upon the Oak, the Holm, the Pear-tree, the Hazel, the Linden, the Birch, the Apple-tree, the Plum-tree, the Fir, the Pine, the Elder, and Cheſtnut-tree.

Moſt indeed of the Ancients were of Opinion, That the Thruſh having eaten Miſſelto-berries, the pulp being digeſted, the ſeed was caſt out with the dung, and falling upon ſuch Trees as the Thruſh uſed to ſit upon, from that a new Plant of Miſſelto ſprung upon the ſaid trees. But this conceit is not agreeable to Reaſon: For it is not probable, that the ſeed can ſo cleave the barks and pierce into the hard wood of a tree. And why ſhould it not grow upon many more trees on which thoſe birds neſtle, as wel as on the foreſaid? Nor hath there ever any ſeed been found in the maws of Thruſhes that have fed upon Miſſelto-berries. Moſt likely therefore it is, That Miſſelto is like the horns which ſpring out of the bones of Animals, and that the principles of Miſſelto, in a juyce Natural thereunto, being cheriſhed by the internal heat, and aſſiſted by the heat external, do grow together into this Plant.

Moreover, ſome Plants grow moſt ſpeedily and attain their perfection, others very

ſlowly; ſo that this difference is manifeſt in the Alder, Willow, Peach, Pitch-tree, and Oak.

Again, ſome laſt all the yeer, as Trees and Capillary Herbs; ſome continue not. And of theſe ſome die and grow no more, as Wheat, Barley; others grow again, as Gentian. And of theſe ſome laſt all the yeer, as Agrimony; and ſome periſh within the compaſs of a yeer in ſeveral manners. For ſome laſt one month, others three months; ſome two years, others three, and others four. Again, ſome are perpetually green, as the Fir, the Box; in others their Leaves fall off, and grow again.

Moreover, ſome are fruitful, others barren; ſome bear flowers only, others both flowers and fruit; and ſome only once in their life, others often; and that either yearly, or every other year: and ſome flower in their firſt year; others in the ſecond, third, and ſome not till their fourth yeer.

Alſo in their figure and other qualities partly ariſing from their forms, there is a great diverſity. For ſome are ſtraight, others crooked, round, cornered, Turbant-faſhioned, hollow, ſolid, prickly, without any knot. They differ in ſubſtance, which is ſpungy, compact, ſoft, hard, thick, thin, fat, clammy. Some are temperate, others hot, cold, moiſt, dry; ſome are ſmooth, others rough, thorny, hairy, downy. The taſt of ſome is ſweet, of others bitter, biting, ſalt, harſh, ſowr; others are void of taſt. Alſo ſome Plants have taſt in al their parts, others in ſome only. Some have no ſmel, others have a ſtrong ſmel, others a ſweet; ſome a vehement ſmel, others a weak; ſome ſmel totally, others only in ſome part.

There is no leſs variety in their colors. For though al Plants are green; yet ſome are more, others leſs green; ſome are of a light, others of a deep green; in ſome there is a whitiſh greenneſs, in others a yellowiſh, in ſome a reddiſh; ſome are ſpotted, and others have no ſpots.

Moreover, there is a great difference of Plants in reſpect of the parts whereof they conſiſt. For the juyce wherewith they are nouriſhed, and which anſwers to the blood in Living creatures, repreſents water in ſome, milk in others, as in Spurge; in ſome it hath a Saffron dye, as in great Celandine; in others it repreſents Oyl: and therefore it differs much in color and taſt. Alſo ſome juyce is wholſom, another purging, another venemous.

Again, The Fibres in ſome Plants are ſtreight, in others oblique, ſmal, thick, ſoft, hard. The fleſh is in ſome thick, compact; in others ſpungy, taſtful, taſtleſs; alſo it is of different ſmel and color in different Plants. The Bark is fleſhy, nervous, clammy, in color, taſt, ſmel, much different: And the ſame differences we find in the Wood. The Matrix or Marrow, is in ſome ſolid, in others ſpungy.

Alſo there is a great difference of the Roots of Plants. You have a Root great, ſmal, long, ſhort, continued, cut off; round like a Globe; ſingle and manifold; fibrous; collected, ſpreading; deep, ſhallow; thick, thin; ſoft, hard; ſtiff, limber; criſped, even; ſtreight, bending; compact, ſpungy; fleſhy, barkiſh, woody; round, turbant faſhioned; ſingle, double; hairy, ſmooth; rough, glib; moſſie, juycie, dry; conſiſting of ſcales, uniform; crumbly, ſoluble, boylable, eſculent; heavy, light; white, yellowiſh, red, black; ſweet ſmelling, ſtinking; bitter, ſweet. A great Root bears a great Plant; a little Root, a little Plant; a great Root bears a ſmal Plant, as in a Turnep; a little Root a great Plant, as in a Pine-tree: as *Jul. Cæſar Scaliger* hath collected, and digeſted theſe differences, in 1. *de Plantis.*

The ſtems do ariſe ſome before the Leaves, others with the Leaves, in ſome they are perpetual, in others annual; in ſome ſtreight, crooked, trailing on the ground, growing upright, thick, thin, ſolid, hollow, knotty, without knots, woody, herby, round, four ſquare, three cornered, nervous, ſtreaked, ſmooth, rough.

The variety of Leaves is thus digeſted by *Jul. Cæſ. Scaliger*, in 1. *de Plantis.* In reſpect of ſhape: there are round Leaves, as in Penny-wort, or Two-penny graſs; almoſt round, as in Bindweed, ſmal Celandine, Aſarabacca; oblong in Hyſop; plain in the greateſt part of Plants; round and long in Stone-crop; with a continued edg in the Birthworts; with a creſted edg in the Lawrel; a Saw-faſhioned edg in the Elm; blunt teeth in Scordium; large toothed in the two Cichories; ful of bendings in the third kind of Cichory, which they call Monks-head; forked in the *Caucalis* or baſtard Parſley; fingered in Ellebore and Woolfs-bane, lobed in Fern, hair-like in Fennel. In reſpect of their Surface, they are rough, biting, ſharp-pointed, in Borrage, Nettles, Artichoaks; they are prickly either by reaſon of their kind, and that continually, as the Bur-Thiſtle; or by age in a kind, as the

Sow-

Sow-Thiſtle. Some have for Leaves real Thorns, as the *Corruda* or wild Aſparagus; ſome as it were Thorns or Prickles, as the Juniper. Many have thin leave, Purſlane have thick. The Leaves of moſt Plants hang on by a ſmal ſtalk, which is ſtreight or crooked, long or ſhort. Some have no ſtalks, as the Lilly. Alſo from the places of the Plant; from the root, from the ſtem, from the branches; on the top; on the bottom. The Flower-de-luce hath ſharp-pointed Leavs, moſt Plants have them blunt. In reſpect of Quantity: they are great, little, broad, narrow; ſingle, manifold, In point of relation and ſcituation, ſome grow thick and cloſe together, ſome grow thin and far aſunder. In reſpect of colour; they are al in a manner green, but with a various greenneſs; ſome few are pale-green, as a ſort of Orach; ſome red as another ſort of Orach and Beets. Alſo ſome naturally die by ſickneſs in the Autumn, as the Bramble, the Vine, the Apple-tree. In point of ſcituation; ſome ſtand bolt upright, others hang down, ſome are ſaddle-ſhap'd, crooked, criſped, rouled together, hollowed as the Lettuce; ſtreaked, nerved, veined, with bending Gutters. And what hath been omitted in the former differences; as the ſoft, hard, leatheriſh, limber, brittle, ſhining, dul, woolly, hairy, ſmelling ſweet, acid, bitter, ſalt, ſweet, harſh, taſtleſs, continued, with holes bored through, or holes as it were, as in St. Johns-wort. Alſo the diſpoſitions of trembling, of falling, of abiding, and turning according to the Sun. Alſo of order; ſome are ſet in a confuſed manner, others are orderly placed; ſome alternatively do cloath the branch at equal diſtances, ſome are ſet juſt one againſt another, whether they be two, three, or four, compaſſing the branch like a Crown. Some breed one Leaf upon another.

Flowers do ſome of them come out before the Leaves, as in the Peach; others after the Leaves; ſome come out the firſt year with the Plants, others the ſecond or third yeer, and ſome later. Alſo in reſpect of the time of the yeer, there is great variety. For ſome flower in the Winter, as black Hellebore; ſome at the beginning, others at the end of the Spring, ſome in the Summer: and ſome flower once a yeer, others twice, others thrice. Alſo the ſcituation and place from whence Flowers grow, is not the ſame: for the moſt part, they grow out of the ſtock, the branch or twigs; yet ſomtimes from the Roots. And ſome flowers ſtick on the ſmal ſtalks, and thoſe either long or ſhort; Some come out of one Cup, others out of divers Cups; ſome come out like cluſters of Grapes, others like ears of Corn, others in a round tuft, on ſome there are more flowers, on others fewer, and ſome of them have many, ſome few leaves. Some Flowers are fertile, others barren, and theſe do ſome of them compaſs the fruit, others are ſeated therein. Alſo there is a great difference in the falling off of the Flowers, ſome fall off more ſlowly, others go away in Down, ſome are contracted, others dried.

The ſame variety is in the colors, odors, taſt, and ſhape, al which can ſcarce be perfectly ſet down.

Finally, The ſame variety is to be ſeen in the Seeds, and Fruits. For ſome Plants bear fruit, others not, as Harts-tongue. Of thoſe which bear fruit, ſome bear much, others little; ſome once every year, ſome twice, others thrice; again ſome bear fruit only once in three yeers. Some bear fruit early, others late; the Mulberry Tree flowers late, its fruit comes ſuddenly to perfection; contrariwiſe the Peach-Tree ſoon flowers, but is long ere it bear fruit. Again ſome flower late, and bring forth late fruit. Some have fruit and no flower, as the Fig-Tree; ſome have flowers without fruit, as the Flower-de-luce; but for the moſt part the fruits come out of the flowers. Some have fruit of only one kind, others of divers kinds, as the Oak. Some produce fruit from their root and ſtem, ſome at their boughs, others on the boughs under the leaves, on the leaves, above the leaves; and the fruit ſticks upright, or dangles, or ſticks faſt, or ſits, or cleaves, with a ſtalk, without a ſtalk, ſingle, double, one, divers, thick together, here and there, far aſunder, rare.

The Seeds grow, ſome of them naked, others are ſhut up in ſome other ſubſtance. And ſome are contained in ſome humor, others in a ſhel or bone, others in an hollow bag, and ſomtimes in one fruit one ſeed, and ſomtimes many, either ranked in order, or without order. There is no leſs diverſity in their figures; ſome are round, others oblong, ſome repreſent one thing, ſome another. In the bags or cods wherein the ſeeds are contained there is the like Variety. For ſome of the Cods may be eaten, but the grain not, as the Ceratia or Careb fruit. Of ſome the pulp only is eſculent, as the Caſſia: ſome cods are not at al eſculent, as of Bean, Lupines, horned Poppy; ſome boyled are all eaten cod and fruit, as french Beans: of ſome only the Surface is eaten, the skin being left, as of Peaſe and the Pigeons-Vetch. Alſo from the figure there is much difference: alſo from the ſubſtance of the Grains, their magnitude, figure, number, marrow, bark, color, ſcituation. *Scaliger* in 1.

de

de Plantis. In fruits also, the Rind wherewith they are covered, is thin or thick, hard, boney, woody, smooth, rough; and al fruits are covered with flesh, skin, or shel. And with it they are either totally covered, or half covered, and that not after one manner. For an Acorn is covered in one manner, an Hazel Nut after another manner. Also there is great diversity of tast in fruits; yea and in one part there is one fruit, in another another. Also some fruits may be eaten, others not; and in some that which is to be eaten is within, as in Almonds; in others both the kernel may be eaten, and the pulp which doth compass the same.

Now to illustrate these differences of Plants with examples would be too tedious. This as it hath been done by others; so *Andreas Matthiolus* a most learned Herbalist, *in his Preface upon* Dioscorides, hath both collected all this variety, and shewed how Plants differ in their native place, their roots, stalks, flowers, seeds, and fruits.

Chap. 5. *Concerning the History of Plants.*

FOrasmuch as that which *Jul. Cæs. Scaliger* writes *in his Exercit. 104. sect. 6. To collect out of Books such things as have been delivered by the ancients is very dangerous: the true knowledg of things is learnt of the things themselves*; is both true in other things and most true in the Doctrine of Plants: they that would gain the knowledg of Plants must of necessity know the Plants themselves. And although in this Age of ours, the Art of Printing hath afforded great helps to this Intent; seeing not only the History of Plants hath been described and published by many, but also the Plants have been delineated, and painted out with elegant pictures, by many learned men, especially *Tragus*, *Matthiolus*, *Fuchsius*, *Dalechampius*, *Pena*, *Lobelius*, *Dodonæus*, *Clusius*, *Taberno-montanus*, *Bauhinus* and others; by which it is much easier to know the Plants than by their descriptions alone: nevertheless Plants are best of all known by view of the Eye-sight.

And seeing in this place it is impossible, by way of compendium to reckon up al plants, much more impossible to describe the same; and that yet it is very profitable to the knowledg of Plants, to have the knowledg of certain general heads, to which al Plants may be reduced; I have thought good in this place to propound certain Tribes, and a method as it were of Herbarisme, with the names of the principal, and the virtues of such as are most in use. For though I know some have been extreamly sollicitous, laboring to reduce all to Dichotomies: yet how unhappily they have acquit themselves therein, the succes doth shew. And therfore I have chose herein rather to imitate *Lobel* and others, who have distributed some Plants at least into certain Tribes. It wil be easie for any man to fetch the petty divisions and enumerations from the foresaid Authors, and there to see their Pictures and Descriptions. Only this I shal hint by the way, that many are indeed superstitious in reckoning up abundance of names and differences of Plants; but very short and bare in seeking out their virtues. It is better in my opinion, to know fewer Plants, and to understand their virtues withal, than to be able to reckon up the names of abundance, which many illiterate Gardeners are able to do; and to be quite ignorant of their faculties and Qualities.

Tribe I. *Mushrumps and Toad-stools.*

Since Nature, yea rather God himself the Author of Nature, contrives and works nothing without order; and that order is also most cleerly to be seen in Plants; therefore I think fit to begin with Mushrumps, and Puck-fists, which are as it were the Rudiments of Plants. Puck-fists grow within the Earth, without any stalk, leaf, fibre or thred. Mushrumps do some grow out of the Earth, others upon the stocks of Trees. Those which grow out of the Earth, are some of them soon ripe, in April: others come late, in Autumn; among which there is great difference, from their shape, color, and other Qualities; and some are fit to be eaten, others are venemous. The several kinds have in sundry nations their peculiar names. There is also a peculiar sort, round like a ball, sticking to the ground without any stalk, whitish in color, which being dry becomes poudery: it dries without any biting, and is therefore used to heal places where the Skin is galled off, and by Surgeons to stop Blood.

Crepitus lupi toe round Puck-fi

Agari

Among Mushrumps that grow on Trees, the most noble is Agarick, which is white, spungy, sweetish in tast, especially that which grows upon the Larch-Tree. It is very wel known

known to Physitians, for purging cold and flegmatick humors. Touch-wood, wel known for its use as tinder in striking fire, doth also grow on Trees. St. *Maries* Bal so called, or *Halcyonium*, is a kind of Toad-stool, also the Seaspunge. *Touch-wood.*

Tribe II. *Mosses and Mossie Plants.*

Moreover amongst the Rudiments of Plants are also the Mosses and certain mossie herbs: amongst the which notwithstanding some perfect Herbs are reckoned. Now Mos is an hairy substance sticking to the stocks of old Trees, upon the ground, and on stones, also swimming upon the water. And there is, I. Earth-mos, which they cal *Lycopodium*, Wolfs-claw, of three sorts, the greatest, middlemost, and smallest. II. Hitherto appertain certain creeping herbs, as hairy Mos, Golden Maiden-hair, and *Ros Solis*. III. The common Mos of Trees, and Broad-leav'd Mos or Lungwort, which heals the Ulcers of the Lungs. IV. *Lichen* Liver-wort, which grows to Stones, in dark and moist places. The Apothecaries cal it *Hepatica*, others cal it *Hepatica Petræa*, Stone Liver-wort, because it is good against inflamations of the Liver and Feavers proceeding from Choler. For it is cold and dry and a little astringent; whence it stops bleeding, and resists inflamations of the mouth. V. Sea-Mos, of which there are many sorts. VI. *Corallina* which is also a Sea-Mos, having a drying and astringent faculty, and kils Worms and drives them out the same day, to admiration. VII. *Fucus Marinus*, Seaweed: of which there are also some kinds; among which is the Sea-Oak so called. VIII. Hither may be referred the common Maiden-hair of the Shops, because of the likness it hath in its stalks to capillary Mosses: appropriated chiefly to the Breast and Lungs, whose gros humors it extenuates: also it breaks the Stone. IX. Wall-Rue, or white Maiden-hair, growing in moist places, and on old Walls; like in faculty to the black and vulgar Maiden-hair aforesaid. X. In this Tribe may be reckoned Duck-weed, which is as it were a Mos, swimming on the top of standing waters: it cools and represses Inflamation. *Corallina.* *Maiden-hair.* *Wall-Rue.* *Duckweed.*

Tribe III. *Grasses.*

In the third Tribe we rank Grasses, among which the first is the vulgar meadow Gras, with long, white, knotted and sweet roots, the decoction whereof is good for the Kidneys and Bladder, and opens their obstructions, and the obstructions of the Liver: it kils Worms also.

There are sundry sorts of Gras; Wood-Gras, Cats-tail-Gras, Cypress-Gras, Knot-Gras, Dog-Gras, Painted-Gras, Sorgh-Gras, Milet-Gras, Canary-Gras, Stanch-blood-Gras, Manna-Gras, Esculent-Gras, shining-Gras, Oat-Gras, Fox-Gras, Wild-Chamomel-Gras, Corn-Grats, Bulbous-Grats, Reed-Gras, Gras of *Parnassus*, Water-Gras, River-Gras, Rush-Gras, Panick-Gras, Sea-Gras, Flowry-Gras, Wooly-Gras, Hares-Gras, Broom-Gras, Gras-nobone, Clove-Gras, or Gilloflower Gras, Mous-tail, Spider-Grats, Sword-Grats or Sedg.

Tribe IV. *Reedy Plants.*

The fourth Tribe contains Reeds and reedy Plants. *Arundo*, a Reed, which the Greeks cal *Calamos*, contains many sorts. For there is in the first place the vulgar smal reed, which is cal'd *Phragmites*, good to tharch Houses and to fence Gardens; after that is the solid or ful Reed, which is not hollow, called *Nastos*, of which Darts are made. There is also the pipe Reed, the *Donax* or *Cyprian* Reed, the broad-leav'd Indian Reed or Cane. Also to the family of Reeds belongs the Water Cats-tail.

Among Reeds the most excellent are the *Calamus aromaticus* or spicy Reed, and the Sugar Cane. For though at this day Apothecaries use the root of the Tree *Acorus* in stead of *Calamus aromaticus*: yet that is not the *Calamus* of the Ancients, which was not a Root, but a reedy hollow Cane in *Syria* neer *Mount Lebanon*, and in *Arabia* and *India*; Which Reed though hitherto it hath been almost out of knowledg; yet it is now come to light again; and is every where to be had at the Apothecaries. It heats and dries, is gently astringent, a little biting, and by tenuity of its parts opens the passages of the Body, moves the Courses, and refreshes the spirits. *Calamus Aromaticus.*

Moreover, The Sugar Reed, or Sugar-Cane, is spungy and ful of pith, and within ful of a most sweet juyce, which either drops out of the Trunk being cut, or it is drawn out of the pith *The Sugar Cane or Reed.*

pith by boyling, which boyling is continued til the liquor congeal into Sugar, resembling Salt.

To this Tribe may be referred the several sorts of Flower de-luce, which differ chiefly in the colour of the flowers, and have their name from the Rain-bow which they represent in their partly-coloured flowers. There are two sorts especially now in use; the one is the vulgar which hath a blew flower, whose Root, especially the juyce pressed thereout, doth powerfully purge the water from such as have the Dropsie. To which belongs the small thin-leav'd Flower-de-luce, also the Chamæiris or ground Flower-deluce. The other hath a white Flower & Root which smels like a Violet, and therfore the Germans cal it *Viol-wortel* or Violet Root: it hath a spicy faculty, heats and extenuates, and is good for the Heart and Brain, but especially for Chest. There are also the *Dalmatian*, *Chalcedonian*, double flowred, and *Portugal* Flowers-de-luces &c. To this family belongs also the *Spatula fœtida*, *Xiris* or stinking Gladon, having a stalk and leaves like the Flower-de luce, but blacker and stinking, its flowers also are alike but lesser and of an obscure purple colour. Also the wild yellow Flower-de-luce. Nor is the Water-gladon with purple flowers to be shut out of this Tribe, though by others referred to the following Tribe. Some cal it *Junscus floridus*, and *Gramen arundinaceum*; *Dodoneus* terms it *Platanaria*, and *Matthiolus Sparganium*.

The Acorus verus. The *Acorus* also or *Acorum* belongs to this Tribe, which the Shops very erroneously do cal *Calamus Aromaticus*. And this is the true *Acorus*, in stead whereof the Apothecaries do somtimes badly make use of the bastard yellow Flower-de-luce, whereas their faculties are far different: for the bastard Orice is void of smel, cools and binds: but the true *Acorus* is of a spicy smel and tast, heats and dries, moves Urine, is good for Gripings in the Guts, and for pains of the Sides, Chest, and Liver. Also the Cyperus, long and round, *Cyperus.* and the bastard Cyperus. Now the roots of Cyperus do heat and dry, and are a little astringent, and therefore good to bring moist Ulcers to a Scar: Also they have a cutting faculty, and therefore are good for such as have the Stone, cannot Piss freely, and want their monthly Courses. Also Galangal the greater and lesser sort, which heats, and helps al cold Diseases caused by flegm, discusses Wind, and helps the Cholick. But the smaller sort is more effectual than the other. Some also refer to this Tribe Costus, Zedoary, and Ginger.

Tribe V. *Rushes.*

To the reedy Plants aforesaid, Rushes are neerest of kin, and therefore they make up the fift Tribe. Now they are all void of Leaves, and instead of Leaves have long round stalks, void of knots, and ending with sharp points. There are sundry even, short knotted Rushes which grow in the waters and watry places. *Schænanthum* is the flower of a certain odoriferous Rush. *Spartum* seems to belong to this Tribe. Also some refer the sorts of *Equisetum* or Horse-tail to this family: which have indeed thin rushy Leaves growing about the Joynts, but knots withal. To the sorts of Horse-tail also pertains the female Knot-*Asparagus* Grass which grows in moist places, and by Brooks and Rivers. Also *Asparagus* is reckoned amongst these; which word in general signifies the tender stalk of any Plant when it first springs up: but it signifies more peculiarly a Plant that sends forth such young stalks fit to be eaten. It is Garden or Wild; and of the Wild there are certain sorts.

Tribe VI. *Bulbous and Taberous Plants.*

Seeing among Bulbous Plants there are many which have affinity with certain reedy and rushy ones of the two former Tribes; therefore we marshal the Bulbous Plants in this sixth Tribe next to them; specially because there are some Bulbous Plants, one sort whereof is only bulbous; the rest agreeing with other Rushes even in the Root. Now a Bulbous (whence this Tribe is termed) is a certain kind of Root short and round, and consisting of many Skins or Scales one within another, as you see in an Onion. The first of these is the *Asphodelus bulbosus* Galeni, *Galen* his Daffodil with a bulbous root. And then there are other Daffodils, whose roots are not really bulbous, but long-round, somwhat like to Acorns, and of those also there are many sorts. I. There is one with a white flower, and that is greater or lesser, which in stead of Roots hath many thick fibres. II. There is also a white-flowred bulbous Plant called *Ornithogalum* Birds-milk, and Yellow Birds-milk, or *Ornithogalum of Narbon*. III. There are three or more sorts of a Bulbous Flower-de-luce. IV. Sin-

gle

gle Gladen, bearing flowers on both sides. V. *Sisynrichium*, the greater and lesser. VI. Sundry sorts of Hyacinths or Crows-toes, for there is an oriental one greater and lesser; there is the *Botroides* of two kinds; the hairy, the autumnal greater and lesser. VII. *Narcissus*, the Water Daffodil, of which there are many sorts; one purple in the middle; another yellow in the middle; and that is not of one kind, there being one al white and double, another Rush-leav'd, greater and less; a wild yellow one greater and lesser, and the Sea *Narcissus*. VIII. The Bulbous Stock Gilloflower, that with three leaves, and that with four, that with many leaves, and that of Autumn. IX. Sundry sorts of Tulips. X. the Wool-bearing Bulbous, and the *Flos Tigridis*. XI. Sundry sorts of Lillies, the White, the Purple, the Blood-red, of which there are some sorts. The *Hemorocallis* or wild Lilly which lasts but a day; the *Martagum*, the Crown Imperial. Now though there are sundry sorts of Lillies: yet the white Lilly is more used than any of the rest, which hath a rare virtue to soften hard swellings and ripen them, and to take away obstructions; of the flowers of this Lilly a neat Oyl is made, which assuages pain. XII. *Fritillaria*. XIII. *Colchicum*, Medow Saffron, which most cal *Ephemeron*; and which have wrongfully used in stead of *Hermodactilis*. Now there are two sorts of this *Colchicum*, *Ephemeron* or Meadow-Saffron; the first is of a strangling nature, & wil choak a man to death; the other strangles not and is properly called Meadow-Saffron: but the true *Hermodactil* differs from them both. XIV. The Lilly which is not bulbous, cal'd the Lilly convally, or the One-leav'd Lilly. XV. The true Saffron, whose flowers which are in use are hot and dry, doth recreate the Spirits and strengthen the Heart, breed cheerfulness, make al the Senses quick, cure the obstruction of the Liver and the Jaundice, move the Courses, provoke Urine, and incite to Generation; yet too much thereof is hurtful. There is a wild Saffron, a Spring Saffron of several sorts, and an Autumn Saffron. XVI. The Squil or Sea-Onion, which hath a rare cutting faculty, and is therefore commended against cold Diseases of the Brain and Nerves. XVII. *Panoratium*, a Sea-Onion so called, hath affinity with the Squil. XVIII. *Moly*, Ladies-Cushion, or Sea-Grass, the Narrow-leav'd, Broad-leav'd, and the Indian. XIX. The several sorts of Onions and Leeks, to which pertain the Rush-Leek, the Vineyard-Leek; Garden Garlick, and sundry sorts of wild Garlick, as the narrow-leav'd, broadleav'd or Bears-foot-Garlick, and that of the Alpes. XX. Many kinds of the Orchis, Gander-Goose or Dog-stone, which have sundry names from their shapes. XXI. Sundry sorts of *Palma Christi & Satyrium* or Ladies-Traces, Stander-Grass. Of which one kind is now in use, whose Roots are kept in the Shops, preserved in Sugar, and being of a temper hot and moist, are thought to be very good for Persons in a Consumption, and strongly to provoke to Generation. XXII. To this Tribe is referred and reckoned for an *Orchis* the *Bifolium* or Tway-blade, which most do cal *Ophris*; which is also of two kinds.

The white Lilly.

Saffron.

The Squil.

Ladies Traces.

Tway blade.

Tribe VII. *Corns and Pulses.*

To the seventh Tribe we may refer Corns and Pulses: amongst which Wheat is Captain, after which comes *Zea*, *Zeopyron*, *Secale*, or *Rogga* Rye, Barley, Oats, Turkish Wheat, *viz.* al such Grains of which Bread is made. But *Legumina Cerealea*, Pulses, *Galen* tels us are such as of which bread is not made: as Rice, Miler, Panick, Beech-Corn; though some count these Corns and reckon none for Pulses but such as are pulled up by hand. Amongst which nevertheless Authors reckon many things which are food only for Beasts, and not for men, whose seed is in dayly-use; such as are Beans, French Beans, sundry sorts of Pease and Hastifers, Vetches, and Tares; of which many sorts, Wild and Garden; Lentiles, Erets, Lupines, Sesamus.

To which family may be reduced such Plants as have some affinity to these, or which are bastard and corrupted Corns and Pulses, some of which notwithstanding are used for Foods such as are the Fox-tail, Wild and Garden-Flax, Hemp, (which others refer to the Trefoils or three-leav'd Plants) Garden and Wild; Fænugreek Garden and wild; *Hedysarum*, *Securidaca*, and Horse-shoo; *Galega*, Goats-Rue or Cocks-comb, which is of great efficacy against the Plague; *Onobrychis*, Earth-Acorns, *Astragolus*, *Anthyllis leguminosa*, *Stella leguminosa* of *Lobelius*, Birds-foot, *Aphace*, several sorts of Wild Vetches, Sea-Wheat, *Bromos* Wild Oats, Cow Wheat, Smutted Corn, *Orobanche* and *Anblatum* of *Cordus*, *Tribulus terrestris* or Caltrop. Some refer to this place *Cassuta* or Dodder, which removes obstructions of the Liver and Spleen, helps the Jaundice, moves Urine, and is good against Diseases springing from Choler and Melancholy also the Leguminous Capar is referred to this Tribe.

Galega.

Tribe VIII. *Trefoyls, Cinque-foyls, and Herbs of that Family.*

In the first place, there are many kinds of Trefoyls, or three-leav'd Plants: Meadow-Trefoyl or Clover, shrubby Trefoyl, codded Trefoyl, American Trefoyl, Heart-fashioned, spoon-fashioned, horn-fashioned, odoriferous Trefoyl, or Melilot. Also all the sorts of *Lotus* and *Melilotus*, *Cytisus* and bastard *Cytisus*, the *Medica*, the sorts of *Zapogus*, sour Trefoyl or Wood-sorrel, which *Pliny* cals *Oxys*, Golden Trefoyl, or Golden Liver-wort, Marsh Trefoyl.

Also there are sundry sorts of Cinquefoyls or Five-leaved Herbs: The great, the less, the Ash-colored, the creeping, the marrish or berry-bearing Cinquefoyl. Whereunto be-
Tormentil. longs Tormentil, the Root whereof resists putrefaction, is good against the plague, and moves sweat; it stops the bellies loosness, flux of blood, and the Courses. Also 'tis good for such as are fallen from on high, and who are suspected to have received some inward hurt. Moreover, there are other Plants also, which have commonly two Leaves opposite one to another, not unlike the sorts last reckoned, but at the end of the branches they re-
Ononis. semble Trefoyls, and may be reckoned in this Family. Such are *Anonis* or *Ononis*, Rest-harrow, the bark of whose Root moves urine, and breaks the stone: Strawberry Leaves,
Liquoris. wild and Garden Liquoris, whose Root makes the wind-pipe smooth, is good for the Chest and Liver, quenches thirst; cures the scabbiness of the bladder, and pain of the kidneys;
Broom, Broom, petty Broom. Now the seeds of Broom have a faculty to loosen the belly, provoke urine, and break the stone both in the Reins and bladder. Hence a Conserve made of the flowers thereof is very good to remove obstructions of the Liver and Spleen. *Hypericum*,
St. Johns-wort St. Johns-wort: of it an Oyl is made, most effectual to heal wounds. Also this Herb hath the faculty to provoke Urine and the Courses.

Centory. Centory the Lesser, which being beaten green, and laid on, cures wounds, and purges ulcers. It is exceeding bitter, and therefore 'tis called the Gall of the Earth, and cures Feavers, and hath its name thence in the German Tongue; it kils worms. *Flos Solis*, the flower of the Sun, like to *Cistus* and *Ledus*.

Sena. Sena, which is now known sufficiently not only to al Physitians, but even to the common people. For it hath a rare faculty to open, digest, clense, gently purge, and also wonderfully to comfort and strengthen al the members of the whol body; so that it is a purge for al Sexes, and for al long and melancholick Diseases most convenient.

Rue Rue hath no smal affinity with some Herbs of this Tribe already mentioned, both the wild and garden Rue, which is hot and dry, of subtile parts, discusses wind, cuts thick and clammy humors; and consequently cures shortness of breath and a cough proceeding of a cold cause; it moves Urine and Courses, and takes away the Appetite to Generation: among the wild sorts is reckoned also *Hermala*.

Fumitory Nor must we in this place omit Fumitory, which is hot, though accidentally by purging choler it cools, and therefore is by some said to be cooling, though falsely; it opens, and frees the Liver and Spleen from obstructions, purifies the blood, and provokes urine. And therefore it cures Feavers, and all Diseases springing from adust humors; and is most effectual and safe in curing the itch, and other diseases of the skin; since in the mean while it strengthens the Liver, stomach, and other bowels. Hither also must we refer *Thalictrum* or *Thalictrum*, Fluxwort, the greater and lesser. Finally, hitherto belongs Madder, to which Clivers, *Mollugo*, Ladies Bedstraw, sweet Wood-rowel, and other sorts thereof do retain; *Cruciata*, Cross-wary, Gentian.

Tribe IX. *Anemonies, Crowfoots, Cranes-bills.*

Next to the foregoing Tribe, we fitly rank Anemonies, Crowfoots, and Cranes-bils. There are many sorts of Anemonies, differing in Leaves, Roots, and Flowers. There is a tuberous sort; one with many Flowers; one that hath three Leaves. Hither some refer the Flower of Adonis, as also *Dentaria alabastrites*, or *Viola dentaria & pulsatilla*. To these also may be reckoned the greater and lesser hollow Root, which some wrongfully use for Round Birthwort Root.

Moreover, There are also many Crows-foots; some sorts of Garden Crow-foots; and divers wild ones. There is the simple tuberous Crowfoot, and that with the many flowers, the Grassie Crowfoot, the Illyrian, the Alpine, the greater and lesser Spear-crowfoot. In this Family may be reckoned Wolf-bane the greater and lesser yellow; also the little purple and blew one; also the *Napellus* and *Anthora*.

Thirdly,

Thirdly, There are many sorts of Cranes-bils; the tuberous, Herb Robert, the musked or muscovy, the Cretick, Doves-foot, Cranes-bill, *Geranium supinum*, Frog-like, Mountanous, &c.

Tribe X. *Gilloflowers, Rose-Campians, Violets, and the kinds of Loose-strife, and certain allied Plants.*

Gilloflowers, which some cal *Betonica* or *Vetonica*, and *Flores tunicis*, are of sundry sorts, differing both in the color and figure of the Flowers, and other waies. There is the great and the little, the single and double, the white and purple; also the feathered, wild, and proud Gilloflower. Also many sorts of Armenian flowers; among which the most remarkable is the Carthusians Gilloflower, and the *Viscaria* or Catch-fly. But among all the Garden Clove-Gilloflowers are most in use, which with the sweetness of their smel do wonderfully refresh the spirits, and are exceeding friendly to the Brain, Liver, Stomach, and Heart. Hence their Syrup is cordial, good against poysons, and the bitings of venemous Beasts, and is commended by late Writers to encrease blood, and strengthen the Liver. *Gilloflowers* *Clove-gilloflowers.*

Nor is there less variety of *Lychnides* or Rose-Campians; for first there is *Lychnis Coronaria*, to which belongs the Flower of *Constantinople*, and the *Lychnis* of *Chalcedon*. Moreover there is a wild one with a single, and another with a double flower; a sort whereof is *Ocimastrum* or bastard Basil, by some so called. Hither also belongs the Herb commonly called *Papaver spumeum*. Nor is bastard Nigella a stranger to this Tribe, nor Soapwort, Gentian, and *Cruciata*, or Dwarf-Gentian.

Thirdly, In this Tribe may be Ranked the purple Violets, with the sweet flower, both simple and double. These Violets are cold and moist, and the flowers are good for internal Inflamations of the Breast, and smooth the roughness of the Throat and Wind-pipe; allay the heat of the Liver, Reins, and Bladder; mitigate the acrimony of choler, and consequently take away the heat and thirst of Feavers, and strengthen. Also there is a wild Violet without color; also three color'd Violets, or Herb of the Trinity, which we cal Hearts-ease and Pansies. *Violets*

Then there is the *Leucoion*, or white Violet, with a single and a double flower. Also the yellow *Leucoium*, which the Arabians call *Keiri*; whose flowers and also the seed move the courses, bring forth the Secondine and child; the Oyl made of them is good to resolve cold humors, to asswage pains, and to strengthen the Nerves.

Among these are reckoned the *Viola matronalis*, or Matrons Violet, or *Lunaria Græca*; to which the *Viola Mariana* is of kin, or the *Viola Calathiana* or *Pneumonanthe*: as also *Flos ambarvalis*, commonly called *Polyganon*: to which appertain *Cervicaria major, media, minima.*

Next come the sorts of *Digitalis*, especially differing in the color of the flowers. Yea, among these may be numbred *Aquilegia*, chiefly distinguished by the variety of flowers: A dram whereof in pouder is given to such as have the Jaundice, to make them sweat. 'Tis commonly used to drive out the Meazles and smal Pox. *Aquilegia*

To this Tribe may be reduced *Lysimachium* or *Lysimachia*, Loose-strife, whose sorts are, the yellow, the purple; and there are many kinds thereof, some of which have the flowers upon the top of the stalk like a fore-top, or as an ear of Corn; others have them in Cods, which are therefore termed Codded Loose-strifes. There is also a sort which may be called the Shrubby Loose-strife. Among the bastard *Lysimachia's* there is reckoned a blue one. Moreover, because of the affinity of the flowers, we add both some water and marish Herbs: as Water-violets, Frogs-bit, white Water-Lilly, yellow Water-Lilly, Water Crowfoot, Water Archer, the Marish Marigold.

Tribe XI. *Other Plants remarkable for their Flowers.*

To this Tribe many and sundry Plants may be referred, among which in respect of the greatness of the Flower, *Chrysanthemum Peruvianum*, or the Flower of the Sun of *Peru*, may justly be Captain. In the next place Elecampane, whose Root is of great use, being good against poysons and biting of poysonous beasts, is helpful to such as cannot fetch breath without sitting upright, cuts gross humors in the breast, and cures the Cough, moves Urine and Courses, helps the stomach and digestion. *Elecampane*

Next come the other sorts of *Chrysanthemum* or Golden flower, which are commonly

called *Oxen-eyes.* To which the sorts of Chamomel are allied: also *Eranthemum*, or flower of *Adonis*, which some reckon among the Anemonies, as we said before.

Chamomel Chamomel is frequently used in Physick: it heats, is loosning, discussive, mollifies internal and external pains. Of kin to Chamomel, and as it were a wild Chamomel, is *Cotula fœtida.* Also the kinds of Marigolds are to be referred to this Tribe, as also the *African* Flower: also sundry sorts of Blew-bottles: *Tragopogon* Goats-bead, and *Scorzonera.*

Nigella To this Tribe also *Nigella* or Gith is a retainer, whose seed heats, dries, cuts, and extenuates: being smelt to frequently it dries up the distillations of the Head: taken inwardly, it discusseth winds, cuts flegm, moves the Courses, helps shortness of breath. Pellitory also.

Hither also are to be referred the Daisies both Garden and wild: and the *After atticus*, or Star-wort. Nor are the sorts of Tansies unlike in flower, as the common sweet Tansie, the crisped, the Tansie without smel, the little white Tansie. Also *Matricaria* or Feaverfew belongs to this sort, which others reckon among the Corymbiferous Plants, that

Tansie bear clusters of Berries. Now Tansie is an hot and dry Herb, and bitter: it kils worms,

Feaverfew moves Urine. Feaverfew is hot in the third, dry in the second degree: it opens, clenses, is good for the Womb, and brings away the dead child: it cures the Tissick, Melancholy, and the stone. Peony brings up the Rear in this kind, having a goodly Flower. The Root whereof is especially good against the Falling-sickness, and strengthens the Brain and Nerves.

Tribe XII. *Poppy, Henbane, Nightshade, and Herbs of kin to them.*

Poppy First there is Garden Poppy of many sorts, differing chiefly in the flower and seed. All

Opium Poppies have a cooling sleepy faculty; but the black is the strongest. Of Poppy *Opium* is made, which is the juyce which drops out of the Heads of black Poppy in hot Countries, the said heads being cut; and it is afterwards condensed. That of *Thebes* is most commended. Now it is bitter, of a strong smel, causes sleep and stupifies. Touching the Quality thereof Physitians are at variance: while some make it cold in the fourth degree, because of its sleepy stupifying faculty; others say it is hot, in regard of its bitterness and acrimony. But now adaies not only Chymists, but other learned Physitians hold, That sleep and stupefaction is caused, not so much by its coldness, as by a stupefying Sulphure, which is found also in hot things, as in Spirit of Wine: and from such a Narcotick Sulphur *Opium* hath al its force; but its bitterness it hath from a bitter salt. A token whereof is this, That being largely taken it causes a drouzy dulness, with an itching al the Body over: and the Turks use their *Maslach* to make them courageous in Battel, wherewith they become as it were drunk. After this comes Red Poppy, or Corn-Rose; also horned Poppy, of which there are some kinds, and *Hypecoon.*

Also Henbane is manifold, white, black, yellow; Henbane of *Peru*, which they cal Tobacco. It also, though hot and dry in the second Degre, hath nevertheless a Narcotick Faculty; the smoak taken in a pipe draws Rheum out of the Brain; the juyce given to strong persons, purges by stool, the operation being followed by a deep sleep. Some give the water stilled out of the Leaves in Agues before the fit, to drive the same away. An Oynt ment is made thereof good for Wounds.

Winter-Cherries There is Garden Nightshade, and Winter-cherry Nightshade, of which there is an outlandish sort. The Winter Cherries have a notable faculty to provoke Urine, and to bring gravel from the Kidneys and Bladder. There is also a deadly sleeping Nightshade. Hither also belongs the Mandrake. Also of this Family are the Apples of Love, Golden Apples, or mad Apples of *Æthiopia*; also the Thorn-apple; and *Strychnodendrum*, or Woody Nightshade.

Tribe XIII. *Endives, Cichories, Lettices, and Plants of kin to them.*

Endive, Cichory, Dandelion, Gum-Cichory To this Tribe belongs Garden Endive, broad leaved and wild Cichory, Dandelyon, Gum Cichory; al which are cold and dry, bitterish, whence they open and clense, and are a little astrictive; whereby they strengthen the Bowels. Hence they are most profitably and most frequently used in opening the obstructions of the Liver, and other Bowels, and in clensing away cholerick humors. Sundry sorts of Hawkweed are of this Tribe; also Groundsel, Ragwort, Sow-thistle, and sharp thistle; many sorts of Garden and wild Lettice. Al Lettices moist and cool, help a cholerick stomach, and procure sleep.

Tribe XIV.

Tribe XIV. *Orach, Beets, Colewort, Docks, Rocket, Mallows, Cresses, and Herbs of kin to these.*

In the first place there are sundry sorts of Orach; The Garden, the Wild, the Sea Orach; *Bonus Henricus & tota bona*, English Mercury; which some nevertheless refer to the sorts of Docks: *Pes anserinus*, Goos-foot. Then there are Blites, a greater, a lesser, a spotted; to which appertain the sorts of *Amaranthus Purpureus*, or purple Flower-gentle.

Thirdly, there is Spinage and some kind of Beets; and among them the red Beet, whose Root is eaten as a Sallet with Vinegar and Oyl; also some kind of Garden Colewort, also the wild, one sort whereof they cal *Perfoliata*, Thorough-wax.

Fourthly, To this Tribe Borrage and Bugloss may be referred; to which *Anchusa* or Alkanet, and *Echium* Vipers-borrage, are added. Now Borrage and Bugloss (especially their flowers) have a very great faculty to strengthen and cheat the heart, also they refresh and recreate the spirits; and therefore Conserves and Syrups are made of them, which in Melancholick Diseases, and such as proceed from adust humors, are very good. *Bugloss, Borrage,*

Fiftly, Mercury, male and female, *Cynocrambe*, Dogs-Cabbage, and *Herba impatiens* the impatient Herb, or Touch me not; and Pellitory of the wal, which is cold and moist, cleanses, is good for imflammations and burnings. The Leaves applied in manner of a Caplasm to the share, with Oyl of sweet Almonds, are an help to such as have the stone, and provoke the stopped Urine. *Pellitory of the wal.*

Sixtly, The kinds of Docks, as the wild Dock, the Garden Dock, Monks Rhubarb, red Dock, Sorrel, tuberous Sorrel, smalleſt Sorrel. Now Sorrel cools and dries, hinders putrefaction, provokes Appetite, and is therefore good for continual Feavers and Pestilences. *Sorrel*

Seventhly, Garden-Mallows with the double Flower, which is called also the Tree-Mallow, and over-sea Rose; also crisped Mallows, wild Mallows, Marsh Mallows, *Abutilon* yellow Mallows; Vulgar *Alcea*, and *Alcea Vesicaria*; the Cotton-plant.

Eightly, We refer to this Tribe such Herbs as have a biting tast: Amongst which the Captain is Water-Cresses, and a sort thereof called Cuckows Flower; Brooklime; Scurvy-grass; Garden Cresses; Winter Cresses; Indian Water-Cress; Garden Mustard, and wild; al the *Nasturtia* or biting Cresses are hot and dry, provoke Urine, expel the Gravel and stone, and are therefore good for the Kidneys and Bladder. But they are especially excellent against the Scurvy, and principally Scurvy-grass. *water-cresses, scurvy-grass.*

Also Garden Rocket, and wild Rocket: to which may be added smal Celandine; herb Dragon, wild Dragon or Neesewort: several kinds of *Thlaspi* or wild Mustard; among which is that of Candie; *Erysimum*, Bank-cresses; *Lepidium*, Dittander or Pepperwort. The Turnep, the Navew, *Rapistrum* or Charlock; Garden Rhadish, *Lampsana* or Dock-cresses, which others are wont to refer to the Hawk-weeds.

Finally, we add to this Tribe the Nettle, which is burning and stinging, or dead Nettle. The stinging Nettle hath some sorts: they are al hot and dry, being boyled they loosen the belly by abstersion, drive out the Urine and Stone; the seed provokes to Generation; it digests crude humors in the Chest, and is therefore good for them that cannot breath unless they sit or stand upright: it is a present Remedy against the poyson of Hemlock, and the malignity of Henbane and Toadstools. There are also divers sorts of dead Nettle and Arch-Angel. *the Nettle*

Tribe XV. *Mint, Sage, Horehound, Bawm, and Herbs of kin to them.*

In the first place, there are many kinds of Mint: and then there is bastard Mint, *Sisymbrium*, Mountain and field Calamint, Cats-mint, Sarazens Mint. Mint is hot and dry, hath a rare faculty to strengthen the stomach, and help digestion, stops vomiting, dispels wind, ceases gripings, stops flux of the belly, and the whites; it hinders Milk from curdling in the stomach, hinders conception. Calamint is also hot and dry, good for the Tissick, stops gripings, heals the womb, kils worms, brings down the courses, and is especially good for the womb, and furthers conception. *Mint* *Calamint*

In the second place there is Sage the greater and lesser sort, which heats and dries, opens, is especially good for the Head and nerves, and is good for the cough and spitting of blood, and against the bitings of venemous Beasts. Wild Sage; *Sclarea & Horminum*, Clary, of which also there are divers sorts. *Sage*

Thirdly,

Horehound Thirdly there is Horehound white and black: now this is hot and dry, opens obstructions of the Liver and Spleen; purges the Chest, and is therefore good for Persons in Consumptions who have no Feaver, it brings away the Courses and the After-birth: 'tis good against Venoms and bitings of venemous Creatures.

Bawm. Fourthly Bawm, it is hot and dry in the second degree, a great and good friend to the Brain and Heart, recreates the Spirits and comforts the Memory; 'tis good against Poysons and helps the bitings of Dogs, Scorpions and Spiders, being outwardly applied; it moves also the Courses.

Basil. There are also other Herbs, like these in smel, which may be justly reckoned in this Tribe, as Basil, which some think is called *Ocimos* because of its sweet and savory smel. Being smel'd to its good for Head and Heart; the Seed helps the Diseases of the Heart, Discusses sorrow and sadness proceeding from Melancholy, and begets Mirth and Cheerfulness.

Pennyroyal Penny-royal is hot and dry with a certain bitterness and astriction; it hath a rare faculty to open obstructions, and to cut thick humors, to move Urine, and especially the Courses, also cures the Stone, Dropsie, Gout and Palsie.

Origanum. True Wild Origanum or wild Marjoram is hot and dry in the third degree, hath a very great faculty to cut, attenuate and scour, and is good against Poyson. Therefore its decoction is profitably given to such as have the Asthma, Convulsion, Dropsie, and such as are bitten by a Serpent. To Origanum belongs Trag-Origanum, or Goats Origanum.

Wild Time Wild Time *Serpillum*, is an Herb very much of kin to Peny-royal, and sends forth a most sweet and fragrant smel. It provokes the Courses, plentifully brings down the Urine, asswages Headach coming from a cold Cause, allaies the Griping of the Guts, and is good against the Lethargy.

Stæchados Arabian *Stæchados*, most effectual against al Diseases of the Head from a cold Cause.

Hyssop. Also *Polium* and Hyssop, which being hot and dry in the third degree, digests, opens and discusses. Therefore boyled with Honey and drunk, it helps much to digest and bring out flegm in the Chest, and frees the Lungs stuffed with vitious humors; and helps an old Cough.

Mother of Time. Time. Savory. Mother of Time, Time, Savory, are plants of affinity; have in a manner the same faculties, being hot and dry; being mingled with our meats, they help the Concoction of the Stomack, free the Womb distended with Wind; are thought to help the Palsie and al sleepy Diseases.

Lavender and Spike. To these may be added Lavender and Spike, being hot and dry Herbs, spiritful, oyly and odoriferous, most effectual in cold Diseases of the Head. Hence their water applied to the Fore-head and the Temples is good for the Palsie of one side of the Body, and for the Falling-sickness; and a Conserve of the flowers is effectual against the Apoplexy and cold Diseases of the Brain.

Rosemary. Next to these marches Herb Mastich or *Clinopodium* and Rosemary, which is hot and dry, with some astriction, heals al cold Diseases of the Head and Brain, dries the Brain, whets the Senses and Memory, is good for the Poze, strengthens the nervous parts, comforts the Womb, and helps the old fluxes thereof.

Marjoram Marjoram, which also heats and dries in the second degree, also helps the cold Diseases of the Brain; and snuffed up the Nose it causes sneezing and brings away flegm, provokes the Urine and Courses.

Betony. Betony is also hot and dry in the second degree, and cutting; 'tis good for the Falling-sickness, and cold diseases of the Head, purges the Breast and Lungs, opens the obstructions of the Liver and Spleen, cures the Jaundice, strengthens the Stomack, and helps Digestion; moves Urine, breaks the Stone, is good for the pain of the Kidnies and Bladder, moves the Courses, allaies Mother-fits, is good against the bitings of Serpents and Venemous Beasts, is good for Worms and the Sciatica.

Dittamus. *Dictamnum verum* or *Creticum*, Dittamus of *Crete*, being in faculty like Penny-royal, moves the Courses, expels the After-birth and dead Child, facilitates Child-birth, is good against the stingings of venemous Beasts.

Scordium. *Scordium* heats and dries, cleanses and purges the Bowels, moves Urine and the Courses, draws gross and purulent humors out of the Breast, and is therefore good for an old Cough. 'Tis usefull mixed with Antidotes against Poyson.

Tribe XVI. *Scabious and Plants of kin thereto.*

There are many kinds of Scabious, the greater, the lesser, the middlemost, the greatest, the Spanish, and that of the *Alpes*: It is hot and dry in the second degree, attenuates and cuts thick and clammy humors; therefore it cleanses the Lungs, helps the Cough and shortness of Breath, is good for the Scab, effectual against the Plague, pestilent Fevers, and the bitings of venemous Beasts, and is good to move sweat in such Diseases. *Scabious.*

Hereto belongs *Stæbe*, Devils-bit, *Jacca nigra* or black Matfellon. Among these some do reckon the Blew-bottles mentioned before in the eleventh Tribe; also the Royal Comfreys, or Flower Royal, and the *Serratula* or Saw-wort, Centaury the great, Sarasens Confound, *Virga aurea*, or Golden Rod, Plants good to heal Wounds. This Tribe admits also other Herbs, as Agrimony, which hath an attenuating, opening faculty, and is especially good for the Liver; also the Herb of Kunegund or *Avicennas Eupatorium*. *Agrimony.*

Also the kinds of *Veronica* or Fluellen, which is good for obstructions of the Liver and Spleen, brings forth the Urine and Stone, heals the Scab and all Diseases of the Skin, wounds, and especially cancerous Ulcers. Also it helps those that have the Tissick, and who cough up purulent matter. *Veronica*

Vervain, Ground-Oak, and *Teucrium* or Tree-Germander, with Ground-pine or *Chamæpitys* and their sorts. Now *Chamædrys* or Germander, and *Chamæpitys* Ground-pine, have virtues much alike. *Chamædrys* opens obstructions of the Liver and Spleen, helps the Dropsie, moves the Courses, and is good against the biting of Serpents; also *Chamæpitys* opens obstructions, cleanses the Kidnies, moves Urine and the Courses, strengthens the Nerves, helps the Sciatica and other diseases of the Joynts; wherefore 'tis commonly called *Iva Arthretica*, and *Herba Apoplectica*. *Chamædrit* *Chamæpitys.*

Finally Eye-bright, which by a strong faculty comforts the Eyes, and helps dimness of sight. *Eye-bright*

Tribe XVII. *Woolly and Downy Plants.*

Among those Herbs whose Leaves are covered as it were with Down; the first is *Gnaphalium*, Cud-weed or Cotton-weed: And then the sorts of Mous-Ear, *Leontopodium Matthioli*, yellow Stæchados: the third Scorpion-Grass, the sorts of Mullein, and Ethiopian Mullein: To which also other Herbs are referred, though not downy, as *Blattaria*, Moth-mullein, the Primerose, which is good for diseases of the Joynts and Nerves, also for Ruptures and Dislocations of the Joynts, and the Stone in the Kidnies and Bladder; Bears-Ear. Also Hounds-tongue, and *Anchusa* or Alkanet, are by some reckoned in this Tribe. *The Primrose.*

Tribe XVIII. *The House-Leeks.*

To this Tribe belong the kinds of Houseleek, as the great branching Houseleek, the smal Houseleek, that is cal'd *Illecebra*; *Telephium* and *Crassula*.

Aloes, of which is made a thickned Juyce wel known in Physick, it purges yellow choler, helps the Stomack and Brain, resists putrefaction, opens the Hemorrhoids, moves the Courses, cleanses Wounds and brings them to a Scar. *Aloes*

Purslane, which is cold and moist and binding, helps the Teeth when they are on edg, kils the Worms in Children, especially if they have a Feaver withal, is effectual against spitting of Blood, the Bloody Flux, and voiding of Blood. Some also refer to this Tribe the *Radix Rhodia* or Rose-wort, especially good for the pains of the Head. *Purslane* *Radix Rhodia.*

Tribe XIX. *Bindweeds, and of Twining Plants.*

Of this Tribe are Briony, Wild Vine, white Vine, *Dulcamara* or Bitter-sweet, black Bindweed, Indian Bindweed, Blewbel Bindweed.

Scammony, the Juyce whereof, (called by the same name) is famosly known, being an effectual purger of Choler and wheyish Humors; being prepared and boyled in a Quince, 'tis called *Diagridium*.

The *Smilax lævis* greater and lesser, or the greater and lesser Bindweed; the *Smilax aspera*, the Hop, the *Jessemine*, *Periclymenon* or Woodbind, *Hedera clematis* Creeping Ivy, *Daphnoides* or *Vinca Pervinca*; *Flammula* or Spearwort, and creeping Chickweed; Ground-Ivy, Twopenny-wort, wild Tansie or Silver-weed, *Soldanella*; *Mechoacan*, which

was

was unknown to the Ancients, and is now in great use; it purges Flegm and watry Humors, is good for the Falling-sickness, the Gout, the Tissick, Colick, and Mother fits. Hither also may be referred *Epithimum*, *Polygonum mas*, male Knot-Grass, *Anagallis* or Pimpernel; Rupture-wort or *Herniaria*, most excellent for Ruptures, whence it hath its name; which they say doth also move Urine and break the Stone. Some say 'tis especially good to comfort the Sight.

Herniaria, or Rupture wort.

Tribe XX. *The Cowcumber, Gourd, and Plants of kin to them.*

In regard of their long crawling stalks wherewith they creep on the ground, we joyn to the former Tribe Cucumbers, Citruls, Muskmelons, Pompions, Gourds: of All which there are many sorts. Hereto appertains *Coloquintida* or wild Gourd, Balm-Apple, *Balsamina* which is a wound Herb: and the Oyl wherein the fruit hath been steeped after the seed is taken out, is good for Burnings, Burstness, Pains and Ulcers of the Dugs.

Balsamina

Tribe XXI. *Thistles and Thistly Plants.*

Carduus Mariæ.

In this Tribe is Garden Bears-breech, *Carduus Mariæ* or Milky Thistle, which removes obstructions of the Liver and Spleen, and purges the waters of such as have the Dropsie. The seed is said to be good for Convulsion fits of Infants, and to help such as are bitten by a Serpent; and it is now frequently used for the Pleurisie. The Globe-headed Thistle or Roundheaded Thistle, the Downyheaded Thistle, the Goldenflowred Thistle, the Star Thistle, the Artichoak, the Chameleon, *Spina Solstitialis*, Venus basin, Shepherds Rod: *Carduus Benedictus*, the blessed Thistle, commonly cal'd *Carduus*, which is hot and dry, cleanses and opens, resists Poyson, opens obstructions of the Bowels, cures inveterate Feavers, kils Worms, moves Urine, is good against the Stone. Wild or Wood-Thistle; Garden and Wild *Carthamus*: *Eryngus* and *Chrythmus*; *Eryngus* moves Urine, and the Courses, staies Gripings, helps those that are Hepatick and Nephritick, incites to Generation. Also *Cirsium*, or soft Thistle.

Carduus Benedictus

Eryngo Roots.

Tribe XXII. *Tufted Plants, that have Clusters of seeds on the top.*

Fennel In this Tribe Fenel is the Captain, whose Roots open obstructions, provoke the Courses, move Urine. The seed comforts the Stomack, dispels Wind, comforts the Sight, encreases Milk, drives out the Urine and Stones.

Anis. Anise is very much of kin to Fenel, it also expels Wind, provokes to Generation, helps shortness of Breath.

Carway. Caraway, Its seed is hot and dry in the third degree, discusses Wind, helps Digestion, moves Urine.

Dill. Dil, whose seed boyled encreases Milk, allaies Gripings, helps the Hiccup though but smelt unto.

Cumin. Cumin, whose seed is also hot and dry in the third degree, it discusses Tumors and Winds, allaies Gripings, outwardly applied; being drunk it is good for a cold Breast, being beaten and mixt with Vinegar it stops bleeding of the Nose by smelling thereto.

Coriander. Coriander, whose seed prepared, (that is to say, steeped in Vinegar and dried) taken after meat drieth up the moisture of the Stomack, consumes the Spittle, expels Worms, and moves Urine.

Ammi or Bishops-weed, Carrot, *Libanotis* Hogs-Fenel, Bears-breech, Hercules Woundheal, *Asclepium*.

Lovage. Lovage, whose Roots drunk with Wine help the digestion of the Stomack, discuss Wind, move sweat, provoke the Courses and Urine, bring away the After-birth, are good for Mother-fits, heals the biting of Serpents.

Angelica. *Angelica*, which is good against Poysons and the bitings of venemous Beasts, dissolves clotted Blood, purges the Chest.

Pimpernel Mountain Siler, Pimpinel, hot and dry in the third degree, whose Roots move Urine, break the Stone, provoke the Courses, open the Liver, dispel Wind, ease the Colick pains, is good against Poysons.

Master-wort *Imperatoria* or Master-wort, whose Root is hot and dry in the third degree, of thin parts, digests cold Humors, moves Sweat and Urine, dispels Wind, is good for Nephritick and Hydropick Persons.

Herb

Herb Gerard, Fennel-Giant, Hogs-Fennel: Garden and Marsh Smallage, Mountain Smallage, Persley, which moves Urine and the Courses, and drives out the Stone: *Hippoſelinum*, Chervil, *Smyrnium*, *Caucalis*, Sweet Cicely, *Gingidium* or Tooth-pick, Hemlock, *Cicutaria* bastard Hemlock.

Filipendula

Filipendula, which is hot and dry, opens and cleanses with a certain astriction; the Decoction of the Roots drives out the Urine and Stone: some commend the pouder thereof against the Falling-sickness.

Meadow-sweet.

Meadow-sweet, *Thapsia*, or stinking and deadly Carrots, Parsneps, Carrots, Valerian, whose Roots are good against the stingings of venemous Beasts, and the Plague; they take away the Strangury, Cough, Winds; help faults of the Eyes, and comfort the Sight.

Valerian.

Tribe XXIII. *Berry-cluster bearing Plants.*

I think fit to place in this Tribe such Plants as bear Clusters of Berries or seeds and are therfore called *Plantæ corymbiferæ*; for *Corymbus* being a round bunch of Berries such as we see in Ivy, these kinds of Plants have thence their name: such an one is Mugwort which brings away the Courses and After-birth, also the Child, and drives out Urine and Stones.

Mug-wort.

Yarrow, which cleanses with astriction, glews together wounds, stops Blood flowing from any part, staies the Courses, and heals the Bloody Flux.

Yarrow.

The sorts of Tansies, whose flowers in Wine or mul'd Sack kils and drives out Worms, dissolves the Stone, and brings away Gravel.

Tansie.

Matricaria or Feverfew, as the name shews, is good for Women troubled with pains in their Wombs both inwardly and outwardly applied, discusseth Wind and wonderfully strengthens the Womb.

Feverfew.

Ambrosia, *Botrys*, Southern-wood.

Wormwood is a common Plant, but of manifold use, very bitter, very good for a Stomack troubled with Choler; for it scoures it away, by Stool and Urine: It strengthens the Stomack, encreases appetite, comforts the Liver, and opens its obstructions, expels bad humors by Urine; and in this respect it is with great profit used against long Agues, especially Tertian, which at length bring the Patient to a Cachexy.

Wormwood

Chamomel, *Cotula Fætida*, stinking Chamomel, which have been reckoned up in Tribe II.

Tribe XXIV. *Ferns and ferny Plants.*

All Plants whose Leaves are placed along the stalks like wings, may be called Ferns. There is first male and female Fern; to which Polypody is of kin, which cleanses away and digests thick and clammy humors: most say it purges, but experience shews it purges little or not at all; yet it is good to mingle with other Purgers, especially of Melancholy. Oak Fern.

Polypody.

Harts-Tongue, to which though others ascribe other virtues; yet experience tels that it is good for Diseases of the Spleen, whose obstructions it opens, asswages its hardness and swelling, and is good also for the like Diseases of the Liver. *Hemionitis*, or Milkwort.

Harts-Tongue.

Scolopendrium, Ceterach or Finger Fern, is of rare virtue to open and asswage the swelling of the Spleen, cure the Jaundice, break and expel the Stone; *Lonchitis*, great Spleenwort. To these also may be added *Lunaria* or Moon-wort, and *Ophioglossum* or Adders-Tongue.

Ceterach.

Tribe XXV. *Milkie Plants.*

Besides the forementioned there are other Herbs that have a milky juyce in them; as all the kinds of Spurges, *Characias*, with its sorts: *Cyparissias*, *Myrtoidis*, *Paralius*, *Helioscopius*, the broad leav'd, narrow leav'd, Knobby, and the woody, all the sorts of *Esula*, and *Pytiusa*, as *Lathyris*, *Peplis*, *Peplion*, *Chamesyce* or Ground-Fig. The *Esulæ* do purge vehemently Choler and Flegm, move Vomit, burn the Throat, and exulcerate.

Esulæ.

Tribe XXVI. *Nervous Plants.*

In this Tribe we may place all the sorts of Plantane: Now Plantane cools and dries, is astringent and abstersive, and hath mixed faculties: it cures Tetters and Inflammations, is good against all fluctions, yea of Blood; resists Putrefaction and strengthens the parts, and is good against Poysons; Swines-Cresses, All-bone, Fellon-wort.

Plantane.

Psyllium *Psyllium* or Fleawort, whose seed is cold in the second degree, temperate as to moisture and driness, according to *Galen*. Its Mucilage mitigates burnings within and without the Body, is good for exulcerated Guts: yet the frequent use thereof hurts the stomach. Hitherto also some refer Hounds-tongue; Star-wort, or the Harts-horn of *Dodonæus*; Woad, Toadflax, and *Linosyris* or Golden Star-flowered Toadflax, Shepherds pouch, *Vincetoxicum* Knot-grass, *Vincetoxicum* or Indian Swallow-wort, which as the name shews, is good against poyson.

Tribe XXVII.

The remaining Plants which could not conveniently be reckoned in the foregoing Tribes, we put al together into this last Tribe, and leave it to further consideration, how they may *White Hellebore* be better digested and disposed. And in the first place we rank white Hellebore; whose Root purges by Vomit, but very violently, kils the child in the womb, kils Mice mixed with honey and flour; also the pouder drawn up into the Nose causeth sneezing. *Helleborina*, bastard Hellebore, our Ladies slipper.

Black Hellebore After the white comes black Hellebore, which purgeth melancholy, and therefore cures madness, Hypochondriacal melancholy, those troubled with the spleen, Quartan Ague, Falling-sickness, and al Diseases proceeding from Melancholy.

Ricinus *Ricinus*, or *Palma Christi*; it heats and dries, its seeds purge choler and water by stool.

Ladies Mantle Ladies-Mantle and Sanicle, which have the faculty to heal wounds.

Sanicle *Garyophyllata* or Avens, whose Root smels like a Clove, whence it hath its name, it heats and dries, is good for the stomach and Liver, dissolves blood clotted within the body, and helps such as are bit by venemous Beasts.

Avens *Asarum* or Asarabacca, whose Roots cause vomit, and purge out thick and flegmatick humors: they move Urine and the Courses, remove obstructions of the Liver and Spleen, and so are good for the Dropsie and Jaundice.

Asarabacca *Aristolochia* or Birthwort long and round, so called because 'tis good for women in child-bed whose after-births it brings away: also it moves the Courses, and is good for the Tissick and Spleen. *Arum* or Cuckow-pintle, whose Root cuts thick humors in the chest and elsewhere. Dragon, water Dragon.

Birthwort long and round. *Bistorta* *Bistorta* or Snakeweed, whose Root cools and binds, and therefore stops the loosness of belly and flux of blood, is good for exulceration of the Guts, strengthens the inner parts, resists putrefaction and poyson, strengthens and fastens the Gums. Bindweed, Herb Paris, water Pepper, Arse-smart.

Cuckow-pintle *Colts-foot* Colts-foot, whose green Leaves do somwhat cool, and therefore they are good to apply to hot Ulcers. Being dried they are hot and dry, and moderately biting, and their smoak taken in a Tobacco pipe helps shortness of breath; also the Root is used to the same purpose, and against the cough, whence 'tis called *Tussilago*.

Thorow-wax *Perfoliata* or Through-wax, is bitter and astringent. The Decoction or pouder thereof is given to such as are bursten and fal from on high; and represses the starting Navils of children.

Great comfry *Symphytum* or Comfry, of which there are certain sorts: The great, which cools, contracts, and binds, heals Ruptures and broken Bones, stops spitting of blood and other Excretions thereof, and is good for the Bloody flux, and most effectual to sodder wounds.

Lungwort: Hereto belongs spotted Comfrey or Lungwort, good for ulcers, and other diseases of the *Self-heal:* Lungs. Also Bugle and Rock-comfrey; and finally, *Prunella* or Self-heal, which is commended against the blackness of the Tongue in burning Feavers.

Tribe XXVIII. *Of Shrubs and Bushes.*

Shrubs are The Bramble, greater and lesser; the *Cistus* or Holly-Rose, the red Corants, the Barbery Bush, Goats-thorn; *Acacia*, the Slo-bush, the Buck-thorn, white thorn, Holm, Broom, Tamarisk, bastard Dittany, bastard Sena, Rocket, Black-berry-bush, the Myrtle-bush, the Dwarf-Myrtil, *Agnus Castus*, Privet; the Pipe-bush, Curriers Sumach, Box, Hounds-tree, Black Aller or Butchers-prick tree, Spindle-tree.

Tribe

Tribe XXIX. *Trees.*

There are many sorts of Trees, but not so many as of Herbs. There are many kinds of vulgar Apple-trees; also which more belong to this place, there is the Citron tree, the Limon Tree, the Orange Tree, the Pomegranate Tree, the Quince Tree, the Peach Tree, the Apricock Tree, the Almond Tree, the Pear Tree, of which again there are many kinds; the Prune and Plum tree, the Cherry tree, the Mulberry tree, the Fig tree, the Medlar tree, the Cornel tree, the Service tree, the Jujubee tree, the Chestnut tree, the Walnut tree, the Hazel tree, the Pistachio Nut tree, the Bladder Nut tree, the Palm tree, the Olive tree, the Bay tree, the Rose tree, the Juniper tree, the Oak, the Holm, the Cork tree, the Beech tree, the Ash tree, the Alder tree, the Cedar tree, the wild Ash tree, the Poplar, the Elm, the Linden, the Birch, the Willow, the Elder, the Lote, the Savine, the Cypress tree, the Tree of Life, the Eugh tree, the Pine tree, the Pitch tree, the Fir tree, the Larch tree, the Turpentine tree, the Lentisch tree.

And thus you have a Catalogue of the chief Plants, which I have therefore set down, both that al men, but especially our idle Disputers (who alwaies stick in the same general matter, and yet think themselves rare Naturalists) may see by the example of Plants how great the amplitude of Nature is, and how that which we know is the least part of what we are ignorant of: also that such as are studious of the knowledg of Plants might have occasion to consider how there may be a Method in Herbarism, and how al Plants may be reduced to some certain Tribes: Which though I have not here finished and brought to perfection, yet I have laid the Foundation. And not to speak now of others; *Andreas Cæsalpinus* in his Sixteen Books of Plants, undertakes a laborious Method: For after in the first place he hath explained Trees and Shrubs; he propounds the variety of Herbs according to the difference of their Seeds. And in the first place he describes such as bear single seeds under every Flower, or have a single receptacle of seeds: Secondly, such as contain two seeds or receptacles of seeds, under the same flower: Thirdly, such as contain four, or more: And at last such as have no seed.

But though this distinction of Plants seems to be laborious and curious enough, and is therefore commended by some, yet I see not what Foundation it hath; seeing those Plants are joyned in one and the same Tribe, by reason of the agreement of their seeds, which neither agree in any signature, nor any other waies. As for example sake, in the fourth Book, what agreement is there betwixt Valerian and *Spica celtica*, Hemp, Hops, Beets, Wheat and other Corns? In the Fifth Book, how do Cowcumbers and Gourds agree with Dwarf-Elder, Nightshade, Indian Pepper, Lilly Convalley? In the Sixt Book, what agreement is betwixt Rose Campion, wild Turnep, Twopenny grass, and Purslane? And the same may be said of the rest.

But I leave it free for any Body to change and perfect this Method as he pleases. For I am not ignorant that several men have several aims in their Methods of Plants. Physitians rank them according to their faculties and use in Physick. Natural Philosophers have other considerations; some this, and some that.

be at your command and ay to be
at your command 1705

THE SEVENTH BOOK.

Of Animals, or Living Creatures.

Chap. 1. *Of the Sensitive Soul in General.*

AS the Vegetative Faculty is common to all Living things; so in all Living Creatures there is Sense, which is common both to Man and Beast. *By the faculty of Sense Animals are distinguished from Non-animals*, as *Aristotle* hath it *de Juvent. & senect. cap.* 1. and *de sens. et sensil. cap.* 1. Wherefore having treated of Souls in general, and of the Vegetative or growing Soul, and of Plants; we now come to the Sensitive Soul, and to treat of Living Creatures.

The sensitive soul is not the specifick form of any beast:

And here in the first place, as we did before concerning Plants, so we must signifie, That the Sensitive Soul is not the form of any Animal, though void of reason; nor is a Horse a Horse by vertue of its principle of sense; for so a Pike-fish should be an Horse, nor would a Lyon differ from a Dog. Yet is it most manifest, that these Animals differ in their forms, and in their specifical operations depending thereupon. But what those specifick forms are, is not easie to tel, but they are known by their specifical actions. And though many bruit Beasts perform wonderful actions by their specifick forms; yet are they not such as that we should therefore hold them to be Rational, and to partake of understanding. For as *Scaliger*, *Exercitat.* 317. *s.* 5. rightly proves, No living Creature (except Man) performs actions properly Rational. And the holy Scripture attributes Reason to Man alone, as being created after the Image of God, *Ecclus* 17. ver. 16, 17, 18. *Psalm* 32. ver. 9.

Bruits are not rational:

The faculties of the sensitive soul:

But that we may treat of the Sensitive Soul in general; there are three faculties thereof; *the knowing, desiring, and moving faculty.* The knowing comprehends the external and internal senses so called: Appetite follows knowledg: finally to the thing known the living Creature moves. And seeing the knowing faculty goes before the rest, in the first place we must treat thereof, and for the same cause we must first speak of the external Senses. And here you must observe, that the word Sense is taken two waies; somtimes for the Soul it self, or its Faculty; somtimes for the operation which proceeds from the Sensitive Soul, and is called Sensation.

The word sense taken two waies

Now to the performance of Sense these four things must necessarily concur. *First*, The Sensitive Soul: *Secondly*, the Organ: *Thirdly*, the Object: And *Fourthly*, the Medium, which comes between the Organ and the Object. For in the *first place*, Although Sensation is attributed to the whol Animal, Soul and Body; yet the sensitive Soul is the Primary Efficient thereof, and the body is sensitive by means of the soul, which is the sensator or perceiver of things by the senses. For it is the *Entelecheia* or act by which a sensible Animate Body perceives things without it self. And therefore a dead body void of a sensitive soul hath no longer the use of sense. Now the secondary Efficient is the Instruments of Sense, which are also necessarily required to sensation. For although the soul be essentially present in the whol body; yet is it no where the Author of any sense, where it hath no Organ: and although the same Essence of the Soul which is in the Eye, be also in the Foot; yet because in the Foot there are no Instruments either of seeing or of hearing, in the Foot it neither sees nor hears.

Now

Now the Instruments of Sense (to use the words of *Scaliger*, Exercitat. 297. Sect. 3.) are two: The Spirits which have most affinity to the Faculty; and the Members which have most affinity to the sensible Object. For the Spirits are so subtile, that they may be almost reputed immaterial. They receive the imprinted species or representations of Objects. But the Instruments are the conveighers of the Spirits. And although the Organs of the Senses consist of many parts; yet one above the rest is the chief Instrument of Sensation: which *Aristotle* also tels us in these words, 2 *de part. animal. cap.* 1. *All sense is caused by means of the similar parts, because every sense is of some one certain kind of thing, and each sensitive part is accounted capable of some one sensitive kind of things.* *The Organs of the senses.*

Now the Object is that which is perceived by the Sense, viz. The sensible qualities. For although the Objects of the Senses are said to be singular or several things, and corporeal substances; yet substances are not perceived by the sense, as they are substances, but as they are endued with sensible qualities, and contain in them the formal Nature of a sensible Object. For *Peter* (for examples sake) is seen as he is colored; is felt as he is hot, cold, &c. *the Objects*

Now a sensible Object is twofold; of it self, and by accident. That is sensible of it self, which primarily affects the sense, without the intervention of any other thing, as color is perceived by the sight primarily and of it self. But that is accidentally sensible, which is not perceived of it self, but by help of some other thing wherewith it is joyned and coupled. For example sake, when we say, I see a sweet thing, meaning Milk: the whiteness of the Milk is seen only of it self, which is the proper object of the Eye; but the sweetness because joyned with that whiteness, is said to be seen. *Sensible object twofold.*

A thing sensible of it self, is again twofold; Proper and Common. The Proper is that which can be perceived by one sense, and no other; and concerning which no Error can be committed, as color by the sight, sound by the hearing, &c. But the Common is that which is not proper to one sense, but common to divers. And these are five; Magnitude, Figure, Number, Motion, Rest; as *Aristotle* reckons them 2. *de Animal. cap.* 6. *text.* 64. And to these general Heads may al those be referred, which others reckon up; as neerness and farness, which *Scaliger* in *Exercit.* 66. makes a sixt common sensible thing; Scituation, Continuity, Separation, Roughness, and Smoothness, and others which are wont to be reckoned.

Now which way the common sensibles do affect the senses, is controverted amongst Authors, while some say that peculiar species are by them imprinted upon the Senses, and others deny it. But their Opinion is neerer the truth, who hold, That the common Sensibles do present no peculiar species or representations to the senses; but only determine the species or representations of the proper sensibles, and add to them a peculiar manner. For because the Sensitive Qualities are not perceived separated from their subjects, but together with them, the proper enters the sense with the common by one simple species or representation, yet somwhat qualified: and color appears after one fashion in a square Body, after another fashion in a round. But if the common sensibles should send forth proper species, they should also do it without the proper ones. But that they do not do, which appears in transparent things, as the Air, whose figure we do not perceive by its color which is none at al, but by the containing body, rather by imagination than by sense.

Yet we do not say that the common sensible objects are perceived by accident, but by themselves secondarily. For there are three things which belong to a sensible by accident, which do not belong to a common sensible. First, a sensible by accident acts nothing upon the outward sense, whereby it is said to be accidentally discerned, but is only joyned with that which of it self affects the sense. Again, a sensible thing by accident may be perceived of it self, by some peculiar faculty in the Perceiver, whether it be some external or internal sense, or the understanding. Finally, it may easily be perceived by its proper power.

Now seeing al action is performed by mutual touch, and the sensible object is many times far distant from the Organ of sense; the Question is, how the object affects the sense. Hereinal found Philosophers agree, That some quality is sent out of the object unto the sense. Now qualities are twofold, some real or material, others spiritual or intentional; as was said before in *Book* 2. *chap.* 2. and the spiritual are nothing but Pictures and Images of the sensible objects, flowing from them, pure, thin, and free from the concretion of matter; and that there are such spiritual qualities experience it self doth teach us. For in the Summer time, we see the cloaths of such as lie under a Tree painted green with the color of the Tree; and a cloth held beside a Glass ful of Claret, appears red; and other

examples

examples *Scaliger* brings, *Exercit.* 80. *Sect.* 8. and *Exercit.* 298. *Sect.* 3. And in general the same thing is taught by artificial Glasses, which receive the Images even of things remote. And the same is apparent also as to other senses. And that the Nature of sensible spiritual species or representations is quite different from that of material representations, *Leo Hebræus* shews in his *Dialogue de Amore*, *Lib.* 3. by many reasons. The first is, because al other qualities diffuse themselves successively and by degrees through their subject, but light penetrates suddenly and in a moment through a transparent body. Secondly, a quality when it comes changes the natural disposition of the subject; but Light makes no alteration in the transparent body, save that it enlightens the same. Thirdly, other qualites do not extend themselves through an infinite space, but light does. Fourthly, that though the efficient cause of other qualities be removed, yet there remains some impression upon the subject; but the Illuminator being removed, there is no light remaining. Fiftly, other qualities are moved with their subject; but Light is not moved when the Air or Water is moved. Sixtly, many qualities of the same sort in one subject are joyned and mixed together; but many Lights are not jumbled nor confounded, but two Candles make two shadows, three make three shadows, &c.

Whether al the senses do receive only spiritual representations of things?

The first Question therefore in this place is, *Whether all the Senses receive spiritual representations of things.* Some indeed have been of opinion, that spiritual representations are not necessary in al the Senses, but only in the sight; and that al the other senses are wrought upon by material qualities issuing from their objects. But this opinion is false, and al the senses are wrought upon by their objects with spiritual species or representations. And seeing of al the senses feeling is most terrestrial and most drowned in matter, and its object seems to have most affinity with material qualities, if we shal prove that this sense is not wrought upon by real but spiritual qualities, the same wil be proved of al the rest. But heat according to their opinion, acts upon the touch materially; and therefore produces another heat therein; which nevertheless is false. For al the senses are said to perceive the same numerical object whereby they are affected; which observation is true in spiritual qualities. For although an accident or real object does also differ from a spiritual, numerically, if it be considered in it self and according to its own Nature; yet as being the image thereof it resembles and represents the same, it may be termed the same numerically; and the sense perceiving the spiritual image of a thing, is said to perceive the thing it self; but not so, if it perceive a like real quality produced thereby. So he that hath seen the image of *Æneas*, is said to have seen *Æneas*: but he that hath seen *Ascanius* his Son, is never said to have seen *Æneas*. The same appears from the difference betwixt a material and spiritual quality. For since the action of the first qualities is true motion, and is performed in time, and seldom produces in the Patient a quality answering in degrees to its own vertue, by reason of the resistency of contrary qualities; it would follow that sense should be performed in time and leisurely: also that the sense should seldom perceive the true degree of its object, but commonly a lesser. But seeing it is not thus in sense, we must hold that only spiritual species or representations, which have no contrary, are perceived by sense: which opinion also *Aristotle* professes to hold in 2. *de Anima*, *chap.* 12. *text.* 121. Which also is exceeding manifest in most of the tangible qualities, which if they should act materially upon the touch, they should produce therein a real quality like themselves, and the organ of feeling should become hard by feeling an hard thing, soft by feeling a soft thing: whereas these qualities have no such activity; and no such thing is found, either in the Feeling, or any other sense.

Nevertheless you must here observe, that indeed al sensible species or representations of objects are qualities not material but spiritual, and Images or Pictures of the sensible objects flowing from them, as was said in the *place before alleadged*; and that nevertheless there are some differences of them, and that some are drowned in the matter and cannot get out, others diffuse themselves far from the Body from which they arise, being tied to no matter. The lowest of the Senses is feeling, whose object does no where raise it self out of the matter, but being hid in the matter offers it self to the sense. So that nothing is perceived by the touch, but what immediately touches the sensible body. And just so it is with tasts, which never affect the sense of casting at a distance; but whatever affects the tast must immediately touch and affect the tongue. But the visible species or Images of things, imitating the most noble Nature of Light, are free from matter, and at far distances are carried to the sight and affect the same, no body coming between wherein they adhere. After the same manner *Sound* is diffused to a long distance, and penetrates not only the Air, but also Mettals, especially those that are less solid. Betwixt these species or images, viz. The tangible,

tangible, tasts, and visible representations, smels are as it were of a middle nature. For they for the most part, though they are not brought to the organ of smelling without a subject, as the visible species are brought to their organ; yet is there no necessity that the thing smelt should be wholly applied to the nostrils, but smelling things do send forth certain vapors, which are not themselves odors properly to speak (though some Physicians do so think) but the odours are in them; nor can the species or representations of smels be carried without them, into distant Places.

The original of sensible species.

Now as touching the original of the sensible representations, we need not vex our selves, nor introduce any agent sense, to form sensible species out of the objects. Such is the nature of qualities properly sensible, and this power they have, That they can multiply themselves by sending forth their Images; and al forms can multiply themselves, some both really and spiritually, some spiritually only. And if any shal ask, What way they do it? We can answer him no more than if he should ask us how or why Fire heats.

The Mediums of the senses.

Also a Medium is necessary to Sensation. For seeing the senses are only virtually affected by the object, a Medium must needs come betwixt: which also *Aristotle* affirms, 2 *de Anima, cap.* 11. *text.* 114. *We perceive all sensible objects through some Medium:* And in 2. *de Anim. cap.* 9. *t.* 98. *It is common to all, that a thing laid upon the Organ of Sense cannot be discerned.* And al these things must concur, if Sensation be made, and that rightly disposed to; whereof if one be absent, or be not rightly disposed, the Sensation either ceases or is viciated.

Now wherein the Nature of Sensation consists, Authors vary; nor is the Controversie smal, *Whether Sensation be meerly a Passion*, and nothing but the reception of the representation of sensible things? Or whether besides the reception of the species there is any other action of the Soul concurring thereto? I spare to relate al the Opinions of others, which are at large by Authors related and confuted; only I shal set down that which seems to me most true, and this it is: The sensible species, or the object which sends forth the sensible species, is not the agent or active principle of Sensation: for Sensation is the work of the Soul, and that an immanent work, nor can be attributed to any external thing, especially an accident; but it offers and represents to the sense the thing sensible as the immediate object. Nor is Sensation only Reception; which besides other things, is hereby apparent, in that very often, when the sensible species is received in the organ, there is nevertheless no sensation, because the soul intent upon other things does not discern the sensible appearances: but Sensation is also a kind of Action. For Action which is more noble and worthy than Passion is not to be denied to the sensitive faculty, since it belongs to the vegetative faculty, and to Accidents.

Whether there is an active and a passive sense?

Yet we are not to hold two Senses, one active, another passive, really distinct: but the same Soul is said to act and suffer in a different respect. For the Soul inasmuch as it judges and takes cognizance, is so far said to act; but inasmuch as the species is received in the organ, so far the Soul also it self, which is in the organ and informs the same, is said to suffer. Wherefore to receive the sensible species belongs to the Organ; to judg thereof when received belongs to the Soul: yet because the Soul gives the Organ power to receive the species, and is it self the cause of Reception, Passion is also ascribed thereunto.

the manner of sensation:

Sensation is therefore thus made: Spiritual Representations produced by a material object, are received in an animated Organ: being so received the Soul takes cognizance of them and judges of them, and so is said to be sensible: finally, the Action is received in the Organ, and communicated to the whol.

Whether the sense can err about its proper object?

One thing remains yet to be explained, what credit is to be given to the senses, and whether they may err about their proper objects. The Epicureans did attribute so much to the Senses, that they thought we could never be deceived, and held that al which we learn is to be measured by the Rules of the Senses, as *Austin* saith in his Book *de Civitate Dei*, B. 8. *cap.* 7. Whence *Lucretius* in his Fifth Book, conceives that the Sun and Moon, are no bigger than they appear to us. Contrariwise, the Academicks wil give no credit at al to the Senses. That we may know what to think in this point, we must observe these things following: The sense may err three manner of waies: First about the kind or common nature of its object, as taking color for sound, sound for smel. Secondly, in the sort and particular nature of the object, as to take white for black, bitter for sweet. Thirdly, in its application to the object; when it so apprehends some sensible thing, as if it had in it some quality which it hath not indeed; as when the tast judgeth meat to be bitter, which is not so indeed, but seems so, by reason of the bitterness of choler, wherewith the tongue is infected.

Hence therefore thus we conclude the matter: The Sense cannot err about its object, after the

the first manner: for the sight never mistakes Sound for Colour, nor the Ear Smel for Sound: but concerning the common sensibles it may be thus deceived: for it often takes that which is moved to stand stil; and that which is divided into many parts it often judges to be one continued thing. But in the second manner it is not impossible for the sense to be deceived; and that which is blew seems many times far off to be black. Finally, in the Application both of the common and proper Objects it is deceived: so a white thing sending its appearance through a red Glass, is thought to be red also: for then the sight errs not in the colour, but in the application thereof to a wrong subject; and so it is when the Sun is seen through a red Cloud; for it attributes the redness which is in the Cloud unto the Sun. And therefore concerning its proper object, the sense can be deceived only these two latter waies; about the common object all three waies. Howbeit these errors may be avoided, especially in the proper objects, if these conditions be observed. First, That the Organ be rightly constituted, and there be no fault therein. Secondly, That the medium be fitly disposed, and infected with no strange quality. Finally, That that be a fit distance betwixt the Object and the Organ.

Chap. 2. *Touching the Sight.*

Five external Senses. But that we may now come to the external Senses themselves, which in the outer part of the Body do perceive outward things which are present, we acknowledg them to be five in number. For experience shews, that there are no more Organs of Sense, nor can we find more in Man who is the most perfect of Living Creatures, nor in other Creatures any more: and so many do both suffice the use of Living Creatures, and are able to bring the Understanding to the knowledg of Substances. More may be seen touching the sufficiency of the Senses, proved from their End, Efficient, Subject matter, and Object, in *Scaligers Exercit.* 297. *Sect.* 2. 3. 4. Let us now begin with the Sight: For that is the most excellent and noble of all the Senses; seeing it apprehends more things, more excellent and divers, quicker and at a greater distance than the other Senses; *Scaliger Exercit.* 298. *Sect.* 6.

Sight the most excellent Sense.

Its definition. Now *Sight is an external Sense, perceiving and discerning the representations of things visible.* And Vision or Seeing, is the apprehension of visible things by the Soul exercising its sensitive faculty in the Eye. The Organ of seeing is the *Eye*, receiving the visible species or shews of things like a Looking-Glass: Hence is that common saying that *the Eye is the Looking-Glass of nature*, and that a Looking-Glass is the Eye of Art, as *Cælius Rhodiginus* hath it in *Ant. Lect. Lib.* 3. *Cap.* 28. But the chief part of the Organ is the Chrystalline humor, for the sake whereof the other parts of the Eye were by nature ordained.

The Organ of sight

Its Object. The Object of Sight, is that which is visible. Now what that is, we are to consider. Now although many things are said to be seen; yet as to the proper object of sight, the controversie seems to be chiefly of Light and Color: For the best Philosophers do somtimes say, that Light is the first thing visible and that which is visible of it self: and somtimes again, they say the proper and adequate object of the sight is Color, and that all visible things are coloured. Howbeit these two Opinions are not contrary, but if they be rightly explained they include the true opinion concerning the Object of Sight: For indeed the adequate object of sight is colour, and whatsoever is seen under the notion of colour; and therefore light it self inasmuch as it is said to be seen, is comprehended under colour, and is as it were a whiteness. Howbeit, you must observe, it is one thing to be visible, another to be actually seen. All colour is of its own nature actually visible, nor doth it receive its visibility from any external Cause; and though it should never be seen, yet were it visible of its own nature, saies *Scaliger, Exercit.* 325. *Sect.* 4. and that colour which is in the dark, and deep within a thing, is actually colour, yet light is required that it may be actually seen.

What Colour is. Now *Aristotle* defines colour, in his *B. De sens. & sensibl. cap.* 3. *The extremity of that which is transparent in a terminated body*, or *the Extremity of a transparent thing terminated*: which definition that it may be rightly understood, it is to be observed, that colour belongs to al things by means of perspicuity, and that transparency terminated is the Subject of colours. For transparency being condensed, so that it can be no longer seen thorough, nor transmit the Images of other things, becomes coloured, and is said to be terminated: for it prescribes bounds and limits to the Sight, and is an hinderance that other things cannot be seen which lie betwixt it and the sight; for although that same colour also which is in the middle and depth of a thing, is also colour: yet he seems rather to have defined that which

is

is actually seen, and is in the Surface. For Colour is not the Surface as some ill expound *Aristotle*, but in the Surface: and the extremity of a body as a body is one thing, and the extremity of a diaphanous or transparent body considered as such is another. Now the term or bound of a Diaphanous or transparent body is where it becomes dark.

Colour therfore hath its Original from the termination of that which is transparent: And that is two waies; first only by condensation of the transparent body, without the admixture of another body, after which manner the Stars come to be seen. Again Colour is made by the mixture of a dark body with a transparent. So Fire which is of it self transparent, if it be mixed with exhalations and fumes, appears of a red colour; and the same comes to pass in the Air and Water: for these three Elements are transparent, though in a various degree; for Fire is most of al transparent; after that the Air; Water seems to have some darkness in comparison; but the Earth is absolutely dark. And therefore by the mixture of the earthy parts with the other Elements sundry colours arise. But in the first place, that which is transparent becomes white; and therfore that which is transparent, light, and whiteness, are almost of the same nature: in like manner, Intransparency, Darkness, and Blackness are also of kin. And these are the first, simple and extream colours, which do also proceed from the first simple Bodies, and all other colours consist of a mixture of these; al the sorts whereof to reckon up in this place would be too tedious; touching which *Scaliger* hath many excellent things in his 325. *Exercitation.*

Now apparent colours are made of the Species of real colours mingled with others. And therefore when the Sun's light is mingled with the colour of Clouds, various colors do result therefrom. Therfore we conclude that colour is visible, but that illuminated or shining colour is only actually seen. *Apparent Colours how made*

Whence also a Cause may be rendred why some things are not only seen themselves, but make others to be seen; and some things can be seen themselves, but cannot make other things to be seen: and others again can neither be seen themselves, nor make others to be seen. For some things have an inbred light proper to themselves; some only an adventitious or borrowed light. Such as have an inbred light can be seen without the help of other things. And such as have it plentiful and potent, as the Sun and Fire, do also make other things visible; but such as have little light in them, and so little as can only render them visible, and that but in the Night, do not at al help other things to be seen; such as are some rotten woods, Glow-Worms, and such like: but those things that have no innate light, can neither make other things visible, nor are they visible themselves, unless they be enlightened by some other thing.

Now because Light is necessary to Sight, it is worth our enquiry how it concurs thereto. Some hold, that it is only required to illuminate the object and medium, others that it is necessary also to inlighten the Organ. As to the object, it is altogether necessary that it be illuminated, that it may be actually seen; and that appears by experience. For although the whol Air which is about the Party seeing be illuminated, yet if that which is about the colour be not illuminated, the colour cannot be seen: for the colours of themselves if they be not illustrated by light, do remain sluggish as it were, so that they cannot produce an Image of themselves; and light is the act of colour, not to make it to be, but to make it visible, as *Scaliger* saies, *Exercit.* 75. *S.* 7. Also for the Medium light is requisite: yet is it not necessary that the whol be illuminated, but only that part which is about the thing visible: and so light seems not necessary to the medium as a medium; but only in respect of the visible object therein residing. For even when we are in the dark we see those things that are in an illuminated Medium; and in the deepest wels, where no light reacheth, we see the Stars even in the day time. *How light concurs to sight.*

As to the Organ, we avouch with *Aristotle, de sens. & sensibil. Cap.* 3. *that as without, so within, there is no seeing without light*: howbeit we hold that it is rather an inward and inbred than an external light, which the Eyes of many Creatures that shine in the night, do witness. But that an Eye which is in the thickest darkness can be illuminated and illustrated by a light so weak, as to be able to inlighten things close by it (as for example that which shines from rotten wood) is improbable: As also it seems impossible that a light and colour smal and weak, far distant from the Eye, can any waies inlighten the whole Air as far as to the Eye.

And because that *Light* is altogether necessary to sight, it is enquired, *whether it also be seen.* We answer: That Light while it is in a transparent medium is not seen, as that *which*, but as that *wherewith*; and that it is not seen of it self, but *by accident*; because it makes colours to be actually seen: and when we see colour, we judg that the Air is illuminated. *Whether Light it self be seen*

The Medium of sight.

But the Medium of Sight is that which is *transparent*; and that which is seen is alwaies more darksom than the Medium. Hence we see water in the Air, and the same thing colored is seen in pure cleer water, and hid in that which is troubled. And therefore a thing colored may also be the Medium of Sight, provided it be not quite dark, but more transparent than the visible object. So we see smal creatures incloſed in Amber.

whether sight be caused by receiving in, or sending forth.

The Manner of Sight remains yet to be explained, concerning which there are no smal controversies amongst the Ancients. For though herein al consent, That to cause sight the object must of necessity be joyned to the organ; yet how that is done they are not al agreed. The Platonists (for as for *Plato* himself, some wil have him to be of one Opinion, and some of another; and *Scaliger* in *Exercitat.* 325. *Sect.* 5. cites places out of his *Timæus* and *Meno*, whereby he endeavors to prove, That *Plato* conceived sight to be caused by species flowing from the Object to the Eye) very many skil'd in the Opticks, and al ancient Philosophers in a manner until *Aristotle*, held that the Optick spirits and raies went out of the Eye to the Object, and laid hold of the same.

But this Opinion is false and corrected by *Aristotle*, so that those Ancients are not so much to be blamed, as they are to be chastised who contrary to the judgment of that wise Man, do stil follow those toyes. For Sight as al other Senses, is an immanent action, and therfore it must be performed in the Eyes, and not without. And seeing every agent which acts upon another thing without it self does not receive in it self the end and fruit of its action (as the operation of heating is not received in the agent but the Patient) the fruit also of sight if it were caused by sending forth of raies, would be in the thing seen, and not in the Seer; which is absurd. For the end of sight in a Living Creature is the accommodation of its life: but in Man besides that, also the knowledg of Nature, comprehension of God, and Happiness. Finally, What can that be, which out of so smal an Eye-bal can be sent so suddenly to so many things as we behold, so distant? A corporeal substance, such as are the Optick spirits, cannot be shed forth in so great plenty. For there is nothing that can suffice to repair so many spirits; nor can it be moved in an instant from the Eye so far as to the Heavens: Nor can any quality of it self perform the same; but if it should do this, the soul must needs be in it. But the subject of the soul is a substance, not an accident. Yea, in general, whatever you hold goes forth and causes sight, it must do it by means of the soul. Whence it would follow, that the Air hath in it not only one soul, but the souls of many living Creatures. And those very arguments and many more which are brought by *Zabarella Lib.* 2. *de Visu, cap.* 4. 5. do make against that Opinion of *Galen* and others, who hold, That the sight goes out a certain distance, and is united with the image of the visible object, and that so sight is caused.

the true manner of sight.

Let us therefore hold with *Aristotle*, That sight is caused by the reception of visible images into the Eyes; and that as from every point of a lightsom body into every point of a transparent Medium Light is propagated: so from every part of a colored body, an Image thereof is sent into a transparent Medium, by a right line, and received into the Eye, and discerned by the sight. For even the images received do appear within the apple of the Eye; and an excellent visible object hurts the sight; and the Eye is made of so many parts, for this Receptions sake.

Chap. 3. *Of the Hearing.*

the definition of hearing.

AFter *Sight* we rank *Hearing*; for it (after Sight) is the most excellent Sense, and seems to contend therewith in point of nobility. Now the Hearing is an external sense, which by help of the Ear perceives audible things, viz. Sounds: for the object of Hearing is Sound. Now Sound is a quality arising from the Air or Water being smitten and broken by the vehement and sudden concussion of solid bodies.

What sound is.

How sound is generated.

To the generation of Sound three Bodies are necessary: two of which mutually strike one another, or at least one performing the office of two, in two parts. Now these bodies ought to be solid, that they may gather and condense the Air, and not having many pores. Hence Spunges, and locks or fardles of wool knockt together, do cause no sound; because being ful of many pores, the smitten Air is received by them, and so it is not broken. Besides two solid bodies, a third thing is required, which may be intercepted betwixt those two solid bodies and broken. And this is that which also Fishes hear.

the Medium of hearing.

The Mediums which receive sound are the Air and the Water. They commonly hold, that a certain inbred air of the Ear is the chief organ of Hearing. Contrariwise other later Authors,

Authors, since the Organ of a sense ought to be a similar part animated, do reject this Air: and hold the principal instrument of Hearing to be a certain Nerve spred out in the Ear. And truly the former Opinion is not so allowable as this, unless it be explained as *Capivaccius* explains it; who teaches, that as the innate heat of the Eye is luminous or lightful; so the innate heat of the Ear is Aerial, so that it may be affected by sound, and is commonly called, complanted Air, that is, Air bred in the Ear from the first formation; but that it is not included in any peculiar Cavity, but ingrafted and implanted in the expanded Nerve.

How Eccho is caused.

Here we must not pass over the Eccho, which is a reciprocal and reflected sound from a smooth and hollow place. For as Light and visible Images lighting upon a smooth and polished body are reflected: so sounds, if they light on a smooth, even, and hollow body, whereon they are not broken, they are reflected. And as in general, that sound may be heard, it is not necessary that al the air from the place where the sound is first caused, should be continually broken, as far as to the Ears; but it is enough if the image thereof be propagated so far; even so an Eccho is not bred by a new breaking of the Air, for so this reciprocal sound would not be articulated: but only the image of the former sound rebounding back to us. Nor may a word be only once reflected, but divers times, viz. If the voyce beaten back do light upon other hollow places, one after another. So the seven Cyzician Towers did multiply words received by them with a manifold Eccho. And *Pliny* relates, how in the Porch of *Olympia*, which they therefore termed *Heptaphonon*, the same word was seven times repeated; *Nat. Hist. Lib.* 36. *cap.* 15. And *Lucretius* in his Fourth Book, thus writes:

I've known some Ecchoes, if you spake a word,
Would six or seven times back the same afford.

Chap. 4. *Of the Smelling.*

the Definition of Smelling.

THe *Smelling* follows after the Sight and Hearing in point of Excellency, which is an external sense perceiving smels, by help of the Nose or mamillary processes therein. For

Its object.

the object thereof is a scent or savor.

the Nature of the Smelling.

Now touching the Nature of the Smel, the vulgar Doctrine is, that it is a quality arising in mixt bodies, from a dry savory thing by the Heat mingled with moisture. For they say smel and tast are so of kin, that al things which have tast have also smel, and every thing that hath no tast, hath no smel neither. Hence mixt things only have smels, and not the Elements, which also have no tast: for neither have al mixt things smels, but those only which have tasts. For stones have no smel, which are also void of tast; but woods, and other things which have tasts, have also smels. But herein nevertheless smels and tasts differ, in that drines prevails in smels, moisture in tasts. Hence Nitre hath a stronger smel than Salt, and Salt is moister than Nitre; because in Nitre there is more drines, in Salt more moisture; and things that smel, if they are over moistened they loose their smel. For the same cause, if after a drought the Rain fals, at first a certain smel is perceived; because the dry is mingled with the moist: but the smel lasts only so long as until the drines overcomes the moisture; but if the rain continue so long, that the drines is vanquished by the Moisture, the smel also ceases.

the Efficient cause of smel.

They hold the efficient cause of smels as of al works in mixt bodies to be heat, which in due measure and manner mixes the moist with the dry. And hence they give the cause why most things that have smel, smel strongest when they are hot; why some things smel not at al unless they be heated; and why most things smel more in the day than in the night, in the Winter than in the Summer. For when in the mixt body moisture does very much abound, or drines is not rightly mixed with the moisture; there arises either no smel, or one which is imperfect. And that therefore there is need of heat, which may either consume the overmuch moisture, or mingle the same with the dry parts after a due manner.

But seeing what *Scaliger* saith of Tasts, *Exercit.* 279. *Sect.* 4 That Tast no more arises from the first Qualities than Laughter, is most true of smel: they labor in vain, who endeavor to draw smels from the first Qualities; since they are not in the power of the first Qualities, and we must have recourse to nearer principles. And the Chymists do far more probably deduce odors from Sulphur, and hold that Sulphur is the prime subject of

ſmels; of which we have ſpoke elſwhere in our Treatiſe of *the Conſent and Diſſent of the Chymiſts with the Ariſtoteleans and the Galeniſts, chap.* 11.

Differences of Odors. The differences of Smels are little known; but becauſe the Taſt and Smel are of kin, and moſt ſmels have much affinity to taſts, the names of taſts are alſo given to ſmels. Now the Taſts do follow the Nouriſhment, which is examined thereby by Creatures that eat the ſame; and therefore theſe ſavors of themſelves bring no pleaſure or diſpleaſure, but only by accident, as they are ſigns of good or bad nouriſhment. Hence the greatie ſmel of roaſt-meat is delightful to the hungry. Theſe odours are exquiſitely perceived by Bruits, and therein they excel Man-kind.

Yet there is alſo another kind of ſmels which does not follow the Aliment, but is of it ſelf pleaſant or unpleaſant, as the ſmel of Spices and many other things. And with theſe ſmels, as alſo the beauty of colors, Men are either only or chiefly affected: and other Living Creatures how exquiſitely ſoever they ſmel other ſcents, yet herein they are far outgone by Man-kind; ſo that either they take no delight from ſweet ſmels, or if they do, it is very imperfect and maimed, and agrees but to a few of them. Of which ſee *Scaliger* in *Exercit.* 303. *S.* 2.

From what hath been ſaid is not hard to judg what is the true object of ſmelling, and after what manner ſmels are perceived by the ſenſe of ſmelling. That Odours are the object of ſmelling was ſaid before, nor does any man deny it: but how that is to be underſtood, is not ſo manifeſt. *Heraclitus* (as *Ariſtotle* ſaies) *de ſenſ. & ſenſibil. cap.* 5. Many ancient Philoſophers, *Galen* and very many Phyſitians are of Opinion, That the ſenſe of ſmelling is not only affected by ſome ſpiritual image and repreſentation, but that a certain corporeal, aerial, thin exhalation does flow out of ſmelling things, and is perceived by the ſenſe. Contrariwiſe, the greateſt part of Peripateticks are of opinion, that a naked image of the ſmel does ſpiritually flow from the odorous body, as an image from a thing viſible, and is carried to the organ of ſmel, and thereby perceived.

Odors are not ſubſtances. The latter Opinion ſeems truer to us, provided it be rightly explained: yet that there is ſome truth in the former cannot be denied, though in ſome part it ſwerve from truth. For in the firſt place, this muſt of neceſſity be allowed, That odours are not ſubſtances, nor any thing corporeal: For the ſenſes do not perceive ſubſtances, but only their accidents. Again, this alſo hath been ſhewn before; That no ſenſe is affected by a real or material quality, but only by its repreſentation, or a ſpiritual and intentional quality as they cal it. And therefore we muſt alſo hold the ſame as to the ſenſe of ſmelling, that the ſaid ſenſe perceives nothing corporeal, nor yet any real quality, but only the Image thereof.

The ſmelling perceives only an image.

Nor muſt we in the next place deny that ſomwhat does flow from and exhale out of ſuch things as ſmel, and is carried in the Air. For dayly experience teaches, That odoriferous exhalations do ſundry waies affect the Brain, and very often change the temper thereof, and ſomtimes qualifie and rectifie the ſame, other whiles cauſe heavineſs of head, as *Hippocrates* hath it in his 5. Sect. of Aphoriſms, Aph. 28. Yea, and this comes not to paſs in the Brain only, but many times by odorous exhalations we perceive our Noſtrils, Eyes, and Face to be gnawn as it were, and pained. Moreover, we ſee that odoriferous things by little and little do for the moſt part waſt and conſume away. And when an odoriferous thing is taken away, the ſmel remains many times a long while after in the Air, which cannot be done by the images alone, which do not remain when the object is removed. Al which things teach, that oftentimes there flows from odorous bodies a certain corporeal exhalation, which hath a power of heating, cooling, and doing other things, which cannot be effected by bare ſpecies and images. This therefore we grant, That from many things a certain odoriferous vapor exhales, and that corporeal ſavory vapors do flow from things that have ſmel: but yet we avouch that a ſpiritual ſpecies is required and preſuppoſed to cauſe the ſenſe of ſmelling. But whether or no both are alwaies neceſſary, and whether the ſpecies of the Odor, which is properly perceived by the ſenſe of ſmelling, is alwaies joyned with ſome corporeal ſubject or vapor, without which it cannot be carried to the Organ of Smelling, is yet in doubt, and this is the main hinge of the Controverſie.

Whether the ſpecies of ſmel need alwaies the carriage of a vapor.

We have ſpoke before in *cap.* 1. of the difference of ſenſible ſpecies, and have granted that odours for the moſt part are indeed carried to the ſmel with a corporeal ſubſtance: but we deny that this is alwaies neceſſary, and hold that the exhalation which comes from the odorous body does not alwaies reach ſo far as to the Noſtrils, yea, and that ſomtimes no ſuch thing comes from the odorous body, and that the ſmelling is cauſed by ſpiritual qualities and images, of the ſavors proceeding from the odoriferous body to the organ of ſmelling. For if that ſame vaporous exhalation ſhould be alwaies joyned with ſmels as their carrier,

Fiſhes

Fishes could perceive no smels in the water, nor could be allured thereby to seek the Bait: For since the nature of odoriferous exhalations does consist in a dry subject elaborated by heat, and the nature of exhalations is such as to ascend upwards, how should those exhalations come to the bottom of the water? or if they should come thither, how wil they retain their driness and the integrity of their nature in the water, since odoriferous things when wet are wont to lose their smel? Moreover, how can there be so great and so long an efflux of vapors from odoriferous things, as may suffice to fil most large spaces? The whol odoriferous things verily which are but smal many times, if they were al turned into vapors, could not fil such distances. Yea, and we see many things do smel a very long time together, and yet are not at al consumed or wasted.

whether Odours nourish?

From the Premises also that Question may be explained; Whether Odors can nourish a man? For seeing the nourishment of a body ought to be a body, and we are nourished with the same things whereof we consist; and odors are qualities; we hold that they have no power to nourish. And whereas it is said that sick persons are many times refreshed with smels, and that *Democritus* for his sisters sake (whom he would not draw from the Feast of the Thesmophorist) did prolong his life three daies only by smelling to hot Bread; that must not be attributed to smels, but to odoriferous vapors exhaling from the Bread, and re-creating the spirits. Nor is that true nutrition which is made by apposition of a like substance, viz. Of Blood elaborated in the Liver; but only a certain cheering of the Spirits.

what is the Organ of the smell?

As to the Organ of Smelling, though al agree herein, that the Nostrils are the Instrument of smelling; yet it is controverted betwixt the Physitians and Peripateticks, what is the chief Organ of smelling. For the most Peripateticks do hold the proper Organ of Smelling to be the Nerves dilated in the Nostrils. *Galen* holds smel to be produced in the foremost Ventricles of the Brain, in 8. *de usu partium, cap.* 6. *de olfactus Instrumentis, cap.* 4. Other Physitians say, That from the Brain neer the Cavity of the Eyes, two Channels are derived to the bored bones of the Nose, whose ends seem like teats (whence they are called the mammillary or teat-like productions) and that in them as the proper instrument odors are discerned. Which Opinion is most agreeable to truth, and the greatest part of the best Physitians do follow the same. For the Brain is not the proper Organ of any external sense, but the common, as supplying spirits into the organs of the external senses, As to the Nostrils, true indeed it is, That odors are perceived by them alone, and that these are the only waies Nature hath appointed to carry smels to the Organ of Smelling: yet the perception and judgment of Odors is not in them, but in those mammillary or Teat-like productions, which are placed before the Ventricles of the Brain, as the examiners of smels. For if we attribute the faculty of perceiving Odors to the Nostrils alone, and the Nerves in them dilated, what should hinder us from smelling, so long as we have our Nostrils? Yet Experience shews, That when those processes are obstructed, as is wont to happen in the *Coryza*, the Smelling is either abated or quite taken away, without any fault in the Nostrils. Moreover, if Smelling were made in the Nostrils, we should perceive smels without breathing; whereas nevertheless we find by dayly experience, that the most odoriferous things being put to our Nose, we smel nothing unless we draw our breath; the reason whereof is, because those mammillary processes are placed within the Skul, so that smels cannot come thereto save by attraction of the Air.

The Medium of smelling.

The Medium through which Odors are discerned, is the Air and Water. As to the Air there is no doubt. But that in the Waters also smels are discerned by Fishes, this is an argument, that Fishes are allured by the smel of Baits; which *Aristotle* proves by many examples, in his Book *de Histor. Animal. Lib* 4. *cap.* 8. And so much may suffice to have said of the Sense of Smelling.

Chap. 5. *Of the Tasting*

The Definition of tasting: wherein tast differs from feeling:

THe Taste is an external Sense, by help of the Tongue discerning savors. Which sense though some confound with feeling, and make it only to be a sort of Touch: yet they are questionless in an error, and we must acknowledg the Taste to be a peculiar Sense. For although the touch is sometimes generally taken for a sensitive power, which takes cognizance of an object, not removed but applied to the Organ (and in this manner the Taste may be called a kind of feeling, and so it is by *Aristotle* in that sence called) for it does not perceive things distant as the sight does colors, but only savors applied to the Tongue: yet that

that signification is not so proper; and the Question is, whether the Touch be the same Sense, with that power that perceives Tangible Objects: which is denied. For they differ both in the Object and Organ: for the Object of the touch is tangible Qualities, but of the Tast Savors: and the tast may be lost in the Tongue, while the Sense of Touching remains entire. And therefore their Organs are quite different; and though in the Tongue there be Touch, yet where ever there is Touch there is not Tast; but only in the Tongue; whose thin soft and spungy flesh, the like whereof is not in the whol Body, is the proper Instrument of Tasting.

The Object of Tasting is Savor. Touching the nature whereof, we pass over the Opinions of the Ancients, *Empedocles*, *Democritus*, *Leucippus*, and *Anaxagoras*. The Peripateticks do thus teach concerning Savor. No simple Body hath any savor or tast, it being only an adjunct of mixt bodies, and thereto three things are requisite: an earthy drineſs, a watry moisture, and Heat which is the Author of all operations in mixt bodies: Of which we have every where frequent signs and tokens: For Water which of it self is tastless, if it be strained through some earthy dry substance, it becomes savory, as appears in Fountains, which receive divers tasts from the parts of the Earth through which they flow: and the water of Lye is bitter, because it is strained through Ashes. Howbeit the Nature of tast consists more in moist parts than in dry: and it is a quality affecting the tast, arising in mixt bodies from the permistion of a watry moisture with a dry earthiness. And seeing the mixture of moisture with drineſs is various; and the watry moisture joyned with earthy drineſs which is the subject of Tasts is various, somtimes thicker, somtimes thinner, and the Heat which is the Cause of tasts is somtimes stronger, otherwhiles weaker, hence also sundry tasts do arise which are severally reckoned up, by several Men. Most do acknowledg chiefly seven simple tasts or savors; and from their commixture others may arise, or at least they may be referred to them: Sweet, Sour, Harsh, Rough, Salt, Bitter, Biting. These tasts may be considered two manner of waies, either in respect to the first Qualities Heat and Cold, or to the sense of Tasting which they affect.

Kinds of tasts.

The former way they are chiefly considered by Physitians, and they serve them to know the Qualities of medicaments by, and are divided into Hot and Cold. Into three Cold, Sour, Harsh, Rough; three Hot in excess, the Biting, Salt, and bitter, and one moderately hot, *viz.* Sweet. And thus with Physitians the Harsh and Biting tasts are the extream tasts, the former the Coldest, the latter the Hottest of all others. The Philosopher considers them rather after the latter manner, and takes not their difference from the tangible Qualities, but from the Effect whereby they work upon the tast: and thus because that tast which is most contrary to sweet is the bitter Tast, and the one is most pleasant, the other most unpleasant: therefore these two are by Philosophers counted the extream tasts, the rest are intermediate.

Sweet tast

The sweet Tast therefore is most pleasing to the Palat, arising from the mixture of a watry moisture with an earthy drineſs, made commonly by a moderate heat. Such is in Bread, Milk, ripe Grapes, Figs, Licoris, Sugar, Honey. Although in these also some degrees may be observed in heat, for some are hotter than other some; and those that come neerest a mediocrity are most fit to nourish a man.

A tart tast

An acid sharp tast consists in a matter thin and subtile, and arises from a weak heat, or because in the mixture there are many watry parts which cannot be overcome by the Heat, or because out of the mixt body the hottest parts, especially those that are most pure, namely the Aery, are exhaled. Such a tast is in Vinegar, Sorrel, Juyce of Lemons.

An harsh tast

An harsh tast consists in a matter indifferently thick, and ariseth from a greater degree of cold, and a weaker heat than the Sour.

A rough tast

If the matter be yet thicker and the Heat weaker, and the Cold stronger, it causes a rough tast, which is in some unripe Apples, in Acorns, and Galls.

Salt tast

A Salt Tast is in an earthy matter, not subtile, but rather thick and earthy: and it arises from an heat exceeding mediocrity. And therefore the first subject of a Salt tast is an earthy drineſs, through which a watry moisture is strained, adust, so that little of the watry humor remains therein: yet from a smal portion thereof a great quantity of Water may be infected.

A bitter tast

In a bitter tast Heat is commonly yet greater, and its matter drier and more earthy.

The biting tast

Finally from the greatest heat arises the biting Tast, and it consists in a subtile matter: and therefore things so tasted have a faculty of burning, penetrating, and drying; such is in Pepper, Ginger, Garlick, Onions.

Thus I say, the Peripateticks and the Galenists endeavor to deduce the kinds of tasts from the first Qualities. But as was said before from the *Exercit.* 297. *S.* 4. of *Scaliger*, Tasts

do

do no more arise from the first Qualities than Laughter. And what lost labor it is to endeavor to give a reason of Tasts from the first Qualities alone, is learnedly shewn by *L. Grillus* in a peculiar Book *de Sapore amaro & dulci.* The Chymists more probably draw tasts from Salts, and teach that Salt is the first subject of Tasts, and that from the several kinds of Salts proceed the sundry kinds of Tasts, of which elswhere in my *Tract. de Consens. et dissens. Chym. cum Aristotelicis & Galen Cap.* 11.

The Medium of taste.

There is no external Medium required to tast, but if the tast of any thing is to be discerned, it must be applied to the Tongue. Yet the Internal medium is a spungy or rather porous Skin drawn over the Tongue, and the moisture of Spittle. For to this part the Tast is first communicated, whose representation is afterwards carried through the pores of the Tongue into the flesh thereof, and is there perceived by the Soul exercising the sense of Tasting. *And so much for the Tast.*

Chap. 6. *Of the Touch.*

The touch.

THe last external Sense and the most common of all the rest, is the Touch, which perceives tangible Qualities. Touching this sense, no smal Questions are wont to be agitated. And in the first place they are wont to enquire; whether the Touch be only one Sense in number,; or whether there be one power of Feeling, as there is one of Seeing, one of Hearing, one of Smelling, one of Tasting, or more. *Aristotle* moves this Question in 2. *de Anima Cap.* 11. and brings this reason of doubting. There is one Sense of one first Contrariety: and one Sense hath one proper Object, to which all that it perceives may be referred: But the Touch seems not to have one common Object, but many: for it perceives Hot, Cold, Dry, Moist, Heavy, Light; Hard, Soft; Clammy, Brittle; Rough, Smooth, Thick, Thin; which cannot be reduced to one common kind, or one common notion, according to which they are perceived by the Touch. Many being perswaded by this reason, have held divers Tasts; some two, one to perceive Hot and Cold; another to perceive Moist and Dry; others three; the two aforesaid, to which they attribute also Hard and Soft, Rough and Smooth; and a third to perceive Lightness and Heavines: others hold that there are so many senses of Feeling, as there are differences and contrarieties of tangible Qualities. Others have yet added more senses of touching, to perceive Pain, Pleasure, Venery, Hunger, Thirst. Others contrariwise do hold that there is one only Touch or Sense of Feeling, which though it hath divers Objects, yet it perceives them all under some common notion; just as the Sight perceives White, Black, Red, Yellow, Green, under the common notion of Colour.

Whether there be but one Sense of Touching.

Now although it be hard to compose this Controversie, and most learned men have held, that no certainty can be determined in this Point: yet very many have thought it most probable that there is only one faculty of touching. And several men have severally endeavored to reduce the sundry differences of tangible Objects to some one common Nature. For some say, though the Object of Feeling be manifold: yet is it contained under one common kind, though it want a name. And that it is a Quality that primarily follows a body as a body, or which immediately depends upon sublunary Bodies, and necessarily accompanies the forms of the Elements, and of the bodies of them compounded. Others also attribute to tangible Qualities one manner of affecting the touch, and that they say to be a changing of the complexion of the first Qualities, and hence the sense of feeling is said to be a sense of the temperament: and that therefore the first Qualities are the chief object of feeling, and the rest pertain thereto after a secondary manner; and such things as cannot be reduced to these, are common sensible objects, which constitute no peculiar sense. Finally, others distinguish betwixt the external sensibles, such as are Hot, Cold, Moist, Dry, Hard, Soft, &c. and betwixt the internal, which are perceived in the Feeler, as Pain, Pleasure, Hunger, Thirst. They conceive the external are perceived by one only sense. For although they are many, yet they may be reduced to one common notion: and indeed we find by experience, that he who can by touch perceive one of those contrarieties, he can also feel the other by the same part: contrariwise he that cannot feel one of them, cannot feel the other. But they hold that Hunger, Thirst, Pleasure, Pain Corporeal, are discerned by another power; seeing these powers and acts are so separated, that in the part wherein the external are perceived, Hunger, Thirst, and such like are not perceived.

As

the Organ of feeling: As to the Organ, it is not so easie to find it in this Sense as in the rest, and there are very great Controversies hereabouts, not only among the ancient Writers, but the later also: for some hold the Flesh, others the Skin, others some other thing to be the said Organ: but we conceive the true Organ of Feeling is a Membrane. For where-ever there is a Membrane, there is also Feeling; and where there is no Membrane, there is no Feeling. Hence the Brain feels not save by means of the Membranes; and the Membrane which compasses the bones being removed, the bones themselves have no more feeling. Moreover, because the Touch is a Sense most common, and is given to Living Creatures in their whol Bodies, to avoid the external injuries, therefore its Organ was to be spread al the body over, and that such an one as should have no other office in the Body: for every Sense hath its proper Organ. But if we consider al things in the whol Body, al have peculiar offices save a Membrane: the Nerves carry animal Spirit, the Veins Blood, and other parts (as is known) have other uses. And therefore this office cannot be assigned to them; and there remains only the Membranes which are both similar parts, and have no other use, but are given to Living Creatures only, that they might be the immediate Instrument of Feeling.

Chap. 7 *Of the Internal Senses.*

HAving explained the External Senses, we come now to the Internal, which are busied about matters sensible presented by the external Senses. For this is the chief difference betwixt the internal and external Senses, That the external are immediately affected by an external object, whence also they are called External: But the internal are not moved by the external sensible object immediately, but they are moved by the external Senses; and therefore they are called Internal. But as touching the Number of the internal Senses the Controversie is so great (as may be seen in *Francisc. Piccolhomineus, de sens. intern. cap.* 3, 4, 5, 6, 7. Francisc. Toletus *in Lib.* 3. *de Anima, cap.* 3. *Qu.* 6. Collegium Conimbricense *in Lib.* 3. *de Anima, cap.* 3. *quest.* 1. *Artic.* 1, 2, 3.) that it is a hard matter for a man to disintangle himself, being herein engaged. We retain the common Opinion, which is the most probable, and acknowledg three internal Senses, from the diversity of Offices and Works by them performed, viz. Common Sense, Phantasie or Imagination, and Memory.

the internal senses are three:

Common sense We must by al means hold a common Sense: For since Animals do know the differences betwixt the proper objects of sundry Senses; and the external Senses cannot perform this Office; since each of them knows only its own peculiar object: of necessity we must hold there is some internal Sense, which apprehends the objects of al the external senses (whence also 'tis called the common Sense) and discerns one from another, and does know that color differs from sound, sound from smel, smel from tast, tast from what is hot, that which is hot from that which is black, &c. For the chief Offices of the common Sense are, to perceive the objects of al the external Senses by help of the said Senses; to know and perceive that we are sensible of this or that; to know the difference betwixt the divers objects of the Senses; to judg the privation and absence of the objects, as of darkness, silence, &c. to move the Phantasie and to offer Images and representations of things thereunto. This Sense therefore is as it were the middle stickler betwixt the Senses internal and external, and receives images from the external, and communicates them to the rest of the internal. Whence it is not unfitly compared to the Centre of the Circle, wherein five Lines concur and meet together.

Phantasie: Besides the common Sense the Phansie must also be added. For since in perfect living Creatures it is not only necessary to apprehend things present, but also diligently to consider that which is no longer present, that they may be incited either to seek or shun the same; among the internal Senses we must also reckon Phansie, which may retain the sensible representations perceived by the common Sense, or framed by it self, and diligently examine the same. And although it be altogether necessary, that the Phansie be first moved by the external Sense; yet after it hath once perceived the object, and hath committed the image thereof to the memory, afterwards even in the absence of the external object, it can as often as it list review and imagine over again the same image. But of necessity the Fansie must first be moved by the external Sense, and we can imagine nothing which we had not before perceived by the external Senses. And though we may imagine a Mountain of Gold and the Monster called a *Chimæra*, which we have never totally seen; yet we have seen them

them by piece-meal; and except we had seen Gold and a Mountain we could not imagine a Golden Mountain: so unless we had seen a Lyon, a Goat, and a Dragon, we could not imagine the *Chimæra* or Monster compounded of al those Beasts.

the Memory:

Finally, among the internal Senses the Memory is to be reckoned: For because the Fansie without knowledg cannot receive the species or representations of things; and it cannot take cognizance of many things at once: therefore there is need of a faculty, which it self does not take cognizance, yet is subservient to cognition, that is to say, which may receive divers sensible representations known by the Fansie, and reserve the same, and suggest and present the same thereto again when need is. Also Experience it self does witness, that in diseases of the inner Senses, one of them may be lost and destroyed or depraved, the other remaining safe and sound: and in Feavers it often happens, that the Patients their Memory being sound, do imagine that there are Fidlers and other things in their Chambers, and seek to pick flocks and feathers or straws where there are none: and such like examples are frequent in the Writings of Physitians: which is an argument that the Fancy is a faculty distinct from the Memory.

A twofold Memory.

Now some do make a twofold Memory, Sensitive and Intellective: but it is enough to say that the Memory is a Faculty common to Man and Beast. But after what manner the act of remembring is performed, is a very obscure point. They commonly hold that sensible objects do imprint certain images on the Brain or Organ of Sense, even as in Wax the Picture of the Seal is imprinted, which remains after the Seal is taken away. Whence they say, such as have an hard and dry brain have an hard apprehension of things, but retain them longer; but they that have it moist and soft, do easily receive, but cannot so long and faithfully retain.

But it is (peradventure) more advised to confess that in this point we are in the dark, than to hold such things; especially if you weigh that which *Scaliger* hath, in his 397. *Exercit. Sect.* 28. against this Opinion. For if Memory be made after this manner, since it is in a manner Infinite; in what spaces can so many Images be retained? in what seats can they be so disposed and ordered, that we may draw out, rank, direct, every one apart, and al together. Now why a dry Brain is more apt for Memory, *Scaliger* brings a new cause in the place forecited, which may there be seen.

Two acts of Memory.

1 Memory.

2 Remembrance.

Now there are two acts of Memory, or of the remembring Faculty: the one of which is called by the name of the Faculty, Memory; the other Remembrance. Memory is defined to be the iterated apprehension of a thing formerly known; or a repetition of what hath been formerly perceived by the Senses, just as it was perceived: For examples sake, if I am asked what's the name of the King of *France*, I can suddenly recite the same, as I have sometimes heard it named. But Remembrance is to go back from one or two things retained in the Memory, til we cal to mind somwhat which we had as it were forgotten: as if a man having forgotten a name, should go over al the Letters of the Alphabet, and joyn every Consonant to each Vowel once, and so make single syllables, til meeting with the first syllable thereof, he come thereby to cal to mind the whol name which he had forgotten. And therefore more things are required to Remembrance than to Memory; and Memory is common to the Bruits, but not Remembrance: For to Memory it is enough that we apprehend a thing again, after the same manner as we received it: but to Remembrance it is requisite, that the thing be first forgotten, and then that we hold another thing fast in Memory, whereby we are brought again to the knowledg of what we had forgotten.

Nor does it seem necessary to hold any more internal Senses. Some indeed do add the Æstimative, to discourse from that which is known to that which is unknown in particulars, or to perceive those things which the Senses could not perceive: for examples sake, when the Sheep sees only the color, bigness, and shape of the Wolf with its eyes, and yet does not for these things fly the Wolf, they conceive it necessary to add an Æstimative Faculty, whereby the Sheep discerns the enmity of the Wolf against it self, which fals not under cognizance of the external Senses.

But this Opinion seems not agreeable to truth: For the Faculty of Reasoning and Discoursing is only in Man alone; and for the apprehension of al sensible things, the Fancie alone is sufficient: nor must we hold a peculiar faculty which they cal *Æstimativa*, because of the enmity, pleasure, hate, or pain which Animals perceive from some things. For these are nothing in the sensible object it self, but passions and affections following upon the perception of a thing, and proceeding from a certain proper natural Instinct which is granted to living Creatures to stir up the appetite, either to seek or shun the object. For in the perception of al sensible things, these three things do follow one another in order: First the

perception of a sensible object under the proper notion of an object: Secondly, pain or pleasure arising from the said perception: Thirdly, a stirring up of the Appetite, which either seeks the object as pleasing, or shuns the same as displeasing. The two former do pertain to the same faculty, viz. The sense or Phantasie, yet with some diversity. For the Apprehension of the object under its proper notion, is the work of the Sense as Sense, and the Fancy as Fancy; and al Living Creatures do perceive the object under the notion of an object after the same manner, both with the external Senses and the Phantasie: as al Creatures discern a white color as white, none as black. But the Apprehension of the object as pleasing or displeasing, is not of the Sense as Sense, nor of the Fancy, nor do the same things seem pleasing or displeasing to al Living Creatures: but this belongs to the Senses as they are limited and determined by the proper form of every Creature; which because it is for the most part unknown to us, is by some called natural Instinct. Hence the sight of a Wolf is painful to the Sheep, which yet it is not to the Lyon, but rather a delight if the Lyon be hungry.

This Question is by *Zabarella* thus explained. But it may to the same purpose, yet peradventure more cleerly, be thus briefly resolved. In al living Creatures there is not only the Vegetative and sensitive Soul; but also as was said before a certain peculiar specifick form, whereby every Living Creature differs from others of another kind, as for Instance whereby a Lyon differs from a Man, an Horse, an Ox, &c. This in Man-kind is the Rational Soul; and in Bruits also, it is a peculiar soul, which though it be not a rational soul, yet it answers to the Rational Soul in Men, and is in some more noble, in others less noble; and to this al those more noble operations, which cannot be referred to the Senses, and are different in several Creatures, are to be ascribed.

And therefore their Doctrine is not true (among whom is *Piccolhomineus, de sensibus internis, ch.* 11.) who hold that it is one of the Offices of the Fancy, to ad submotions, and to judg the objects to be agreeable or disagreeable to the Creature; also that it is the principle of sundry admirable works, which irrational Creatures perform, as the Swallows making her nest, the Spiders weaving her web, the Bees making her Honey-comb, &c. For as in Man, to reason is not a work of the Fancy; so in Bruits it is not the work of Fancy to act such things as are proper to their kind, but of a superior faculty, whereby every Bruit is distinguished from other Bruits.

whether brut beasts are ratioval?

Hence that Question of some may easily be decided, Whether Bruits are Rational or no? That they are not Rational is certain, because they are not Men. Mean while as a man not by his Fantasie, but by Reason is differenced from other Living Creatures: so the soul and specifick form of every Bruit hath a proper faculty above the Fancy, whereby it differs from other Bruits. And hence there is so much variety in the actions and works of Bruits, and some are more ingenious and crafty than other some; the Fox than the Hog, Ox, or Ass; the Bee than the Fly: Of which matter he that would rightly judg, let him consider what is written of the Works of Elephants, Dogs, Silk-worms, Bees, &c. and what dayly accurs in Nature.

Chap. 8. *Of the Desiring and Moving Faculty.*

HAving treated of the knowing Faculty of the Sensible Soul: we are now to speak of the Appetite. And although there are sundry Appetites, and as *Scaliger* in *Lib.* 1. *de Plantis*, writes, the Fire is said to have an Appetite to mount aloft, the Iron to joyn it self to the Load-stone, a Plant to augment its moisture, an Horse to Venery, a Man to blessedness; yet here we treat only of that kind of Appetite which they commonly cal Sensitive; which is a power of the Soul, whereby a Living Creature hath an inclination towards something perceived by the sense. Its object is some good thing apprehended by Sense, whether it be really good, or only appear so. For the Appetite tends to an end; and every end hath in it the notion of goodness. But although the Appetite is said to seek good, and fly from evil: yet evil also belongs to the Appetite under the notion of good; for to fly evil seems to the Appetite a good thing. From the Appetite as its acts proceed the Passions and Affections so called.

what the Appetite is

The Motion of living Creatures.

The Appetite of Living Creatures is followed by their voluntary motion; for unless the Creature had a power to attain what the Appetite desires, it were a vain thing for it to have an Appetite; but Nature doth nothing in vain, but hath granted a faculty to Animals springing

ging from the Senſitive Soul, whereby they can tranſfer either their whol Body, or ſome part thereof, from place to place.

Now to cauſe this Motion, five things are neceſſary. *Motion how cauſed.*

I. An Object, which may excite the Creature to move, and for the ſake whereof it is moved. For a Living Creature is not moved in vain: but the Appetite is ſtirred up by the Object as its end and good thing deſired.

II. There muſt needs be a directing Principle by which (being in the living Creature) the firſt motion is made. For voluntary motion is given to living Creatures, to ſeek out things profitable, and to fly things hurtful; which cannot be done, unleſs there be ſome power which may know the Object, and offer the ſame to the Appetite, and incite the ſame either to ſeek or to ſhun the ſame. And therefore this principle ought to partake of knowledg. Moreover, becauſe a living Creature is moved not only to things preſent, but abſent alſo; it ought to perceive not only things preſent, but ſuch alſo as are abſent. But theſe conditions do neither ſuit with the nutritive Soul, nor the external Senſes, nor the common Senſe: but only with the Fancy. For although the mind alſo may direct to Motion: yet it is a more remote principle of motion, nor does it move without the Fancy; whereas nevertheleſs the Fancy may move without the Mind; as we ſee in Bruits, which though deſtitute of Reaſon, yet are they incited to motion by their Fancies.

III. To come a little neerer, the Principle of Motion and that which commands the Motion is the Appetite. For becauſe the motion of Animals is made to follow after ſome things profitable and convenient, and to fly ſome things adverſe and noxious; and that to the Appetite belong the affections of Love and Hatred: of neceſſity in the next place the Locomotive or ſtirring Faculty is moved by the Appetite, ſo that the Appetite commands Motion.

IV. Beſides the Appetite, there is need of an executive power, which may produce into act that motion which is commanded by the Appetite, and perform the ſame. For ſince Local motion is a different operation from the operation of the Appetite, and the operations of the Appetite are immanent, but motion a tranſient action: another power muſt be granted, which is the immediate cauſe of Local voluntary motion in Animals.

V. Finally, An Inſtrument is requiſite by which the motion may be performed. For Experience ſhews, that thoſe who have ſome Member maimed, although the object be at hand, and the Fancy do move the Appetite, and the Appetite command motion, yet they cannot ſtir, becauſe of the unfitneſs of the Inſtrument. Now though there is ſome Controverſie among Authors, what is the Inſtrument of Motion; yet we hold that it is a Muſcle. And whereas ſome make anxious Inquiſition, which part in a Muſcle is the chief Inſtrument of motion, whether a Nerve or a Tendon; they ſeem herein to buſie themſelves more than they need. For, as *Ariſtotle* hath it, 2 *de Part. Animal. cap.* 1. The power of ſenſe is in the ſimilar parts, but the Actions are performed by parts diſſimilar.

The manner and order of the motion of a living Creature.

The voluntary motion therefore of a Living Creature is made after this manner and order. In the firſt place an external object is offered, which as an immovable mover, being received by the external Senſes and the common ſenſe, is communicated to the Phantaſie, and is thereby known what it is. Afterward more attently and punctually it is known whether it be convenient and acceptable, or hurtful and unpleaſing. This knowledg is followed by Love or Hate, or an Appetite to lay hold on a thing grateful and delectable, and to avoid a thing hurtful. This Appetite in Bruits is preſently followed by motion.

But in Man, before motion be made, ſome things do yet intervene. For the Appetite and theſe motions of the internal Senſes are offered to the Mind, that they may be thereby approved or diſapproved. If they be approved, and the mind underſtands that the Appetite of the Senſes is right, preſently motion follows: but if it be rejected as falſe, a contention and fight ariſes betwixt the ſenſitive appetite and the rational, til the one vanquiſhes the other; and that which overcomes is the principle of the motion, and commands the motive faculty to move. The motive faculty being implanted in al the Muſcles of the whol Body, does contract ſuch Muſcles as are needful: the Muſcles being contracted draw the Tendons to them, the Tendons being drawn draw the Bones: finally, the Bones being moved, the Member or whol Body is tranſferred from place to place.

Chap. 9. *Of Sleep, Waking, and Dreams.*

SLeep and Waking are Affections of the Senses hitherto explained. For we perceive a Man is awake, by the exercise of his external senses; and that he is asleep by their cessation from operation. And therefore sleep seems to be a privation of waking: and sleep and waking belong to the same faculty, *viz.* the sensitive: and sleep and waking are affections of the sense, agreeing to all Animals and to them alone. And therefore things destitute of a sensitive Soul neither sleep nor wake, as Plants. Again no Living Creature doth alwaies sleep, nor alwaies wake. For because al things must necessarily be weakned in their Operations, and the Spirits are consumed by the operations of the Senses; Sleep is also necessary to repair the strength and restore the Spirits. And though this be not so manifest in the more imperfect Animals, which are not furnished with all their Senses; yet manifest experience convinces that the more perfect Animals do sleep. Of which see *Aristotle* in his 4. *de Hist. Animal, cap.* 10. *Pliny* in *Lib.* 10. *Nat. Hist. cap.* 75.

the Cause of Sleep. Now Sleep is not every cessation of the Senses, or impotency in the exercise of the Senses: for even in swouning fits also, and other Diseases, the operations of the Senses cease: but when there is an inability to operate in the first Organ of Sense. Sleep therefore is a natural cessation of the common sense and the other senses, caused for the good of living Creatures, or as *Aristotle* saies in his *B. De Somn. & Vigil. cap.* 3. *It is the Cessation of the first original of sense, as being unable to act*, of which definition see *Scaliger* in *Exercit.* 289. Now the common sense is chiefly affected in sleep; and it resting the other external senses rest also. But the other internal senses do not alwaies necessarily rest in sleep: but if they do, it is because the external rest. For if the Fancy doth sometimes not operate in sleep, that doth not therefore happen because sleep is an affection or adjunct thereof, but because there is nothing brought unto it from the external senses to busie the same.

Now what the Cause is which thus binds as it were the external senses, is worth our Enquiry. The cause whereof is nothing, but that the animal spirits do not flow from the Brain into the Organs of the Senses. But what should hinder the Influx of the spirits is somwhat obscure. *Aristotle de Somno & Vigil. cap.* 3. held that this was caused by obstruction of the passage of the common sense, through which the animal spirits as a common Instrument of the Soul are sent into the Organs of all the senses. Now the obstruction he saies is caused by vapors, chiefly such as are carried out of the Stomack into the Brain. For they when the living Creature rests, whereby the Brain becomes somwhat colder, are condensed, and become more thick and heavy, and so begin to descend again, and stop the passages of the Nerves, so that the animal spirit cannot be carried into the Organs of the Senses, of which thing there are many tokens: for after meat, especially if we have eaten liberally, we become sleepy, and Persons that are drunk sleep exceedingly: contrariwise, such as have fasted long cannot sleep a nights, and most sleepy medicaments do send many vapors into the Head, or cool the Brain, that the vapors may be therein somwhat thickned, and so may stop the passages. Others contrariwise, conceive the sleep is not caused by vapors, nor by such things as stop the passages of the Nerves, but because the soul draws back the spirits to it self, lest by continual operation the animal faculties should be destroyed. Hence not only after Meat sleep comes; but Musick, Weariness, Darkness, and Quiet cause sleep.

But both these Opinions ought (I conceive) to be joyned together, and thus Sleep is bred. The living Creature being composed to rest, the Soul finding a kind of languishing feebleness, by reason of the operations of the senses all day long, dissipation of the spirits, and absence of the quickening heat of the Sun, endeavors a restauration and recreation of the strength and spirits to the preservation of the living Creature in Health. And because the animal spirits have their original from the Vital, that the Vital may first be restored and repaired, the Heart draws to it self some Heat, which is scattered into the other parts. Hence the remote members, and especially the Brain, becomes a little colder, to which the coldness of the nights Air, and the Ceasing of the bodies motion, which causes heat, do lend an helping hand: but the Heat about the Heart and parts thereabouts is encreased. The Heat there encreased raises out of the Aliment certain sweet vapors, which being carried to the Brain, by the coldness thereof are a little thickned, and begin again to descend; and slipping into the roots of the Nerves they fil and stop their passages, and are the cause, both that the vital spirits and Heat cannot ascend out of the lower parts into the Brain, and that the animal spirits

cannot

cannot be distributed into the Organs of the Senses: for want of spirits all the members do hang loose, and al the operations of the external Senses do cease.

the End of Sleep.

The End therefore of Sleep is to restore the strength of living Creatures. For because much spirit is consumed by motion, and the operation of the external senses, that the Creature may not be endamaged in point of health, they must of necessity be restored. *Scaliger* in *Exercitat.* 289. adds another End, in these words: *Sleep was made by God, not only (as is wel said) to refresh and repair the Body, but for the Liberty of the Mind. For because if you regard the offices of life, when we sleep we live but the life of Plants; it was his pleasure that then we should truly live: For the Servant at that time is free, yea and becomes a Master sometimes in his Dreams. The Minds of evil men are punished in Dreams, those of good and wise men become divine, by the searching out of truth and performance of laudible offices. For being freed not from the Body, but from its service, they do their own work: for they move themselves, and also advance themselves to the Pattern of their End which they shal in time see face to face.*

Watching.

To Sleep, *Watching* is opposed, which is nothing but the Activity or Freedom of the Senses. Now a living Creature is wakened from sleep two manner of waies, either of its own accord, or being disturbed and troubled by some external Cause. The first manner is most natural, and comes to pass when the Heat which had hid it self within, for the digestion of the aliments, and reparation of the spirits (concoction being finished, and the spirits repaired) doth again break forth into the outward parts, and discusses those vapors which were an obstacle to the Spirits, that the Spirits may freely pass into the Organs of the senses. Now although sometimes the living Creature is awaked of it self, before concoction be finished (if sharp vapors arising from bad humors be carried into the Brain; or through some other Causes) yet this manner aforesaid is most common and natural.

Now the wakening of a man out of sleep by external things, (as if a man be rouzed by crying aloud and pulling) is caused by perception of external sensible objects. For although in sleep there is a defect of spirits in the Instruments of the senses: yet the Organs are not quite void of animal spirits, but there are some yet remaining in them, which are sufficient to perceive vehement sensible objects. Therefore the sensitive soul in sleep being stirred up and provoked by a vehement external object does begin to exercise its senses, and at first it obscurely perceives the object, but afterward that it may more clearly discern the same, it gives out a greater quantity of spirits; which seeking way to the Organ of that sense which is affected, they break through the passage of the common sense; and so way is opened to the Organs of al the Senses, and consequently the sleep ceases. Hence they who in sleep have the passages of their senses obstructed by many thick vapors, which is usual in such as are drunk; they are hardly awakened, nor can their spirits easily find their passage: but those who abound not with thick vapors are easily awakened. For the same cause the first sleep is more sound and deep; because the vapors in the first concoction are more plentiful and thick, which afterward are by little and little consumed and attenuated.

what a Dream is.

In sleepy Dreams do happen, which are no passion of the external senses. For in such as sleep (who only Dream) all the external senses are bound and tied up. Nor is a Dream a passion of the rational Soul: for Dogs and other Creatures Dream as wel as Man-kind. But a Dream is an adjunct of the internal senses, and especially of the Fancy: and it is defined to be a Phantasm or Apparition happening to such as sleep.

And because in such as Dream the Fancy is busied, and some apparition appears thereto; and we Dream not only of things which we have done in the day time, but also of things a great way off, and which we have neither seen nor heard, nor perceived by any of our senses, yea and of things never yet done, but which are hereafter to come to pass: The Question is how the Images of things absent, never perceived by our senses, and which are not yet come to pass, can be offered to our Fancy. The Epicureans held (as appears out of *Lucretius*, *Lib.* 4.) *That certain thin Images do come from the outsides of visible objects, which are as it were their Skins and Barks, having the representation of the things from whence they came.* And these they thought did insinuate themselves into Persons asleep, and foreshew things to come. But this Opinion hath been long ago rejected.

The conceit of *Cœlius Rhodiginus* is not much better, who in the 27. *Book of his ancient readings*, *Chap.* 11. denies that there are any such Images flying up and down in the Air, as the Epicureans imagined: yet grants that there are certain motions which exercise and work upon us in stead of Images, and that they do proceed from the Beginnings of certain things afterwards to be said or done, the Air being first changed, which being afterwards through

the

the Noſtrils and Ears tranſmitted to the Heart, they cauſe us in Dreams to foreſee the events of future things. And that theſe motions cannot at any other time make themſelves ſenſible ſave in the night. But what motions can there be of things which are not? or how can things abſent fifty or a hundred miles al along affect the Air? or why ſhould not theſe motions affect any perſons that ſleep, but only ſuch as are concerned to know the thing revealed?

We refer all ſuch Dreams which are of things which we never before perceived with our Senſe, or ariſe from cauſes which are not in our bodies, unto a more Divine power. Thus therefore we conceive Dreams are to be divided.

The Differences of Dreams.

Dreams are ſome Natural, others Supernatural or Divine. The Natural are ſuch as proceed from Natural cauſes. And theſe again are by ſome divided into Animal and Natural peculiarly ſo called. Thoſe are called Animal which are converſant about ſuch things as have been preſented to us while we were awake. For certain ſpecies or Images of ſenſible things are imprinted upon the internal Senſes, which remain even then when the Senſes work not, and when ſenſible objects are abſent, and raiſe dreams. Theſe though they do not alwaies appear to perſons awake, being buſied about other objects: yet in perſons aſleep, the Senſes ceaſing to operate, they again ariſe, and preſent themſelves to the Fancy. Theſe Dreams do not alwaies preſent things to us juſt as they were acted: for nothing can be imagined ſo fooliſh, abſurd, and monſtrous, which is not preſented unto us ſometimes in Dreams. For the Soul being not wrought upon by external Objects, revolves the Images or things formerly preſented, and joyns this with that as each offers it ſelf, and of many and divers things compounds one; alſo it wonderfully confounds the order and circumſtances of things. And to this the plenty of bad vapors is a furtherance. For as bad vapors and humors in perſons awake, as in ſuch as are melancholy and mad, by diſturbing the Brain are a cauſe of abſurd cogitations; ſo they do the ſame in perſons aſleep; ſo that it is rightly ſaid, Dreams are the Ravings of perſons aſleep, and Ravings are the Dreams of ſuch as are awake. Hence melancholick perſons, and ſuch as have over eaten, have abſurd and terrible Dreams. And for the ſame cauſe, ſuch as are drunk, and thoſe that firſt compoſe themſelves to ſleep, have for the moſt part no Dreams; becauſe there is in them ſo great ſtore of vapors that their Brain is filled, and al the images overwhelmed: But towards day, and after the Meat is digeſted, the Dreams are more cleer, becauſe the vapors ariſing from the Meat are attenuated and for the moſt part diſcuſſed.

Animal Dreams.

Natural Dreams.

But Natural Dreams are ſuch as ariſe from ſome hidden cauſe in the Body, as the humors, temperaments, &c. For if ſuch a cauſe be vehement, it may even in ſleep alſo affect ſome external ſenſe, and preſent an image of it ſelf to the Fancy; yet it ſeldom does it diſtinctly, but by the appearance of ſome other thing like to it, or joyned with the appearance of a like thing. So, as *Galen* relates *de Præſag. ex Inſomniis*, when a certain man dreamed that one of his Thighs was turned into a ſtone, a while after unexpectedly he was taken with a palſie in the ſame Thigh.

Supernatural Dreams.

Divine Dreams.

But to Supernatural Dreams we refer al thoſe which are ſent into us by higher and ſupernatural cauſes; whether it be by God, good Angels, or Devils. Such as are infuſed by God and good Angels, are termed Divine, of which ſome examples are extant in the holy Scriptures. For the moſt good and great God is wont to preſent to men in Dreams, either new Images of things, or ſo to order and joyn ſuch as were in them before, that they may become warnings of things to come. Alſo the Angels are wont to excite and aptly to diſpoſe ſuch Images, Spirits, or Humors as are in the Body, as that they may admoniſh a man of ſome neceſſary and profitable thing. But Diabolical Dreams are cauſed after the ſame manner as the Angelical, but to a different end: For the Devil ſtudies to do men miſchief, and endeavors even by Dreams to poſſeſs them with vain Superſtitions; which the Oracles ſuggeſted in Dreams do witneſs; ſome examples whereof are related by *Tertullian* in his Book *de Anima*. *Cœlius Rhodigin. antiq. Lect. lib.* 27. *cap.* 14. or by ungodly and laſcivious Dreams he endeavors to allure men to luſts and unlawful pleaſures.

Diabolical Dreams.

From the Premiſes it is apparent how even abſent and future things may be preſented to us in a Dream. The Platoniſts conceive many Dreams may be cauſed by the Geniuſes and Spirits which they conceived did attend upon every man, and admoniſh them of many things; and the Divines refer them more rightly to Angels, which many think every man hath to attend him. But this ſeems fit to be added to what hath been ſaid out of *Tertullian*, who in his Book *de Anima* thus writes; the liberality of Divine Dreams is alſo wont to drop down upon prophane perſons, God making the Sun to ſhine upon the juſt and unjuſt. For even *Nebuchadnezzar* had a Divine Dream. And as Gods goodneſs vouchſafes it ſelf to Heathens,

Heathens, so also the tentations of the Devil do follow even holy men, whom he abstains not to tempt by day, or to molest when they are asleep, if he cannot do it when they are waking.

Touching Divination by Dreams.

From what hath been said it is ease to collect what we are to think of Divination by Dreams. For Dreams are either Significative, which foretel somwhat; or Nonsignificative, which foreshew nothing. Again, significative Dreams are either Theorematical, which cleerly expres the Nature of the Event; or Allegorical, which expres the thing foreshewed wrapt up in figures and Allegories. To explain these latter is not in the reach of every one; but they are the best expounders of Dreams, who can best discern the similitudes and resemblances of things: whereof the Books of Interpretations of Dreams do treat.

The Dreams infused by God and good Angels do questionles foreshew somwhat to come: but al cannot expound them, only they that have it granted them by God. Most Diabolical Dreams are vain, and sent to allure men to sin; and if any of them be true (for the Devil also can sometimes conjecture things to come, knowing them by their superior Causes or Signs) he does also by them endeavor to draw men to some false Religion. But Natural Dreams, which arise from the Constitution of our Bodies, do also afford signs thereof; and Physitians are wont to observe them; and what Dreams do argue such and such Constitutions of Body, is taught at large by *Hippocrates*, *de Insomniis*, and by *Galen* in his Treatise *de præsagiis ex Insomniis*: and seeing these are most frequent, it is wel said by the Preacher, *Ecclesiastes* 5. *In the multitude of Dreams and many words there is much vanity: but fear thou God.*

Chap. 10. *Of the Differences of Living Creatures.*

HAving spoken of the Form of Bruit Beasts, we should now speak of their Bodies. But forasmuch as Man of al Animals or living things (for we trouble not our selves whether these terms do differ, of which see *Scaliger*, *Exercit.* 216.) is the most perfect; and in every kind the more imperfect are to be judged by the most perfect: Moreover, the parts of al Animals or Living Creatures are not yet known and described; but in the description of the parts of Mans Body Anatomists have been as diligent as can be imagined: Such things as should have been said of the parts of Living Creatures in general, must be fetcht from the History of the parts of Man; and such things wherein the parts of other Creatures differ from those of Man, must be taken into consideration. We shal here therefore treat rather of the differences of Animals; where also some things wil fal in our way as touching their parts. And seeing every living Creature consists of a Soul and a Body, we wil weigh and consider the chief differences which flow both from the Soul, and from the Body, and from the whol Creature, consisting and made up of both.

The differences of Living Creatures in respect of the Vegetative faculty.

And first as to the Vegetative Faculty, three things are therein considerable: Nutrition, Augmentation, and Generation. And as for Nutrition, there is no Bruit Beast which does not eat some kind of food or other: for some eat flesh, as the Wolf, Tigre, &c. some eat divers kind of things promiscuously, as Dogs; some Herbs and Corn, as Horses, Harts, &c. some feed on Worms, as very many Birds; and some on Fishes. And of these again, some hunt for their living, and prey upon other Creatures, as the Crocodile, the Lyon, the Wolf, &c. some lay up their Meat in Summer, as the Pismires; some seek their Prey night and day.

As to Generation, Bruit Beasts have doubtles a Faculty (which they received from the blessing of God at the Creation) of multiplying themselves by mediation of a certain Seed, whether it be properly so called, or analogically, in such things as are commonly said to be produced by equivocal Generation. For we find by experience that Insects and such like things, which are said to be produced by equivocal generation, are not generated in any, but only in some peculiar sort of matter. For a Beetle is not bred of any, but only of some determinate sort of Matter. Hence also it comes to pass that Beasts generated of a putrid substance, containing therein a fitting Seed, are not found to differ from other Creatures of the same name. For besides that they agree altogether in form and figure, they do moreover possess the same proprieties, and perform the same operations, and can beget their like.

A threefold Generation of Living Creatures.

For living Creatures are produced three manner of waies: Some by a mutual Conjunction of male and female; some out of the putrid matter of a corrupted body, but containing in it a seed fit to propagate such a Creature: and some are produced both waies, viz. both by Copulation

Copulation and by putrefaction, as Mice, Locusts, Beetles, Flies, &c.

Moreover, Bruit Creatures ingender after sundry manners; some produce live Creatures, and are therefore called *Vivipara*, as Does, Bitches, Dolphins, Vipers; some bring forth Eggs, out of which cherished with a benign gentle Heat, are hatched Chicken, Birds, Fishes: Finally, some bring forth a Worm.

What an Egg is. *Aristotle* defines an Egg, that thereout an Animal does exist, not from the whol, but from one part thereof only, the rest being turned into nourishment: and a Worm he defines by saying, that the whol grows up into an Animal. And so *Aristotle* divides an Egg into two parts; which in perfecter Creatures are manifestly different and distinct in color; but in the imperfecter sort of Creatures they are not seen distinct, but both are confounded and jumbled together into one substance.

Of which part of the Egg the Creature is made. But of what part of the Egg the Creature is made, is a controverted point. *Hippocrates*, or the Author of the Book *de Natura pueri*, saies, That it is made of the Yolk; *Aristotle* saies of the White. If we consult with experience we shal find it as *Aristotle* saies; and thus we shal find it to be: If you shal open an Egg the second, third, or fourth day after the Hen hath sat upon it, and diligently view the same; you may easily observe that the Heart is the principal Member: For it is easie to see that the rude Chick is first formed, and in it, first the Heart, which sends forth two veins; and after the generation of the yong Chick, the Membranes which are thereto subservient are evidently seen to grow together. And indeed on the eighth day, the heart is not only apparent, but together with the Veins, being of the same red color, it is manifestly seen to move and beat. On the fourth day the bodies of the Membranes being now confirmed and grown thicker, begin to be less transparent: on the seventh day by reason of their compactness, they obscure the whol Chick in a manner, or cover the same; yet the Heart is seen by its conspicuous red color, as also the Veins, and by its motion. Mean while, the Liver does not yet appear, but on the seventh day there is first seen a liquor or yellowish slimy Matter underneath the Heart, which is the beginning of the Liver growing together, and in the following daies it makes up this Body of the Liver; till which time there remains much of the Yolk, yea, when the Chickens are hatched. And in this place of the Liver for nine whol daies together, after the first formation, no blood is seen; the heart notwithstanding in the mean while being ful of blood, as also a most large Vein, drawn under the heart, the whol Bodies length. By al which it appears manifest, that the Soul sticks in the Heart as in its Root, and that the Heart is the first thing which lives, and is the Creature as it were.

But of which part of the Egg the Chick is framed, and with which part it is nourished, is not so plain: yet thus the matter seems to go. Much about the middle of the Egg longwaies, where the Yolk is joyned to the White above, the second day after the Hens sitting, there is a certain whitish beginning, more compact than the rest of the White, and as it were through a glass there is the appearance of a Chicken, the head being most conspicuous, and near the Head a red point dilating and contracting it self: The daies following, from that red point a very red Vein is drawn al along the Chickens back, every day further and further; from which afterwards Veins proceed to the skins drawn about the yolk. By which it may be conjectured, that the Chick is first made of the White; and that the aliment to be turned into blood is made of the Yolk, and carried through the Veins to the little skins stretched about the Yolk, and perfected in the Liver, which Liver hath also a similitude with the Yolk. Yet if any man shal hold, that the Yolk gives nourishment to the blood and parts nourished with blood; and the White to white parts bred of it self, and like to it self, til the Liver grow so strong as to be able to afford nourishment to al the parts, and that therefore the place of shaping is in the confines of the White and the Yolk, I shal not contend with him thereabouts.

Howbeit some Creatures there are, which engender not only often, but bring forth many yong ones at a time, as Swine, Hares, Pidgeons, &c but some bring forth few yong at a time, and seldom also. And al for the most part by mediation of the two Sexes; nor are the Sexes confounded in any kind of Creatures, so that the male should be female, or the female male; which some confidently affirm of Hares. Although it may be perhaps granted, That Hermaphrodites are more frequent in this kind of Creatures than in any others.

The difference of Creatures according to the sensitive faculty. Secondly, There is also some difference in Creatures with reference to the Sensitive Faculty: For every sense is not allowed to every Animal; howbeit the Feeling, as the first sense, is granted to al Creatures. And those that have only this sense and want al the rest, are called *Zoophita*, Plant-animals. All other Creatures have more Senses. Nor do we think fit to deny Sight to the Moles; for to what end have they Eyes if they cannot see? For

Moles.

although

although they have no need of sight, to see under the ground, yet they have it given them to avoid the light and the bright air; of which see *Scaliger* in *Exercit.* 244.

Howbeit, some Creatures excel in one sense, some in another; some in seeing, others in smelling; some in one are more excellent, some in another, both external and internal Senses.

The difference of Animals in respect of the Locomotive faculty.

Finally, there is great difference in living Creatures, with reference to their faculty Locomotive, whereby they remove from place to place: For every Creature does shift place, but some after one manner, and some after another. Some only in part, as was said of the Plant-animals, which though they are always fixed in the same place, yet they contract and dilate themselves. But others move their whol bodies, some after one manner, others after another: For some Beasts go, and that either on two feet, on four, six, or more, as Spiders; some move themselves by swimming, as Fishes, and some that live both on Land and Water; others by flying, as Birds; some by leaping, as Grashoppers; finally, some by creeping and crawling, as Worms and Serpents, who by contraction and dilatation of their bodies do move themselves from place to place.

the difference of Creatures in respect of their parts.

Moreover, in respect of their parts, there is a great variety in Animals: For as *Aristotle* hath it in 1. *de Hist. Animal. cap.* 2. *Parts of Animals are the same and divers, either in form, or sort, or exuperance, or analogie, or scituation.* And in the first place the parts by which they take their nourishment, and whereinto they bestow the same, are common to al Creatures. For the necessity of food is common to them with Plants: which Plants indeed have from the Earth, and therefore sticking in the Earth they have nourishment enough. But Animals (seeing they are more perfect than Plants) they were to have more exquisite diet than such as the Earth affords. And therefore they had not only tast given them to try their meats, but also members wherewith to receive the same, and turn it into juyce fit to nourish the body, viz. The Mouth and Stomach.

Now this Aliment received is in several Animals severally changed into Nutriment properly so called, or an humor which is the immediate aliment of the body, which when either by Nature it self (the heat in process of time devouring the same) or by violence (as in sicknesses and other cases) it comes to be consumed, the life is extinguished. Now this Humor, the next aliment of the body, is in some blood, in others a fatty and bloody moisture, like Sanies or Blood-water running from hurts of the body; as also the part wherein this aliment is contained is in some a Vein, in others a Fibre. Hence Animals are divided into such as have blood, & such as are bloodless. In the more perfect sort of animals, intended for nobler actions, and therefore needing more heat, this Humor is red and is called Blood. Yet there is in some bloodless Animals a certain red humor which is not blood, but an excrement, as in the *Purpura*. But other Animals whose bodies are more imperfect, do also need a less perfect nourishment; if moist, an white; if dry, a more obscure humor: which humors having no proper names, they are termed *Ichores*, and are blood as it were newly begun to be made and imperfect. As also in Creatures that have blood, when the blood is not wel elaborated, it puts on the nature of an Ichor as it were, as we see in Cachectical persons.

the Polypus.

the Elephant.

Also al Living Creatures have an Head, except the *Polypus*, who instead of an Head carries as it were a Hive. Limbs are wanting in some Insects; in others the fore feet are instead of fingers. The Elephant instead of hands hath his Trunk let down from his Mouth. Fishes have no necks. Most Creatures have Tails, and they are of several fashions, which Man hath not. Instead of Teeth Birds have Bils of a boney nature, wherwith they do break their meat; instead of Nostrils they have only two holes; as also two passages instead of Ears. Moles have their Eyes obscurely buried, yet are they not without Eyes. Instead of a Tongue many Creatures have a fleshy substance in their Mouths; and many with an external sharp cool spungy and hollow do both tast and draw their meat to them. All Creatures that have Blood have Skin. There is in all Creatures having blood and heads properly so called a Brain, which on the fore side is divided into two parts. The Seeing, Hearing, and Tasting Nerves, with the other parts which make up the whol Organ of Sense, are found in al perfect Animals. And the Heart, or at least somwhat answering thereto, is in al living Creatures. There is no Lungs in Fishes; instead of members of generation, Fishes and Serpents have certain holes ordained for their seed. Most of the Guts and Bowels are to be seen in perfect living Creatures; but in the imperfect they do not exactly agree with those of a Mans body, and for the most part they differ in Fishes and Serpents. Fishes instead of bones have a spine. Insects have a condition proper to themselves; for they have a cloven flesh obliquely directed, and somthing of a middle nature betwixt nerves and flesh, which is to them in-

ſtead of Bones and Spines. Proper Spirits are given to every living Creature, which the Soul doth immediately uſe to exerciſe ſenſitive actions.

Difference of Living Creatures from the place where they live.

Moreover there are other Differences of Animals from the places wherein they live, and their Actions. For firſt, ſome inhabit only one Element and live thereof; in the Air the *Manucodiata*; in the Water the *Apua*; in the Earth the Toad. But whether there are any Creatures that live in the Fire, Authors are at variance. Some hold that the Salamanders and Pyrauſtæ live in the Fire, as *Ariſtotle*, *Pliny*, *Ælian*, *Auſtin*. As to Salamanders they are ſo far from delighting in Fire, that they are found no where but in places both cold and moiſt, and they put out moſt hot burning coals, either by their coldneſs or clammineſs of ſubſtance, before they can be burnt. That the Pyrauſtæ live in the Fire *Scaliger* eagerly defends, *Exercit.* 9. 23. *and* 194. *ſect.* 4. But others hold there is no Animal which is not burnt and kil'd in the Fire; and that the Pyrauſtæ indeed are bred and foſtered in little holes about Furnaces, but never bide in the Fire, whereinto being caſt they are burnt: which is probable. Some Living Creatures live in two Elements, and find their meat in both, as Bats or Flitter-mice, which catch Gnats in the Air, and plunder the flitch of Bacon on Earth.

Whether any Creatures live in the Fire

All theſe may again be included under three kinds, Birds, Fiſhes, and Land Beaſts. The *Manucodiata* (a Bird) lives only in the Air: In the Ocean of *Braſile* there are Sea-Geeſe which live only in the Water, and never fly out, of a black Colour. In *Mare del Zur*, towards *China*, there are footleſs Birds, which never forſake the Water. The Oſtrich lives only on Land. The Hern lives on Water and Land. The Bat lives in the Air and Earth; The Swan lives, but feeds not in all three Elements.

Fiſhes that live in the Water and Land are the *Polypus* and Crabs. Thoſe that are in two are alſo in three; for they are in the Air, Water and Earth, that are in the Earth and Water; for they cannot be on the Earth, but they muſt be alſo in the Air.

Of Land Creatures which *Ariſtotle* terms *Pezа* (which word cannot eaſily be rendred in Latine) ſome live on the Land and Water, and ſeek their Food in both Elements, as Otters; ſome which are very greedy after Fiſh cannot endure to touch the Water, as Cats: ſome live only on the Earth.

Living Creatures are after another manner thus divided. By reaſon of their Food, ſome are Land Creatures, and others of the Water. Thoſe that live in the Water, do either take in the Water, or they do not. Thoſe Fiſhes take in the Water that are fenced with Gils. Thoſe which take not in the Water do draw in the Air, or they do not draw it in. Thoſe that draw in the Air and have Feet, are the Otters, Crocodiles, and ſuch like; of thoſe that have not Feet and draw in Air, is the Water-ſnake; ſuch as of this kind have Wings, are the Cormorant, Sea-gul, &c. Thoſe that draw not in the Air are the Utticа, and all Shel-fiſh. But of Land Creatures, all that have Blood and Lungs draw in Air; but Waſps, Bees, and all Inſects do not.

Again, of Land Creatures ſome fly as Birds, Bees; ſome go only on the Ground, either with Feet or ſome other way.

Such as paſs upon the Ground, are either Goers, or Creepers, or ſuch as draw their Bodies. Goers uſe Feet, amongſt which Leapers are reckoned: But the Creepers by twiſting their long Bodies, and bearing on two ſides, as four-footed Beaſts on two Legs of a ſide, do ſo move themſelves. Such as draw themſelves, are thoſe which put forth their former parts and draw their hinder parts after them and ſo win Ground.

The Difference of Creatures in reſpect of their actions.

As to their Differences in the actions of their Life and Manners, ſome Creatures live in Flocks and Companies, others live ſingle and ſolitary, and ſome live both ſolitary and in Companies. Birds that live in Companies are Pigeons, Cranes: the ſolitary are all Birds that have crooked Talons, none of which live in Companies. Among Fiſhes the Runners, the Tuny-fiſh, Whitings, Makerels. Now Creatures live ſolitary being neceſſitated thereto for getting their food. For though all kinds of living Creatures do fly thoſe of another kind and think they may live more ſafely with thoſe of their own kind, being allured by likeneſs: yet Beaſts that have Scarcity of food, and meet ſeldom with their Prey, as Birds with crooked Talons, cannot converſe with many of their own kind: For as ſome that meet with plenty of food, live in Flocks, as Pigeons: ſo to theſe (and to theſe alone) by reaſon of the ſcarcity of their food Nature hath given both Strength of Body and Fierceneſs of Mind; and the ſcarcity of their Foot compels them to Prey upon other Creatures.

Again whether they live in Flocks or Single, ſome do alwaies inhabit the ſame Country, ſome do go out of one into another, and return back again.

Again of thoſe that live in Companies ſome are Political, others are not, but mind only their own buſineſs. The Political are ſuch as obſerve a civil Policy, which requires that

publick

publick works be orderly performed by all, and that there be a Communion of the Profits acquired; and thus do the Bees, the Pismires, the Doves; but the Sparrows observe no such Order. For though they fly in Companies, yet each one by it self seeks its own livelihood, and labors not at all for the whol Society, which the Bees and the Pismires or Ants do.

Again, some Creatures are Flesh-eaters, others feed on Grass; some are Fish-eaters, others Worm-eaters, some All-eaters that will down with any thing, some have a meat peculiar to themselves, as the Bees, of which we spake before.

Moreover, some live in the open Air under the Canopy of Heaven, others live in little holes or Nests. And some have their Nests above, others under Ground; and of those that live under Ground, some make themselves holes, others shelter themselves in furrows made to their hands. Those that live above Ground some live in Walls and Rocks; others make themselves peculiar Houses and Nests. Again some keep themselves in their Nests all day, and at night come out to seek their food, and when it grows light they withdraw themselves into their smal Cottages: others again do what they have to do by day light, and mew themselves up when night doth come.

Again some Creatures are tame and gentle, others wild; and of the wild, some are alwaies so; but some may be and are tamed.

Living Creatures do also differ much in respect of their Voyce. For some utter a Voyce, others have no Voyce at al. Those that have a Noise or Voyce given them, have it to the End to express their Passions or their Necessities. Now these three differ, Sound, Voyce, Speech. Sound is the most common of the three: for every sound is not a Voyce, but only that souud which is made in Creatures, by help of the Lungs, Chest, Wesand, and chiefly the Head thereof, which is the immediate Instrument of the Voyce. Now some Voyces are expressed by Letters, and articulately distinct, other some cannot be expressed by Letters. The latter is simply called a Voyce, the former a Speech, which is proper to Man alone: for although brute Beasts aud irrational Creatures, can by Lowing, Squeaking, Barking, Neighing, Crowing or any other way express their Cheerfulness, Fear, Pain, Desire: yet Man alone is able to express all he feels in his mind, with a Voyce made up of Letters articulately distinct, and can communicate the same to others whom he hath been born to live with.

The Difference of Creatures in respect of Voyce. *Sound,* *Voyce,* *Speech,* *how they differ.*

Howbeit, though there are many differences of Animals, they may be reduced to certain kinds, as is apparent from what hath been said. Some are imperfect, others perfect: and the perfect are Land Creatures, Fishes, and Fowls. And if we were to speak of them all, we should pass from the Imperfect to the Perfect, til we came to Man, the Perfection of all Living Creatures.

Animals some perfect, others imperfect.

Among Living Creatures *Zoophyta* or Plant-animals hold the first place, because they are of a middle nature betwixt Plants and Animals, for in the shape and figure of their Body they come near to Plants, but in their sense of feeling, and a certain motion, they agree with Animals. For they have the sense of feeling, and being touched do forcibly contract themselves. And though they cannot pass from place to place: yet are they endowed with a power of contracting and dilating themselves.

Plant-Animals.

Of these some stick alwaies in the Earth like Plants, as a Tree which grows in the Country of *Pudifeta*, and seems to discern when things approach thereto. For when a Man, or other Creature draws neer, it shrinks in its Boughs; and when they go away, it spreads them forth again; and therefore the Inhabitants cal it the Bashful Tree. And *Apollodorus* the Scholar of *Democritus* writes of an Herb of like nature, which he therefore cals *Æschinomene*; because if you put your hand to it, it would avoid the same by shrinking in its Leaves, as *Scaliger Exercit.* 181. *sect.* 28. does write.

The bashful Tree. *The sensitive Herb.*

Also some cleave perpetually to the Stones or Sands; as the *Pulmo Marinus*, the Sea-Nettle, the Spunges, the *Holothuria* or prickly Fish. And some stick so long to the roots and fibres of Trees, til they attain their just growth, as the *Mytuli* or *Limpins*, which are said to grow on the Stalks of Sea-weed, and to stick exceeding fast to them at first; and having attained their ful growth and just bigness they fall from their branches: but they are not generated as other Shel-fish are of themselves.

Mytuli or *Limpins.*

Next after these, and the most imperfect, are Creeping things which grow upon live Animals, either without, as Crab-lice, Lice, Fleas, Ticks which trouble Dogs; but they say that they are not bred upon them, but they catch them as they hunt in the Woods; of which see *Scaliger, Exercit.* 195. *sect.* 7. or within, and not only in their Guts, but in other parts also, for Physitians have observed that there is scarce a part in the whol Body wherin Worms do not breed.

A Tick.

Hereto belong those Insects and smal Animals which are bred out of the Carkasses of other Creatures and out of Plants; as Wormes, Wasps, Gurgulions, Flies, Hornets, Cods-Worms, Wood-lice, Moths, Glow-Worms, Wig-lice, Horl-Flies, Grass-Worms. of kin to which are Spiders, *Phalangia*, *Tarantulæ*, Scorpions, and such like.

Bees and Silkworms Now among these kind of Creatures the most noble is the Bee and the Silk-worm; the former making most sweet and useful Honey; the latter spinning Silk wherewith the great ones pride themselves.

Then follow those kind of Locusts which *John* the Baptist fed upon: Nor is there any need that we should interpret the word *Acrides* so as to signifie the tops of Trees, or any Shrub, or river Crabs; seeing we are informed likewise by ancient Authors that some Nations did feed upon Locusts, as *Strabo in Lib. 16. in Descript. Arabiæ*; who also describes the manner how they caught them: and *Pliny in Lib. 11. Cap. 29.* who saies the Persians delight in them: and in *Lib. 6. Cap. 30.* that some People of *Æthiopia* have no other Meat but Locusts, which he saies they salt and dry in the Smoak to that end: and among late writers *Clenardus in his Epistles* writes, that at *Fez* and *Morocco* whol Cartloads of Locusts are dayly set to sale.

Next to these come sundry sorts of Serpents, Frogs, Toads, Salamanders, Locusts: To which are next in name and shape certain Sea-Insects, Flies, *Scolopendra*, Caterpillars, Sea-Stars, and such like.

Shel-Fish After them march the Shel-fish of two kinds, for some have their shels open but twined strangely about, such as the Purple, and the Periwinkle, and an innumerable sort of Shel-fish, whose shels are shaped like Turbants or Steeples; others shut their shels like two folding doors, that they cannot be opened without great force, such are Oysters and others of that kind, as Muscles, Cockles &c. of kin to which are Crabs, Lobstars, Cray-fish, the Sea-Locust and such like.

Purple. *Oysters.* *Lobstars.*

Fish. Next come the other kinds of Fishes smooth and without scales; then the scaly, the Prickly, the Sea, the River, the Lake-fish. Of Fishes (besides others) read *Scaliger, Exercit.* 218. and *Exercitat.* 223. 226.

Creatures which live in the Water and on the Land. After these come your *Amphibia*, Creatures which live partly on Land and partly on the Water, as the Tortoise, the water Salamander, the *Scincus*, the Crocodile, the *Cordylus*, The *Hippopotamus* or River-Horse, the Castor or Bever, the River-Crab, the Water-Mouse and Rat. Amongst which there is none that is partly made like a Fish and partly like a four-footed beast save the Bever.

Birds. After Fishes Birds must be explained. Now every Animal that flies is not a Bird, but only that which hath blood in it, and is furnished with a Bil and Feathers. Hence Flies, Beetles, Bees, Hornets, and such like are no Birds; as neither the Bat or Flitter-Mouse, which is of a middle nature betwixt Birds and Mice, and may be termed the flying Mouse.

The Swallow. Now there are sundry differences of Birds, which *Scaliger* hath collected in *Exercit.* 227. In the first place come Swallows, which fly most swiftly of all others; of which also there is some difference. These beeing commonly not fit to be eaten, neither can they themselves in the winter find their own meat, *viz.* Flies and other Creatures that glide about in the Air: after the end of Summer when flies are gone, they fly from these parts of the world, *Germany*, *France*, *England &c.* unto the shores of the Baltick Sea, and under huge high Rocks that hang over the Sea, they hang mutually embracing one another until the Spring return, and then when the Bird-Winds blow they return each to its own Country.

After the Swallows come the Sparrows, the Mag-pies, Chaffinch, Titmouse, and the singing Birds, as the Nightingale, the Lark, Goldfinch, the Liner, the Thrush, the Gnat-snapper, the Red-breast, the Bulfinch; also the prating Birds as Parrots, Black-Birds, Mag-pies, Starlings, Jack-daws, Jays or Gays.

After these come Pigeons, both tame and wild, as the Wood-Pigeon, the Stock-Dove, the Turtle-Dove and others.

And then the kinds of Cocks and Hens, and Birds of kin to them, as the Pheasant, the Partridg, the Woodcock, the Quail, the Ostrich, the Peacock.

Then follow Water-fowl, both the flat-footed, as the Swan, and several sorts of Geese and Ducks, The Bittern, the Water-Crow, the Cormorant, the Sea-mew, with the flat foot; and the cloven-footed, as the Hern, the Kings-fisher, and the rest.

Then come the ravenous Birds, the Choughs, the Daws, the Crows, the kinds of Vultures and Hawks, the Kite, the Buzzard, the Owl; and finally the Eagle, the Queen of Birds. Concerning Birds see *Scaliger* in his 227. *Exercitat.* and those that follow.

The Ægle.

The

the Bat.

The Bat or Flitter-mouse is of a middle nature betwixt birds and beasts, being a winged Mouse: which is of a wonderful greatness in some places: For *Scaliger* writes in *Exercit.* 236. *Sect.* 3. That in *Catigan* an Island of *Mare del Zur* there are Bats as big as Eagles, which the Natives eat, and they tast like Hens. And that in Caves of *Mount Atlas* there are Bats as big as our Pidgeons.

The Basilisk or Cockatrice.

And here we must not omit to speak of the Basilisk or Cockatrice. Now that there is such a Serpent called a Basilisk, is apparent from the holy Scriptures, *Proverbs* 23. ver. 32. *Esay* 11. ver. 8. and 14. verse 29. and 15. verse 5. *Jerem.* 8. verse 7. As also from *Pliny*, *Lib.* 8. *cap.* 7. and *Lib.* 29. *cap.* 4. Solinus *chap.* 30. Lucan *Book* 9. Dioscorides *Lib.* 6. *cap. ult.* Galen *de Theriaca ad Pisonem.* Aetius *Tetrab.* 4. *Serm.* 1. *cap.* 33. although Authors do not accord in their Descriptions thereof.

Whether there be such a creature as a Basilisk or Cockatrice.

But whether there be such a Basilisk as is hatched of the Egg of an old Cock is doubtful: Many count it for a fable: But it is commonly reported that there was once such an one at *Vienna* in *Austria*, and that the Picture thereof is extant on the wall of a certain house; as also at *Basil* and *Zwiccavia*, as *George Agricola* relates in his Book *de Animalib. subterraneis.* But there is a remarkable story which *Joh. Pincier* in *Lib.* 5. *Ænigmat. Ænigm.* 23. relates from the report of Dr. *Mosanus* chief Physitian at *Cassels*: which because few (peradventure) have read that Book, I shal here transcribe word for word.

A memorable story of a Basilisk or cockatrice.

At *Warsovia* in *Poland* it fel out in the Year, 1587. That the Son of a certain Sword-Cutler, and the Daughter of a neighboring Citizen, being both of them five years old apiece, with others their equals in years, not enduring to be out of action, after the manner of children they would needs pass the time in sports, and seek hiding holes where their play-fellows should not find them out. There was not far from the place where they played, a Cellar left detolate by reason the House had been burnt which stood over it thirty years before; into which by help of the half-rotten stairs one might make a shift to creep down. Into the said Cellar the two foresaid children going down, they fel down on the lower stairs and died. When Supper-time was at hand, the two Mothers each enquiring for her child could hear no tidings thereof: And therefore the Wife of the Sword-Cutler sent her Maid out, who having long sought them, at last spied them upon the stairs of the Cellar as aforesaid, and presently she cried out, See where they lie. But neither of the children stirring at al, she began to suspect they were fallen asleep, and with a loud voyce called by name, sometimes the Boy, and sometimes the Girl; to see if by this means she might waken them. But when she saw (though she cried til she were hoarse) it was to no purpose, she also went down into the Cellar, thinking to awaken them by jogging and pulling: But see what follows, presently also she fals down by the children and dies. Her Mistris saw the Maid when she went down into the Cellar, and perceiving that she staid over long, al amazed she ran unto the Cellar, and sees the Maid lie on the ground with the children: Therefore she also fals to cal aloud sometimes upon the Maid, then upon the children. And when she had done thus also in vain, and none of the three did either answer or stir, she concluded they were dead. Presently a rumor flies about the Town, and the Citizens come running, but know not what to do til the Magistrates and Council of the City being made acquainted therewith, did command that their bodies should be drawn out with long hooks, such as they use to pul down houses in the time of fires. They being drawn out were found swollen like Drums, their lips and tongues were swollen, their color was brown, their eyes stuck out of their eye-holes as big as half Eggs. There came to behold this sad Spectacle the Palatine N. and an ancient man the Kings chief Physitian, named *Benedictus*. He conjectured that some most venemous Serpent did lurk in that desolate Cellar, by whose deadly breath the air inclosed therein was infected, and that the weak nature of man could not bear the same; and that therefore most like it was that the children and maiden were thereby killed. Also that it might be that a Basilisk or Cockatrice might there lie hid, which Naturalists say is bred of a Cocks Egg hatched by a Toad, whose venom is so powerful that whoever looks upon his eyes dies forthwith. Being demanded how the certainty might be known, he made answer, That somebody must be sent into the Cellar covered round with looking Glasses, the right sides of the Glasses being outwards: For the Basilisk if he saw but his own picture or image would presently die. There were at the same time two Malefactors which three daies after were to be executed, the one being a Polander, the other a Silesian called *Johannes Faurerus*. To them it was proffered, That he that would go down into the Cellar and hunt out the Serpent should escape his allotted punishment. *John* presently accepted the condition: And therefore he was covered al his body over with Leather, and Glasses were tied before his eyes, which he could wel see through; in one hand he had an iron Rake, in the other a lighted

ted Link; finally, to al parts of his body before and behind Looking-glasses were fastened. Thus furnished he entred into the Cellar, more than two thousand people looking on. After he had for above an hour searched al the holes and corners of the Cellar, and could find no Serpent, he called upon them to throw him down another link into the Cellar: for there was another Cellar close by, but the way was so stopt up with rubbish that he could not get in; but he would now see to clear the way, and search there also. And as he was doing that, he chanced to turn his eyes to the left side, and unawares espied the long lookt for Beast in the shape of an Hen, lying dead in a certain hole of the wall: which when he had declared by a shout to them that were without, the Kings Doctor bad him with his Rake to bring it out into the light, which he presently did before al the people. The Doctor presently judged that it was a Basilisk or Cockatrice. It was as big as an ordinary Hen, its head was like that of a Turky-cock, his Comb resembling a Crown was sprinkled partly with yellow, and partly with blue spots, and his Chotters hanging under his Throat were of the same color. His Back was starred with many eminent spots resembling Toads eyes, the colors of virulent Beasts being every where sprinkled between, but chiefly yellow: The same colors also were on the outside of his Wings: Under his Wings he was al yellow, as also under his belly, where nevertheless blue and green and other wonderful colors were intermingled. He had long Legs like the Legs of a Cock, and yellow as a Quince-Apple; before and behind these two Legs there grew out other two Legs like the Legs of a Toad in shortness and shape. His Tail bowed and turned upwards, and was ful of such spots on the top as we said were on his back; lower it was yellow, and in the lowest part like a Toad in color. More may be seen concerning the Basilisk, in the foresaid Book of *Pincierus*, and the place fore-alleadged.

Lastly, There are four-footed Beasts, which come neerest to a Man both in the parts of their bodies, and the faculties of their souls. And among these are such as chew the Cud, that is to say, the meat which they have eaten, and is slipt into one Cavity of their stomach, they fetch it up again through their throat and chew it over again, and so transmit it into the other cavity of their stomach, better ground and prepared for further digestion: For what Nature hath denied them in the want of upper Teeth, that she makes amends for by this double chewing.

Moreover, all these Creatures have coverings given them instead of cloaths; for some have hairs, some more, some fewer; others have bristles, others wooll, and some furr. Again, some have solid, others cloven hoofs.

The lowest and most imperfect kind of these Creatures are Moles, Mice, Marmots, which *Scaliger* describes *Exercit.* 203. The more perfect are the sorts of Weezels, Hedg-hogs, Cats, Dogs (of which see *Lipsius* in his Centuries of Epistles, *Cent.* 1. *ad Belgas Epist.* 44.) Wolves, Sheep, Goats, Rams, Hares, Foxes, Asses, Hogs, Oxen, Apes, Harts, Bears, Elephants (of which see *Scaliger*, *Exercit*, 204. And *Lipsius* in *Epist. miscell. Ep.* 50.) Horses, Elks, Cammels, Leopards, Rhinocerots, Unicorns, and others; finally, the King as it were of al bruit Beasts, the Lyon.

whether there be such a beast as the Unicorn?

Only I must speak somwhat of the Unicorn, of which sundry men are of several minds. *Ambrose Parey* in the 20. *B.* of his *Chyrurgery*, *cap.* 39. where he disputes largely of this matter, after he hath brought the Narrations of some Authors touching this Beast, and observes that they agree not one with another, he concludes at last, That the word *Unicorn* is not the name of a real Creature in the world existing, but only a Fiction fained at the pleasure of Painters and Writers of Natural History, for the delight of the Readers and beholders.

But in very deed this is an absurd Opinion of his; it is also a rash thing to deny that which so many learned men affirm; and also the holy Scripture it self, *Job* 39. verse 9. *Esay*, 34. verse 7. *Deuter.* chap. 33. ver. 17. *Psalm* 22. ver. 22. and *Psalm* 29. ver. 6. *Numb.* 23. ver. 24.

there are five kinds of unicorns.

This rather is apparent from those manifold differing Narrations and Descriptions, That there is not only one Creature that bears a single Horn, but divers: For in the places cited, the Unicorn is made to be a Beast swift of foot, fit to be hunted; which is not true of the Rhinoceror, which is a thick beast with short Legs. Moreover, the Horn of a Rhinocerote is much smaller in compass than that which goes about for the Unicorns Horn. Also *Cæsar*, *Lib.* 6. *de Bello Gallico*, makes mention of an Ox in the Hercynian Forrest, out of the middle of whose forehead betwixt his Ears there grows one long Horn. And indeed there are Five kinds of Beasts that are thus single-horned. The Ox with one Horn in the Hercynian Forrest mentioned by *Cæsar*: And *Pliny* writes that such are found in the *Indies*

1. *the one horned Ox*

Lib. 8. *cap.* 21. Secondly, the same *Pliny* in the same place describes the Unicorn. *Ælian* *Lib.* 16. *de animalib. cap.* 20. in the third place describes a Rhinocerote that hath one black horn in his forehead as thick as the smal of a Mans Arm, of rare vertue against poyson. Fourthly, There is the Indian Ass, who also carries one horn in his forehead, of whom *Aristotle* speaks in 2. *de Hist. anim. cap.* 8. and the 3. *de part. Animal. cap.* 2. *Ælian* in *Lib.* 4. *de animal. cap.* 5. Pliny *Lib.* 11. *cap.* 37. *&* 41. Fiftly, The same *Aristotle* in the same place, and *Pliny* makes mention of a Beast with one Horn called *Oryx*. So that there is no doubt but there are Creatures that have but one Horn: only the Question is, Which of these Creatures Horns they are that are commonly given out for Unicorns Horns? For the variety of them shews, that they are not al of one Beast: and therefore it cannot be known but by the effect to be good against poyson. *Ælian* attributes that vertue to the Horn of the Indian Ass, rather than of the Monocerote, to be good against many Diseases and Poysons.

2. *The Monocerote.* 3. *The Rhinocerote.* 4. *the Indian Ass.* 5. *Oryx*

But touching al Animals or living Creatures, to reckon them up in this Compendium is impossible; and here again Nature is so vast of extent, that no mans wit sufficeth to take a muster thereof. And the Nature of this work makes us set Titles for Dishes before our Guests, which *Scaliger* taxes *Pliny* for in *Exercitat.* 107. Let the Student of Natural Philosophy consult hereof with *Aristotle* in his Book *de Historia part. & generatione Animalium*; Conradus Gesnerus *de Animalibus*; Edvardus Wottonus *de differentiis Animalium*; Rondeletius *de Piscibus*. And those that have written of some sorts, as *Andreas Libavius* in his Book *de Agno vegetabili Scithiæ*, of the Lamb that grows in *Scythia*; his two Books of Silkworms; his two Books of *Batrachiorum*, of Frogs. *Baldus Angelus Abbatius*, *de Viperæ Natura & facultatibus*: and many other Authors who have writ of Animals.

THE EIGHTH BOOK. *Of MAN.*

Chap. 1. *Of the Rational Soul.*

IT remains now that we should treat of MAN, who being the Rule and Measure of al Living Creatures, and being compared with the rest, may be said to comprehend them all, because he is furnished with al their faculties and endowments; with the consideration therefore of *Man* we shal conclude our Treatise of Natural Philosophy.

Now a Man (as other living Creatures) consists of a Body and a Soul. We shal speak of his Soul in the first place. And seeing every Soul may be considered under a twofold notion; first as a Principle and one part of a Compound, or as the Form of the Body; Secondly as the Efficient cause of al operations: We wil treat thereof also under both respects; and in the first place we wil consider how the Rational Soul stands in reference to the Body of Man: and afterwards what operations it doth work.

the Essential parts of Man.

No

Whether the Rational Soul be the informing Form of a Man.

No found Philosopher denies the Rational Soul to be the form of a man. But seeing there is a twofold Form, one which is called the informing Form, which is the Principle and one half of the Compound, and gives the thing its specifical being, and as a difference distinguishes it from al other things: another which is called the assisting Form, which does not give the specifical being to a thing, but is added to a thing already constituted in its specifical being, for the performance of some nobler operations, which of it self it cannot perform; (such a form as the Marriner is to the Ship, who gives not the Essence to the Ship, but is adjoyned thereto after it is perfect in its Essence, to cause it to sail, which it could not do of it self:) The Question is, Whether the Rational soul be the informing form of a Man, and the half of his Essence? or only an assistant form, which is added to a man after he is perfect, and hath his specifick form to cause in him some more noble operation, viz. Understanding.

Avenrois was of Opinion that the Cogitative Faculty (by him so called and distinguished from the Fancy) was the form of a Man, and by vertue thereof a Man became a particular sort of Living Creature; but that the Rational Soul was only an assistant form. But most of the Latines hold the Rational Soul to be the true form of a Man, and one of his constituting parts; which Opinion we retain as the more true: For if the Rational Soul were not the informing form of a Man, he could not rightly be called Rational; even as a Ship, though the Sailer therein do reason, cannot be called Intelligent or Rational, which were absurd. Or thus, which is the same in effect, that whereby any thing does primarily operate, is the form of the thing to which the operation is attributed. But to Man as Man Understanding is attributed: Therefore the Intelligent Soul is the form of Mans Body. Nor does that answer satisfie, when they say, That the Understanding is joyned to a Man by the Phantasms or Images of the Internal Senses: For the Phantasms are to the Understanding as colors to the Eye. As therefore neither the Color, nor the Subject of colors do see; so neither the Phantasms, nor the subject of the Phantasms do understand; but rather are themselves understood. Thus therefore we conclude: That whereby one thing differs specifically from another is the form thereof. But by the Rational Soul a Man differs from al other living Creatures; *that* therefore is the form of a Man. *Aristotle* also seems to have been of the same mind, as appears out of the 2. *de Anima, cap.* 1. *t.* 7. 8. *cap.* 2. *t.* 24. 25. 26. *cap.* 4. *t.* 36. 37. as *Zabarella* does shew at large in his chap. 7. *de Mente Humana.*

Whether there be one Rational Soul in all Men.

From the Explication of this Question another Question may easily be answered, viz. *Whether the Rational Soul be one in number in all men? or there be in every one a peculiar Soul?* Some that hold the Rational Soul to be an assistant form, do hold that it is not multiplied according to the number of Persons, but that in al Man-kind there is one only, which is the cause of Understanding in al Men. But in very deed this Opinion is many waies contrary to the truth: For every informing Form, such as we have already shewed the Rational Soul to be, is multiplied according to the multiplication of particular persons. And if there were only one Soul in al Men, al should be but one; for they should have but one Form. Moreover, the operations, or understandings, or second acts, are multiplied in Men according to the multitude of Individuals; and my Understanding is one, and thine another, a third Mans another. Therefore the Soul the first act is manifold: For the diversity of operations depends upon the diversity of Forms. Finally, in one and the same Understanding there would be contrary operations: for one man is of one Opinion, another of another about the same thing.

Whether the Rational soul be immortal?

And since we have averred the Rational Soul to be the Form of Man, here arises a Question, whether or no it be immortal? or, *Whether it can without perishing be separated from the Body?* As for us, according to the Tenets of our Religion we hold, that our Soul is immortal; and the Immortality of the Soul is counted one of the Hinges upon which Christian Religion turns. But whether or no it may be proved by Philosophical Reasons, and what *Aristotles* Opinion was concerning the same, hath been carefully enquired into by many.

A thing two waies immortal.

In the first place, this we must hold, as *Scaliger* hath it, *Exercit.* 61. *Sect.* 5. and *Exercit.* 307. *Sect.* 20. that only God is truly immortal, and incorruptible. And therefore a thing may be said to be immortal two waies; either because it cannot perish at al, because it is most simple, and hath its Essence of it self, and depends upon none; and such is only God, and in respect of him al other things may be called corruptible: For although Angels and the Rational Soul, which are said to be immortal after the second way, are never actually corrupted, have no contrary, and are separate from their subject; yet seeing they are not without Cause, and they have not the Cause of their Essence from themselves, but are by another,

and

and by another may naturally come to be no more. For every dependent may be changed by that on which it depends, if it be a voluntary principle, and at the pleasure of the first principle it may be deposed from its Essence wherein it was thereby instated. Now some things are not corrupted, because the Creator wil not have them so to be, who hath created nothing in them contrary, whereby they might be corrupted, nor hath plunged them so in matter, as they can neither be, nor operate without it. And that the Soul of man is of this kind, and that it may be separated from the body without corruption, *Marsilius Ficinus* endeavors to prove by many Arguments, *de Immortal. Anim. Lib.* 5. *Tolet. Lib.* 3. *de Anima, cap.* 5. *quest.* 16. Franciscus Piccolhomineus *Lib.* 2. *de Humana Mente, Colleg. Conimbricens. in tract. de anima separata, disp.* 1. *Artic.* 3. and others.

We shal briefly thus determine the matter: Every thing is known by its operations, and every form discovers it self what it is by its operations. And therefore since the actions of Man are so noble that they cannot proceed from a mortal substance wholly plunged in the matter; it is plainly to be hence gathered, that the rational Soul from which they proceed is immortal and separable from the matter: for the Understanding abstracts and severs things from the matter, and knows without conditions of matter, without quantity, without figure; it understands things free from matter; it is not offended with the multitude and vehemency of the Objects as the Sense is; it can conceive things infinite; and although it knows very many things, it may alwaies know yet more, and can encrease a number though never so great; and not only knows a thing, but also knows it self, and understands that it understands what it doth understand; it can wil and refuse, hath an unsatiable appetite of eternity, knowledg, happiness; which because it cannot be satisfied in this life, it is credible that it shal enjoy another condition wherein those appetites shal be satisfied; also it performs operations without corporeal Instruments. See *Franisc. Piccolhomineus de humana Mente, cap.* 6. *Aristotle* also seems to have been of this opinion, as appears in his Physicks, *Lib.* 7. *cap.* 3. *text* 20 1. *de Anima cap.* 3. *text* 49. *cap.* 4. *text* 64, 65, 66. 2. *de Anima, cap.* 2. *text* 21. 3. *de Anima, cap.* 4. *t.* 3. 4. 7. 12. *cap.* 5. *text* 19. 20. 7. *de part. animal. cap.* 1. 12. *Metaphys. t.* 17. of which see *Francisc. Piccolhom. Lib.* 2. *de humana mente, cap.* 2. *et sequent.*

Thus far we have shewed how the rational Soul is referred to the body of man: we are now to explain the nature thereof, as it is a principle of operation. Now *Aristotle* expresses the nature thereof, in this respect, in *Lib.* 3. *de Anima*, when he saith; that the rational soul is unmixed. Now the Soul must be unmixed two manner of waies: first, in respect of the Objects, so that it must not have their nature in its essence, but only a power to receive them. For because it ought to know the Objects, and it knows them by receiving them, it must needs of it self be free, unaffected and unmixed, since nothing receives that which it hath already; and that which is within hinders the ingress of another. And this immixture (that I may so speak) is common to the rational Soul with the Senses, which also have not their Objects actually in themselves, but only a power to receive them: save that the senses are respectively unaffected and unmixed, *viz.* with some sort of being, as the sight (for example sake) within colour, seeing they are not conversant about every kind of being: but the rational Soul is quite free from the natures of al other things, as being directed to al things, and its office being to understand all things. *The rational soul is unmixed.*

Again, the rational Soul is after a peculiar manner free from Organs, nor mixed therewith; that is to say, when it operates by understanding or willing, it makes no use of the body, but performs those functions without it. For, inasmuch as to perform the actions which are done in and by the body there is required a certain temper of the qualities (seeing every body any waies tempered and disposed doth not receive every thing) and consequently also a certain Organ; since the several parts of the body have several temperaments; and the rational Soul is not tied to any temper of the first Qualities, nor any waies affected by the qualities, nor is there any proper Organ thereof in the body: we must doubtless therefore beleeve that it depends not upon the body, in respect of its operations, nor that it is after any such manner mixed therewith.

From this other immixture we may gather, what kind of operations those of the soul are. For since in its acting it is no way mixed with the body, and the actions of the body have nothing to do with the action of the mind: it is manifest that the Understanding and the Wil are inorganical faculties, and act of themselves; so that to understand and to wil, are actions proper to the mind; nor doth the mind understand by the body, or any Organ of the body, as by a medium wherewith it acts. The Soul indeed hath need of a Phantasm; *The Operations of the rational soul are inorganical.*

since the Soul while it is in the Body never understands without a Phantasm, *Lib. 3. de Anima, cap. 7.* but it useth the same not as an Organ, but as an object; because an intelligible matter must be presented to the mind by the Senses. And therefore if any have affirmed that the actions of the mind are organical, and that the rational Soul doth use the help of the Brain, Spirits, and Senses, as corporeal Organs, that is not to be admitted save in this sence, viz. that the soul doth not understand while it is in the body, without the foregoing operation of the Organs of the body, and before its own operation: or that in subordinate operations it uses an organ, and needs the brain, and spirit: but while it is in working of it self, or while it purely understands, and purely wils, it needs them not, nor doth it understand by organs, but this mind only is the subject of understanding, as also of the act of willing, which our barbarous Authors cal volition, by a new necessary and fitting word, as *Scaliger* saies, *Exercit. 307. sect. 3.* and *sect. 9.* and though when the Brain is hurt Reason is depraved: yet that is done for no other cause, but that the administring or the subordinate faculties, which are organical and depend upon the constitution of the Brain, are hurt.

The rational Soul hath two proper faculties.

And although the rational Soul be furnished with all those faculties which we have hitherto attributed to the vegetative and sensitive Soul: yet hath it besides two proper and peculiar faculties, whereby it excels Plants and other Animals; the Understanding, whereby we apprehend and know things; and the Wil, whereby we are carried out to such things we understand to be good. And there is a manifest difference betwixt these faculties, seeing it is one thing to know, another thing to desire the thing known; and these two are performed by a several way of working; the former by passion and reception of the species, so that the things may be carried to the mind: but the latter by following, so that the mind is carried and drawn to the object. Finally the diversity of the object severs the power of knowing from the power of willing, seeing we know things as *Entia* or Beings; but we desire them as good.

The difference of the understanding.

The Understanding is therefore actually none of all the other Beings that are: yet it can spiritually receive and know them all. And although in respect of its essence it is one and the same, as being an inorganical part of the soul, which hath no variety from the Organs: yet according to certain respects it is divided into sundry differences. And in the first place *Aristotle* cals one the active Understanding, another the passive, supposing that in our mind besides that which is apt to be made every thing, viz. by understanding, and which is as it were the matter, there is somwhat in the nature of a form which is apt to make all things, that is to say, actually intelligible.

What the active understanding is.

But what the active Understanding or the *Intellectus agens* is, is an obscure point in Philosophy. Very many hold that the active understanding is God, or some Angel who is assistant to a man. But these mens opinion seems to differ both from *Aristotle* and the Truth. For the Intent of *Aristotle* (in *Lib. de anima*) is to speak of the humane understanding, and he plainly in *Lib. 3. de anima, chap. 5.* cals the active understanding a difference in the Soul. Again, that understanding which proceeds from the *Intellectus agens* or active Intellective faculty is in our own power, nor doth it proceed immediately from God or any Intelligence or Angel. Moreover seeing God when he first made our understanding could put as much light into it as he pleased, there is no need that he should alwaies be assisting the same, like some Judg at the Assises, as *Scaliger* saies in *Exercit. 307. sect. 19.* But the active understanding is (according to the opinion of the Philosopher) a difference of our Soul not informing, which of things potentially intelligible makes things actually understood. For as to a natural affect there is required an agent of the same kind, and for artificial effects there is need of Art: so for the work of the mind, viz. Understanding, an agent is required, not separate from the Soul, but which is a part, or some difference of the soul.

And although this Agent Understanding seems to some unnecessary, who would have it banished out of natural Philosophy: yet it seems altogether necessary to hold an Agent Understanding, for this cause, seeing every thing that is done is done by somwhat and in somwhat, so that *that by*, and that *wherein*, do differ. Universals are made in the passive understanding, therefore there must be besides it another power to make Universals. For since every Patient requires some Agent, and nothing in nature brings it self from power to act; and our understanding is constituted in a possibility actually to understand, and by receiving intelligible objects doth actually suffer: cleer it is, that holding a passive understanding, we must withall hold an active, and taking away the latter we deny the former. The Agent understanding therefore is for this cause necessary, that it may do or make all things, viz. as to their intellectual being, that is, that it may transfer the object from one order to another. For seeing the Object or Phantasm is material, and so under an

opposite

opposite condition to the intellective faculty, which is abstract from all matter; it cannot be by the said faculty understood, unless it be made proportionate thereunto, viz. abstracted and immaterial: now this cannot be done save by an abstract Virtue, and an Intelligent nature.

The Office of the active understanding

From whence it is apparent, that it is the Office of the active understanding to act, that is to draw from power to act, and of things potentially intelligible to make things actually intelligible. This Office of the understanding *Aristotle* expresses by the analogy it bears to Art, Nature, Habit, Light. For it is as it were the eye and light of the mind, and it is to the Phantasms, as light to colours. For it illustrates the Phantasms, being inveloped with material conditions, which like darkness do hinder their being understood, so as they may put on the nature of things intelligible, and may be diffused to the passive understanding: even as Colours by means of Light do send forth a Picture of themselves unto the sight: yet this illustration of the Phantasms is not performed formally, so that any quality is imprinted upon them; nor objectively only, but effectively; because the Agent understanding like external light by imparting its Ray yet doth actively elevate the Phantasms, to the production of an Intelligible species; nor is the Agent Understanding requisite only in respect of the object, but it hath also another office, viz. in reference to the passive understanding, that it may produce therein the act of understanding, representing thereto an object in a species intelligible, which it performes when together with the illustrated Phantasm it produces a species of the thing to be understood, into the passive understanding.

The Subject

Whence we may collect, upon what and how the Agent understanding doth act. For it is requisite in respect of both actions, viz. that it may act upon the Phantasms, and upon the passive understanding. But it acts upon these in a different manner; for it is joyned to the Phantasms before Intellection, and indeed while they are yet in the Fancy, where illustrating them it becomes their form, whereby they are made a moving object of the passive understanding: afterwards, the adjoyned Phantasms being illuminated, it acts upon the passive understanding, by producing therein an intelligible species or representation, and by consequent the act it self of understanding: But the Agent understanding it self as it is an Agent doth not understand; since it doth not receive the intelligible speces or notions, though it produce them, nor is in aptitude to understand; but the act of understanding is in the Passive Intellect, as in its subject. This therefore is called formally the Intellect; the other only effectively, because it makes the understanding or Intellection.

The passive understanding what it is.

The Passive understanding is as it were the subject and matter, whereon the intelligible species are imprinted; and therefore 'tis called Patient and Passive, because it suffers by receiving the species, through means of the Phantasms. It is also called *Intellectus possibilis*, the possible understanding, and the mind in power; because it may be made all things, though it is actually none of them.

And here in the first place we must remember that the passive understanding is indeed in respect of the object a passive power; seeing it acts upon no other thing: but compared with the Intellection it is a power, both active, inasmuch as it works Intellection; and also passive, inasmuch as it receives the said Intellection. For an immanent action must be received in the same power by which it is produced.

Moreover we must observe how that it is to be understood that *the understanding when it understands, is made all things*, which in the most elegant words of *Scaliger*, *Exercit.* 307. *sect.* 6. thus we explain. *In the first place* (quoth he) *I deny that the Philosopher saith, that our understanding is all things essentially or formally as they use to say. But it is all things, subjectively, even as the first matter is, which is not made the Essence of an Horse under the form of an Horse: but it remains that which it was, a certain substance, of which and the form this thing is made. But the information of the understanding is after another manner: for it is not a meer possibility, as the first matter, which may be reduced to be actually this or that by the form. But it is our form substantial, separable, incorruptible, eternal; of which as a subject essentially perfect, and the species which it receives, is made the formed intellect, not another from it self; save as* Cæsar *being learned differs from himself unlearned, by reception of accidental species. It is not therefore made the understanding simply, nor is it made the species it self, but under the species.* So far *Scaliger.*

The Agent & passive Intellect do not really differ.

And so much shal suffice to have said of the first difference of the understanding: where this again is to be observed: that the Agent and passive understanding are not really and essentially distinguished, but only respectively; since two internal forms are not knit together by new accidents, and to the receiving and effecting of an immanent action (such as understanding

ſtanding is) ſuch a principle is requiſite as is eſſentially one. And therefore we muſt conclude that the Eſſence of the Agent and Paſſive Intellect is al one, and that one Underſtanding in Eſſence, inaſmuch as it makes things intelligible, or illuſtrates the Phantaſms, and repoſits them in the Paſſive, is Agent; but inaſmuch as it is the ſubject receiving the abſtract Phantaſms, it is called the Patient.

the Underſtanding in habit:

Beſides the Differences reckoned up, there are alſo other notions of the Underſtanding, as the Underſtanding in habit, and the Underſtanding in act; which indeed are not divers Underſtandings, but one that hath divers degrees, which *Ariſtotle* cals differences. For the Intellect in habit is that which hath the Phantaſm reſerved in the Phantaſie; and it is in a more perfect degree than the poſſible Intellect: for this is in aptitude to the firſt act, the other is in aptitude to the ſecond, or to the operation, and therefore is very like to him that hath ſcience, and does not contemplate. Howbeit *Zabarella* ſeems to think otherwiſe in this point, *Lib. de ſpecieb. Intellect. cap.* 8. after this manner; That our mind is firſt born rude and unfit for the knowledg of things; but afterwards by multiplied acts of Underſtanding it acquires a certain greater ability and aptitude to underſtand things, ſo that it can without any labor when it pleaſeth turn to the Fancy, and preſently underſtand a thing: and that the Underſtanding being furniſhed with this ability is called the Intellect in habit. But when the Paſſive Underſtanding does actually operate, and actually perceives the thing offered, it is called the Intellect in act.

the ſpeculative and practical underſtanding:

Finally, the Underſtanding is diſtinguiſhed into Speculative and Practical; by which terms nevertheleſs there are neither made two faculties of underſtanding, nor are the differences and degrees of the ſame Faculty intimated; but each Faculty of the Intellect is ſignified by the Theoretick or Speculative, the Underſtanding properly ſo called, and by the Practical the Will. For ſeeing the Underſtanding in reſpect of the apprehenſion of a thing, alſo in reſpect of Affirmation and Negation of that which is true or falſe, cannot be otherwiſe called than Speculative; of neceſſity that difference muſt ariſe in reſpect of a third attribute of the Practical Underſtanding, viz. Deſiring and avoiding, which belong to the Will.

the Operation of the underſtanding:

The operation of the Underſtanding to which al the Functions of its degrees do tend, is Intellection, which is not one and the ſame thing with the Intelligible Species, but really differs therefrom, and is more rightly defined by reception of Intelligible ſpecies (in which ſenſe it is by *Ariſtotle* termed a kind of Paſſion, 3. *de Anima, cap.* 4.) and paſſing judgment thereon. For the Intellect exerciſes a twofold operation about its object; the former of which is ſimple Apprehenſion and Cognition; but the other is termed Compoſition and Diviſion, and it is compound Apprehenſion and Judgment, which conſiſts in Aſſent and Diſſent. And hence Intellection is ſaid to be twofold; Simple when the Intellect knows that which is ſimple and incomplex, as they cal it: and Compound, when it knows a propoſition true or falſe.

Intellection is twofold:

The Object of Intellection which at once moves and terminates the intellect, is a Being or thing Univerſally taken, comprehending things material and immaterial. To which nevertheleſs ſome conditions muſt needs be added. And in the firſt place Univerſality: For that a Being may be perceived by the Intellect, it muſt be abſtracted from al ſingularities. Then Secondly, Intelligibility, or abſtraction from the conditions of matter. Thirdly, Verity. This Object as it is fitted and proportioned to the Mind by the Agent Intellect, is called an Intelligible Species; as that which the Senſes receive is called a Senſible Species.

Intelligible ſpecies what they are.

Now the Intelligible Species are illuminated Phantaſms, that is to ſay, freed from the conditions of matter, and by the Agent Intellect imprinted upon the Paſſive, and conſequently ſpiritual and indiviſible accidents: For a Subſtance is not received into the Senſe, as *Scaliger* would have it, *Exercit.* 303. *Sect.* 7. but only accidents. And therefore only accidents do make the Species or Image in the Intellect; amongſt which are both time and place, and the finite Unity of quantity, which being removed by the operation of the Intellect it ſelf, there remains an Univerſal ſubſtantial Species: As if you ſee a man armed and diſguiſed; firſt you apprehend the Arms the diſguiſe, and afterward having removed them you conceive the Man himſelf.

Whether or no, and how the underſtanding perceives particulars?

And ſince we have juſt now aſſerted, That ſuch things as are offered to the Intellect, and received by it, muſt be ſeparated from matter and al particular conditions, the Queſtion is; How the Intellect underſtands particular things, or whether it be capable only of univerſals? We anſwer, That the Mind of Man does alſo know particulars. For ſince al knowing Faculties being ſubordinate, are ſo joyned that the end of one action is the beginning of another,

ther, and what ever is known by the Inferior Faculty is also known by the Superior; and the Senses and Fancy know particular things, the Mind also must needs know the same. And by means of this knowledg it comes to pass that a man is able to compare a singular with an universal, and that the mind can frame singular propositions, collect universals from them, and frequently correct the judgment of the Senses about singular things, viz. As oft as they (by reason of an evil disposition of the Object) do commit any error. Now the manner of knowing singulars is also by accidents; because out of the proper singular accidents we draw out a notion or phantasm proper to the single Objects; even as out of the notions proper to a sort we draw out a notion proper to the same sort.

Understanding Direct. *Reflex.*

Intellection is commonly divided into direct and reflex. It is termed direct, when we only know somwhat, and make no further enquiry, but the Species gives a stop to the Intellect, as when the Understanding staies at the first apprehension of a Man, an Ox, an Horse, &c. but that is termed Reflex, or doubled and reciprocal as it were, whereby the Mind knows it self, viz. That it knows, and hath the power to know and Understand; or when we understand the Intellection it self, and the Understanding knows that it is an Understanding, viz. That it self is an Essence and an unmixt one, and knows that it understands, because that it is able to know it understands.

What it is to abstract

And here you must observe, what it is to abstract. Now Abstraction is the separation of one thing from another, and the apprehension and understanding of one thing without the apprehension or understanding of others. For in Abstraction al things are not known which are in a thing, but that only which is abstracted: for examples sake; To abstract the Living Creature from the Horse, is to consider only the Nature of a living Creature in general, not regarding the particular Nature of an Horse.

The will what it is.

Finally, The Will (that we may also speak briefly thereof) is the other Faculty of a Rational Soul, whereby we follow or avoid such things as are known by the Understanding; or (as *Scaliger* hath it, *Exercit.* 307. *S.* 3.) The Will is the Understanding extended to the having or doing what it knows. Others cal it the Rational Appetite. For as after the knowledg of Sense there follows a Sensitive Appetite; so after the knowledg of the Mind an Appetite follows proper thereto, which to difference it from the former, they cal it *Voluntas*, the Will; and that this Rational Appetite differs from the Sensible is hereby apparent, because they are frequently at enmity one against another.

The object of the will. *Its actions twofold.* *1. Drawn out.* *2 Commanded.*

The Object of the Will, is *Good* known by the Understanding and presented to the Wil, and the contrary Evil: Hence it follows the Good, and shuns the Evil. The Actions of this Faculty are to Will or Desire, and to Nill or Refuse. Now the Actions of the Will are twofold; *Drawn out*, and *Commanded*. The *Drawn out*, are those which the Will puts forth and performs of it self, and not by the inferior powers. The *Commanded* are those which the Will commands and enjoyns the inferior Faculties to perform. Now the Will hath command over the Locomotive Faculty, and the Sensitive Appetite: for at the word and command of the Mind and Will we move and rest. But the command which the Will ought to have over the Sensitive Appetite is much weakened by sin, and that same harmony disturbed betwixt the two Appetites; so that many times the Sensitive Appetite casts off the command of the Will and right Reason, and that saying becomes true:

Hurry'd the Coach-man is, and the Coach away, by the Horses.

But the Will hath no command over the Vegetative Faculty, and it acts meerly naturally, nor can we be nourished or grow according to our own will and pleasure.

Chap. 2. *Of the Body of Man, and its Functions.*

NOW the Soul of Man, since it is the Rule (in a manner) of al things living, as *Scaliger*, *Exercit.* 102. *Sect.* 5. hath it; it must also of necessity have the most noble Body of al; which ought now to be described, as the Rule of all the rest. But since the dignity thereof, yea, and the necessity that there is of its knowledg, hath stirred up many to seek the knowledg thereof, so many Volums are written concerning the same (wherein both its parts are accurately described, and the uses of al of them laid open) that it is an impossible thing to Epitomize the same. To name a few Authors: *Galen* hath written many Books of this subject; of the Dissection of the Muscles, Nerves, Veins, Arteries, vocal Instruments, Womb, of the Bones, of Anatomical Administrations, 9 Books; of the use of the Parts, 17 Books, and others. Very many men of this Age have diligently written of Anatomy, amending

amending and encreasing the Doctrine of *Galen.* And amongst them chiefly *Vesalius, Fallopius, Columbus, Sylvius, Piccolhomineus, Laurentius, Platerus, Bauhinus, Casserius, Fabricius, Riolanus, Spigelius,* and very many more, all whom to reckon up the Nature of this short work will not permit. We shal therefore in this place only with brevity name the Parts of the Body whereby al the actions thereof are performed; the Description whereof may be seen in the Authors aforesaid, which are in the hands of every one.

the disposition of the parts of the body wherein it consists?

Now that the parts of our Bodies may be fit to perform their actions, they must needs be rightly disposed. Now that disposition consists in three things: For since the parts of our Body are considered either as similar only, or as dissimilar and organical; in both of them Unity is required, and it is necessary that every part be one and entire. Moreover, particularly in the similar parts there is required temper; in the organical composition and conformation, necessary for the actions of the Body; which is in divers parts different, according to the diversity of the actions by them to be performed.

the Constitution of the similar parts.

the temperament of a Man, twofold.

Now what in general a Temperament is, and what are its differences, hath been already declared in Book 3. chap. 4. But as to what concerns the Temperament of a Man, in him (as also in other Creatures, of whom he is as it were the Rule and measure) is found a twofold Temperament; the one of a Body, considered simply as a mixt Body; the other of a living Body. For when a man dies, that temper which he had as a living body does withal vanish; yet in the Carkass til it rot the parts do for a while retain the composition and temper which they have from the Elements.

Each part hath a peculiar temperament.

Concerning the Temper of a mixt Body we spake before in the Book newly cited: but the Temper of a living Man, which results out of a certain harmony of al his parts, although it be hot and moist, and Life consists in Heat and Moisture; yet there is a great diversity in the Parts. The Skin is the most temperate, especially that in the Hand.

Hot parts:

Among the Hot Parts the chief is the Heart: after the Heart follows the Liver, the Spleen, the Flesh of the Muscles, the Kidneys, the Lungs, a Vein, an Artery, Fat and Suet.

Cold parts

Among Cold Parts, the first are the Bones, then the Grisles, the Ligaments, the Tendons, the Membranes, the Arteries, the Veins, the hard Nerves.

moist parts

The Moist parts are, Suet, Marrow, Brain, Spinal Marrow, Stones, Dugs, Lungs, Spleen, Kidneys, Flesh of the Muscles, Tongue, Heart, soft Nerves.

Dry parts.

The dry are, Bones, Gristles, Ligaments, Tendons, Membranes, Arteries, Veins, hard Nerves.

the inbred Heat wherein it consists.

Now this Temperament of a living Body is twofold, or consists in two things; Innate, and Influent Heat. Innate Heat is in that which is the inbred hot juyce natural: For by innate heat we understand not a bare quality, but a quality with its subject. This Innate Heat consists of the inbred Spirit and original moisture: and is nothing but the Primitive Moisture filled in al parts with the implanted spirit and heat. For these three, Heat, Spirit, and Radical Moisture, or Natural Balsam as some cal it, are so joyned together, as that they cannot be easily separated. For this is that Body *which is more Divine than the Elements so called, and is a substance bearing proportion to that of the Heavenly Bodies,* as *Aristotle* terms it in his 2. *de generat. Animal. cap.* 3. and by which the seeds of things are made fruitful, as the same *Aristotle* informs us.

the Subject of the inbred heat:

This inbred heat is principally in the Spermatick Parts, which are called the first Parts. But it is chiefly found in the Heart, which therefore *Galen* cals the Hearth or Chimney of the inbred Heat. And this innate Heat is the chief instrument of the Soul, whereby it performs and perfects al actions. At the beginning of a Mans Life, and in his yonger yeers, it is much in quantity; and as he grows older, the Radical Moisture is gradually consumed and dried up, til at last being quite spent, the Heat is also extinguished, and natural Death follows.

what the spirits in the body are?

Now this inbred Heat is cherished and fomented by the influent Heat, through means of the Spirits, which are a most thin, hot, and movable body, bred of the most sincere and subtil part of the Blood; and being joyned with the inbred Heat they are the immediate and chief Instrument of the performance of al actions, and are a cause that the faculties of the Soul exercise their operations.

they do not conveigh the faculties:

'Tis commonly taught by many, That these Spirits are the conveighers of the Faculties from the principal Parts to the rest of the Body: but this is a false Opinion. For seeing the Faculties are inseparable Properties of the Soul, and the Soul is in all the parts, it is every where furnished with its Faculties, not borrowing the same elsewhere.

the number of the Spirits:

Now touching the Number of these Spirits, several men are of several Opinions; and some

make

make one, and others more. But we have reason to hold that there are divers Spirits. For although the more subtile part of the Blood be the first matter of them all; yet they receive a diverse form in sundry parts, and are fitted for divers uses.

Now the Spirits are three, Natural, Vital, and Animal.

The Natural:

Touching the Natural many doubt. We although we admit them into the number of Spirits, yet we acknowledg no smal difference betwixt it and the other Spirits, and that the name of Spirits does not so properly belong to them as to the others, nor that they have the same Office. Now it is generated in the Liver, and is contained in the Veins, and is the thinner and more spirituous part of the blood, bred of the vaporation of the blood, and affords matter to make the Vital Spirits of.

the Vital:

All grant a Vital Spirit, which is generated in the left Ventricle of the Heart of the thinner part of the Blood, or Natural Spirit, flowing into the Heart, and first of al attenuated and elaborated in the right Ventricle; and of the Air drawn in by breathing, and by the dilatation of the Arteries. This Spirit is not only in the Heart the chief Instrument thereof, together with the inbred heat of the Heart; but also being spred abroad through the Arteries into the whol Body, it cherishes the inbred heat of al the parts, excites and encreases the same, and gives perfection as it were thereunto. And therefore some call it the influent Heat. Also this Spirit affords matter for the Animal Spirits.

the Animal:

Many indeed deny the Animal Spirit; yet we have reason to admit the same, seeing it is wrought in a peculiar Member, viz. The Brain, nor can the Vital spirit perform those uses which the Animal does, and in a part ful of Vital Spirit we see sense and motion taken away for want of Animal Spirits, as in the Apoplexy, Palsey, and stupidity.

For this Spirit is the immediate Instrument of Sense and Motion; and it is generated of the purest part of the Vital Spirit, carried by the Carotick and Cervical Arteries into the Basis of the Brain, and thence into the Brain it self, and mingled with Air drawn in by the fetching of breath.

the Constitution of the Organick parts:

Moreover, The Organick parts have also their proper Constitution, viz. A due composition and connexion of the similar parts into one form and shape, fit to exercise the action. Now there is required to the composition of Organick parts; first a just number of parts compounding; secondly, the greatness fit for the said parts; thirdly, a decent conformation, which comprehends a figure fit to perform the action, cavities and passages, and that the surface be rough or smooth, as the Nature of the part requires; fourthly, scituation and connexion with other parts.

These things whereof we have hitherto spoken being common to al parts, and necessary for al actions; we will now furthermore briefly recite how and by what parts the several actions are performed.

And seeing the Vegetative Faculty is the lowest, we wil first treat thereof. Now it contains under it, Nutrition, Augmentation, and Generation.

And as to Nutrition and Augmentation in the first place, seeing in them Aliment is joyned to the Body from elsewhere (and the Aliment is in the first place unlike of substance) it must be elaborated by divers Concoctions, and be first made fit for the Body.

A double Concoction in the body private & publick.

This Concoction is twofold; Private, which is performed in the several parts; and Publick, which is ordained for the use of the whol body, and is performed in the stomach chiefly, and in the spleen.

the first Concoction

The first Concoction therefore is performed in the stomach; and for the same cause a double Appetite is given to the stomach; a Natural, whereby it desires food for it self alone; and an Animal Appetite, whereby it desires food for the whol body.

For by Appetite and hunger a Man is pricked on and provoked to eat, and then the first preparation of the Meat is in the Mouth. For in the Mouth it is by the Teeth broken and ground; which for that cause (although they serve also to form the Speech) are given to a man commonly thirty two in number, in each Jaw sixteen; of which some are called Cutters, others Dog-teeth, others Grinders. The Cutters or foremost are four in each Jaw; the Dog-teeth two; the Grinders ten. Moreover, by the Mouths heat, and the mixture of spittle, the meat is altered. The Meat being thus broken, ground, and prepared in the Mouth, is by the Tongues motion thrust down the gaping Throat into the Stomach, which the stomach by help of the oblique fibres does imbrace and retain til by the Concoctive Faculty thereof and its proper heat it be turned into a Mass not unlike Barley Cream, which is called *Chylus*.

the making of Chyle.

The Chyle being wrought in the stomach is sent out by the lower Orifice into the Guts, and is by them stil more elaborated. Now the Guts are of two sorts, the Thick and the thin:

Distribution of the Chyle:

thin: The thin are three, *Duodenum*, *Jejunum*, *Ileon*; the thick also three, *Cœcum*, *Colon*, *Rectum*.

the Excrements of the first digestion.

And seeing no Meat can be turned wholly into Nourishment, but hath some parts in it unprofitable to nourish the Body: Nature in this, as all other Concoctions, separates what is unprofitable, and breeds here a two-fold Excrement, the one thick, the other watterish.

the Dung

The thicker Excrements are the Dung, whose expulsion is through the Belly by stool: the Guts partly by their circular and transverse fibres (with both which both their Coats are furnished) contracting themselves above the same; partly by help of the Muscles of the Belly, whereby the Belly is squeezed; and so the Excrements are forced downwards.

The thin and watry excrement.

The thin and watterish Excrement is not presently voided forth, but remains mixed with the Chyle, that it being thereby made thin may the more easily pass the narrow Veins of the Mesentery and Liver.

The second Concoction, or blood-making.

The first Concoction being finished, the Chyle is received out of the Mesaraick Veins, (whose Orifices reach into the Guts) is altered and changed a little, and is hence carried to the Roots of *Vena Porta* and to the Liver.

And that the blood may be bred more pure in the Liver, after the Blood hath received some rudiment in the Mesaraick Veins, that which is therein thick and dreggy is drawn by the Spleen through the Splenick Branch of the *Porta*, out of the Trunk of the Mesaraick Veins before it pass to the Liver; where the Spleen alters it as much as it can and the matter will bear, and thereof breeds for it self and the ignoble parts in the Belly a thick and dreggy blood. But that which is quite excrementitious, and cannot be turned into Aliment is evacuated, partly by the Hemorrhoidal Veins and *Porta's* Trunk, and partly by the Splenick Arteries.

The Chyle after it hath received some rudiments of Blood in the Mesaraick Veins, and is by help of the Spleen purged from the more dreggy parts thereof, it receives the form of perfect Blood in the Liver; and is thence distributed into al the parts of the Body to nourish the same.

Excrements of the second digestion.
1. Yellow Choler:
2 Urine

And since in every digestion Excrements are bred, there is also in Sanguification a two-fold Excrement; yellow Choler, which is collected into the Gall-bladder, and is thence voided by the Guts, exciting them by its acrimony to purge themselves: and the serous or wheyish excrement, which is drawn through the Emulgent Veins by the Kidneys, and is transmitted through the Ureters into the Bladder, and is by it voided forth and called Urine. For the Urine is nothing else but that watry moisture in the Chyle that served to make it pass more easily, and the salt which was superfluous in the meat and unfit to nourish the Body. Which appears not only by the taste, but also becaufe store of salt is drawn out of Urine, the watry moisture being separated.

The blood consists of divers parts:

The Blood which is distributed into the whol Body to nourish the same, although it is contained under one form or shape, and is al useful to nourish the Body; yet its parts are not quite alike, but some temperate, which are peculiarly called blood; others hotter and drier, which are called Cholerick Blood; others colder and moister, which are called Flegmatick Blood; others colder and drier, which are called Melancholy Blood; but vulgarly these parts are called, Choler, Flegm, and Melancholy.

And of these parts none is Excrementitious, but al are useful to nourish the Body; and in the Body of a sound Man there is nothing Excrementitious, but only Alimentary blood is contained in his Veins, and al the parts of our Bodies are nourished only with blood.

the third concoction

This Blood in the several parts is elaborated according to the Nature of each part, and at length assimilated to the said parts. And seeing in that elaboration the blood undergoes some mutations, Physitians do say, that in the third Concoction the four secondary humors are generated; whereof the one follows the other, and by these mutations the blood is turned into the substance of the Body. The first is called the Nameless, the second Dew, the third Glew, the fourth Cambium.

the secondary humors.

the Excrements of the 3d Digestion.

In this Concoction two Excrements are generated, the one more gross, which is the filth that gathers about the Skin; the other more thin, which is discussed, partly by invisible transpiration, and partly by sweat. For the evacuation of which excrements the Skin was furnished with pores.

the generative faculty.

Moreover, That a man might propagate and multiply himself, he received from the Creator the Faculty of Generation. Now Generation is caused by seed elaborated in the stones, unto which out of the rest of the Body the best part of blood, spirit, and heat, is transmitted by the Veins, Arteries, and Nerves; and is by them reduced into a white froathy body,

full

ful of ſpirits, which is called ſeed and is a compendium as it were of all the Heat and Spirits in the Body.

This Seed is ſent forth both by the Man and Woman: for ſeeing Women are furniſhed with the ſame Inſtruments, both to make and vent Seed; and when they are provoked by Luſt they deſire Copulation, and void ſeed: we muſt needs grant that they contribute ſeed to Generation. And their ſeed goes to the making up of the Child: for the male and female are not two ſorts of Creatures: yet neither of their ſeeds is alone ſufficient for Generation, but this order is appointed by the Creator, that of both their ſeeds as two partial cauſes, one principle and one total cauſe ſhould ariſe, from which one motion (though in a certain orderly diſpoſition) ſhould further the production of the Child.

The Seeds conceived in the Womb are by the inbred faculty thereof cheriſhed, and the faculty lurking in the ſeed is ſtirred up, and the ſhape of the Organs begins to be expreſſed; and ſo conception is ſaid to be made, and then it is termed a Conception. Now the membranes encompaſſing the Child are firſt formed, in which the nobler part of the ſeed and ſpirit is included; and they are two, one called *Chorion* compaſſes the whol Child, props up the umbilical veſſels, and by their their means it totally adheres to the Womb: the other immediately compaſſing the Child is called *Amnios*; which Coats ſeeing in the Birth they ſeem to be but one, are termed the After-birth, becauſe they come away after the Child.

Now the ſpermatick parts are firſt formed and that all at once. And afterwards every part is finiſhed, as the dignity and neceſſity thereof requires. At firſt there appear as it were three bubbles, and innumerable threds, being the underwoof of the ſolid parts. Theſe parts do afterwards receive encreaſe from the mothers blood. And hereupon the Creator hath ordained, that from the fourteenth yeer commonly of a Womans age, to the five and fiftieth, there ſhould be ſome ſuperfluous blood as it were, bred in women, and afford matter for the Child in women that have conceived: or if a woman be not with Child that it ſhould be ſent unto the womb, and from thence purged away.

Since therefore the Child after it is once formed in the Seed is furniſhed from the mother with all things it ſtands in need of, there were navil veſſels made, viz. a Vein, two Arteries and the *Urachus*, which about the navil grow together into one. The Vein is a branch of *Vena Portæ*, to which it is contiguous, being the Nurſe (as it were) of the Infant: the two Arteries (branches of the *Ramus Iliacus*) deſcending do ſpring from the *Aorta*; whereby arterial blood and ſpirit are communicated to the Infant, and by which the Infant draws breath. The *Urachus* is carried from the bottom of the Bladder to the Navil; when the Child is born, there being no longer uſe of theſe Inſtruments for theſe intents, they grow together, and perform the office of the Ligaments as it were.

The Navil-veſſels
The Vein.
The Arteries.
The Urachus.

Now the whol time from the Conception to the Birth is divided by Phyſitians into two parts; the time of formation or ſhaping, from the Conception to the time the Child begins to ſtir; and the time of perfection, which is from the time it begins to ſtir, to the time it is born: yet others divide it into three parts, viz. into the time of Formation, which *Hippocrates, de natura pueri*, determines to be of Girls in forty daies, of Males in thirty: the time of motion which is commonly ſaid to be of Males in the third month, of Girls in the fourth: and thirdly, the time of birth.

The time of Formation.
The time of Motion.

Now as to the time of birth, that is various in mankind: yet experience teaches, that no Child is born alive before half a yeer be paſt. The Child born in the ſeventh month may live: but no Child born in the eighth month can live according to *Hippocrates*; yet ſome hold that the eighth months Child does ſometimes live. But the moſt orderly and frequent time of childing is the ninth month, and moſt Children are brought forth from the 15. of the ninth month, to the 15. of the tenth.

The time of Birth.

And although Phyſitians have obſerved that ſome have been born in the eleventh month and after the eleventh month: yet ſuch births are to be reckoned amongſt rare accidents.

How the months are reckoned.

Now the months according to which the times of Child-birth are reckoned are the ſolar months, or months of the Sun; from which nevertheleſs the lunar Conjunctions (conſiſting of twenty nine daies and twelve minuts) do not much vary. Nor muſt this laborious frame of mans body be tied to ſuch ſmal obſervances of time.

After the Natural faculty comes the Vital, being diſtinct from the Natural and Animal, both in actions and peculiar organs, and hath its ſeat in the Heart. Now under the term of vital faculty divers powers are comprehended; and there are in the Heart three faculties, the Wrathful, the Breeder of ſpirit and vital Heat, and Pulſing faculty which is ſubſervient hereunto.

three faculties in the Heart

the wrathful faculty From the wrathful faculty proceed al the passions of the mind, Anger, Manfuetude, Boldness, Fear, Hope, Dejection, Joy, Sadness, and others of this kind which follow the former. Now some of these are caused materially (that I may so speak) or in way of an efficient cause, by expansion of the Heat, Spirit and Blood, as Anger, Joy, and the like; some by the Concentration or gathering inward of the said Blood and Spirits, as Fear, Sadness, and the like: and formally they are all no other than Appetites; and these motions do follow an appetite, either of prosecuting that which delights, or of avoiding that which is hurtful; the former of which causes an expansion or spreading abroad of the Heat and Blood, and the latter causeth them to retire inwards. Now these motions cannot be made, save by agitation of the Heart and Arteries, and of fervent and spirituous Blood. Whence it is apparent why the wrathful faculty needs a very hot Bowel, and which is in continual motion.

Now the Heart is seated in the middle region of the Body, viz. in the Chest, that from it as a fountain the vital heat and spirit may readily be diffused into the whol Body. Now the Heart hath two Ventricles, the right and left: the right Ventricle out of the wide mouth of the *Vena cava* draws in Blood by its Diastole, which it perfectly concocts and attenuates: the thinner portion whereof is transmitted into the left Ventricle of the Heart, by those holes in the partition wall betwixt the two Ventricles; which nevertheless some deny: but the remaining and greatest part passes through the *Vena arteriosa* into the Lungs; some part whereof is spent in nourishing the Lungs, but for the greatest part is carried through the *arteria venosa* into the left Ventricle of the Heart.

the use of the Heart and its Ventricles.

the motion of the Heart. Now these things are performed by a certain wonderful and perpetual motion of the Heart, whereby in the Diastole its extream parts are contracted, and the point of the Heart is drawn to the Basis, and so the Heart becomes more short, but the sides thereof are dilated: but in the Systole the Heart becomes longer, and narrower. And seeing for the breeding of spirits and Arterial blood there is need both of Air and Blood, and these two substances cannot be drawn with one motion: besides the Ventricles which draw the Blood, on each side at the Basis of the Heart there are two notable cavities, ending into the upper part of the Ventricles, which by a peculiar motion of their own do draw to themselves Air to cherish the Spirits and fan the vital Heat, which are termed the Hearts Earlets. For although others say their use is to be as it were Store-houses of the Blood and Air flowing in, and guard the *Vena cava*, and the *Arteria venosa*: yet some conceive, that by a peculiar motion they draw in Air; and *Hippocrates* himself, *Lib. de corde*, holds that they cool the Heart like a pair of Bellows.

the Pericardium. And that the Heart may not be hindred in its motion, it hath allotted unto it a large and membranous Mansion, which they cal *Pericardium* the Heart-bag, which hinders any thing from pressing upon the Heart or troubling the same in its motion.

the four Vessels of the Heart. But seeing nothing could go into or come out of the Heart unless it had been furnished with certain conveighances: therefore in the Basis of the Heart four remarkable Vessels are seen, two in the right, and as many in the left Ventricle: In the right, the *Vena cava*, and the *Vena arteriosa*; in the left, the *Arteria magna*, and the *Arteria venosa*. The *Vena cava* is at the right Ventricle of the Heart, and pours Blood into the Heart, for the Generation of arterial Blood and vital Spirit and the nourishment of the Lungs. Howbeit others think the Blood which is wrought in this Ventricle is also distributed through the whol Body. Then there is the *Vena arterialis*, which carries blood out of the right Ventricle to the Lungs for to nourish them, as also to become the matter of arterial Blood and vital Spirit; the *Arteria venosa* carries Air from without and prepared in the Lungs, and Blood brought out of the right Ventricle of the Heart by the *Vena arteriosa*, into the left Ventricle, and expels smoaky exhalations, and distributes a portion of the vital Spirit into the Lungs. Finally there is the *Aorta* or *Arteria magna*, which distributes the vital Spirit and Arterial Blood bred in the left Ventricle through the whol Body: And these are (as *Hippocrates* sales) *Pegai Phusios Anthropou*, the *Fountains of the Nature of Man*.

Vena Arteriosa.

Arteria venosa

Arteria magna:

the Valves And seeing these Vessels have each of them two uses (for examples sake, the *Arteria venalis* doth not only draw Air out of the Lungs into the left Ventricle of the Heart, but it communicates vital spirit and arterial blood to the Lungs, and expels smoaky vapors) lest the substances entring the Heart should fal back the same way they came in before they have gained their perfection, or that which is shed out of the Heart might return thither again, there are eleven Valves placed in the orifices of the Vessels; three in the orifices of all the other Vessels, and only two in the *Arteria venosa*: Of which Valves some are open outwards and shut towards, namely those that pass the matter to the Heart; others are open within,

that

ſhut without, being ſuch as paſs matter from the Heart. In the orifice of the *Vena cava* are three Valves, open outwardly, ſhut inwardly; contrariwiſe, in the orifice of the *Vena Arterioſa* there are as many open within, ſhut without: in the orifice of the *Vena arterioſa* there are as many, open within ſhut without: in the orifice of the *Arteria venoſa* there are two, which are open without, ſhut within; in the orifice of the *Arteria magna* are three Valves, open within ſhut without.

the Branches of Arteria magna.

And becauſe the Heart diſtributes Heat and Spirit through the Arteries into the whol Body, there are paſſages made to carry the ſame, viz. the Branches of the great Arterie, which themſelves alſo are dilated and contracted, and by the pores of the Skin draw in Air, expel ſmoaky vapors, and communicate to the whol body vital Spirit, Heat, and Arterial Blood; and this motion of the Heart and Arteries is termed the Pulſe.

Of what motions the Pulſe doth conſiſt.

Now the Pulſe conſiſts of two motions, Syſtole and Diaſtole. By the Diaſtole or dilatation the Heart is filled, and draws Air and Blood out of the Lungs by the *Arteria venoſa*; and the Arteries by their orifices, which end in the Skin, do draw ſome of the ambient Air: but by the Syſtole or Compreſſion the Heart diſtributes vital Spirit and Heat through the whol body, by the *Arteria magna*, and expels fuliginous excrements to the Lungs, by the *Arteria venalis*: alſo the Arteries expel fuliginous excrements by their orifices, which action is termed *adelos diapnoe*, inſenſible Tranſpiration.

the chief Organ of Reſpiration.

But becauſe the Air, which is drawn by the Heart, was to be altered before it came thither, therefore the Lungs were given, and Reſpiration ordained. The chief Organ of reſpiration is the Lungs. For although the Cheſt and other parts do alſo ſerve for reſpiration: yet that motion is primarily performed by the Lungs, which have a peculiar faculty to dilate and contract themſelves, as the Heart and Brain alſo have: which may eaſily be obſerved in the diſſection of Live-anatomies. Nor is reſpiration a voluntary motion, ſo that the Lungs ſhould dilate themſelves upon the motion of the Cheſt, to avoid *Vacuum*; but the Lungs are moved by a proper power of their own, and the Lungs and Cheſt are moved together, becauſe they conſpire both to one end. For the Lungs by an inbred faculty are dilated: and that it might be done more conveniently, and that it might have room wherein to dilate it ſelf, when the Lungs move, the animal faculty at the ſame time moves the Cheſt. And indeed theſe two motions hold proportion one to another. Nor are the Lungs diſtended becauſe they are filled, as a Bladder that is blown up; becauſe Air is not from any place blown into the Lungs: but they are filled becauſe they are dilated, after the manner of a pair of Bellows.

Reſpiration no voluntary motion.

Reſpiration made up of two motions.

Now reſpiration conſiſts of two Motions, Inſpiration and expiration. By Inſpiration the Lungs and Cheſt being widened, Air is drawn in by the Mouth and Noſtrils for to cool the Heart and to make vital Spirit: and by Expiration, the Lungs and Cheſt being compreſſed, fuliginous excrements are voided at the Mouth and Noſtrils. Hence, that much Air might be attracted and retained therein, the Lungs exceed all the Bowels in greatneſs, and have a rare and porous ſubſtance.

the Aſpera Arteria.

And becauſe the Air was to have an Ingreſs into the Lungs, therefore was the Weſand [*Aſpera arteria*] or Wind-pipe made; whoſe larger Trunk might receive Air, partly by the Mouth and partly by the Noſtrils; and other branches innumerable are diſtributed into all the parts of the Lungs, that they might be totally repleniſhed with Air; which Air the Veſſels coming from the Heart to the Lungs, being large and great, do receive at their ends, and carry it into the Ventricles of the Heart.

And becauſe a man perpetually needs to draw in the Air, the Weſand is made of ſolid griſly rings, that it may be kept perpetually wide and gaping.

the Epiglottis.

But leſt the Meat or Drink in paſſing over the Wind-pipe ſhould fall thereinto, whereby a mans life might be endangered: on the top thereof a ſoft and ſharp-pointed Griſle is placed ſticking out, which they cal *Epiglottis*, which covers the paſſage of the Wind-pipe, while Meat or Drink ſlips over it.

the Cheſt.

Now the Cheſt, ſince it was to be partly a defence of the vital parts and partly the Inſtrument of Reſpiration; it was to be neither quite fleſhy nor quite boney. Therefore the Cheſt doth conſiſt of twelve pair of Ribs, which that they might come and go to dilate and contract the Breaſt, ſixty five Muſcles were made, thirty two whereof diſtend, and as many contract the Cheſt.

Its Ribs and Muſcles.

the Midrif

But becauſe there are no Ribs in the lower part of the Breaſt; that there might be in that place alſo a part that might be diſtended and contracted, and might likewiſe ſeparate the vital Organs from the lower Belly, a certain partition wall is interpoſed of a muſculous or fleſhy ſubſtance, which is called the Midrif, which when the Air is breathed forth

is raised up, but being loosened it is dilated, and depressed in Inspiration or drawing in of the Air, or fetching wind. And because through the *Diaphragma*, near the Back, the Gullet, the *Arteria magna*, and *Vena Cava* do pass, lest by the perpetual motion of the *Diaphragma* these parts should be straitened and agitated, the middle of the *Diaphragma* is Membranous, and contains no fleshy substance, that though the musculous part of the Diaphragme or Midrif is moved, yet that part may not be contracted.

Having done with the Vital Function, it follows in the next place, that we enquire by what means and with what Instruments the operations of the sensitive faculty are performed. And in the first place, that the Instrument of feeling which is the most common sense is a Membrane, hath been said already in Book 7. Chap. 6. But as to the Skin, 'tis true indeed that it is folded about the whol Body, not only that it may cloath the whol Body, and defend the other parts from external injuries, and that it may fasten and bind al the parts together; but also that it may be the Instrument of feeling, and may perceive external objects and injuries every way incident. And *Galen* rightly said 1. *de temper. cap. 9.* that the Skin, especially that in the hand, is the Rule of al sensible objects, and an Instrument of feeling properly fitted for so prudent a Creature as Man is. Yet nevertheless in that the Skin feels, it does it because it is Membranous, or receives fibres and little Nervous Membranes from the parts beneath it.

The Skin is not the adequate instrument of feeling.

The parts and use of the tongue

The Tongue is the Instrument of Tasting, whose flesh is spungy, rare and loose, covered by a most thin Membrane, common to the Mouth and Pallat, into which the Nerves of the third and fourth Conjugation are expanded. Now the Tongue hath three pair of Nerves; the former two are disseminated through the Coat thereof, and serve the Tasting Faculty: the third is spred into the Muscles of the Tongue for to move the same.

That the Organs of the Smel are the Mammillary Processes, was said before in Book 7. chap. 4.

The Organ of Hearing, its parts and use.

the implanted air

The adequate Organ of the Hearing is indeed the whol Ear. But what is the chief part in the Ear that contributes to Hearing, Authors are at great variance, while some say the implanted Air, others a certain Nerve is the immediate Instrument of Hearing. But if we shal diligently weigh the matter, these Opinions may be some waies reconciled, as was said *Lib. 7. cap. 3.* For it is altogether probable that a certain implanted Air or aery substance is required to cause the Sense of Hearing. For as to receive the visible Species the Organ of Sight is shining and lightsom; so also to receive sounds, 'tis credible that the Organ of Hearing is Aerial. But seeing the Organ of a Sense ought to be a part similar and animated, simple Air cannot be the Organ of Hearing; but it must be a certain Aery substance, bred of the most pure and Aery part of the Seed and maternal blood, such as may have affinity with the external Air, and may receive the sounds brought in. But whether this ingrafted Air be in the expanded Nerve, or in some Cavity, can hardly be determined; since Anatomy in this point affords little help, and after death we find nothing obvious to the sight. Whence also it is that that same other Question can hardly be resolved; Whether this Air be only an internal Medium, to receive and transmit sounds to the true Organ of Hearing, which is the widened end of the Auditory Nerve? or, Whether (which is the Opinion of *Capivaccius*) this Air it self seated in the expanded Nerve be the Organ of Hearing?

the external Ear

All the other parts of the Ear have each their use in Hearing. The external Ears by their sticking out do receive the sound, and cause it to rebound into the Auditory passage. Hence those that are crop-eared, or have their Earlaps cut off, they do not hear exactly, but perceive sounds like fluctuating Water.

the auditory passage or hole.

the Drum.

From the outward Ear or Earlap, the sound comes first into the Auditory hole, which is boney and covered with a thin Skin compact and smooth, and which sticks exceeding fast to the bone, fit to receive sounds. At the end of this hole or passage is a Membrane which they cal the Drum, made to this end, That the external Air might not slip into the Cavity of the Ear, and so disturb the Hearing.

Now this Membrane is exceeding dry that it may rightly receive sounds: for Instruments of Musick teach us, that the driest things are most apt to sound.

the three little bones of the Ear

No man can easily tel the use of the rest of the parts of the Ear, *viz.* The Cavities, the three little bones called the Mallet, the Anvil, the stirrup; since we have no such helps here as Looking-Glasses, Optical Glasses, and such like do afford us in our explication of the Instruments of sight.

the parts of the Eye, and their uses.

Somwhat we have spoken concerning the sight, Book 7. chap. 2. Its Instrument is the Eye; which hath many parts, each of which hath its peculiar use. The first is the *Cornea Tunica*, or Horny Coat of the Eye, which is transparent and void of al color, that the visible species

ſpecies may paſs there-through into the Eye, and that pure and uninfected with any ſtrange color. It is thicker than the Air, that the ſpecies comming out of the Air (a thinner Medium) into a thicker might be refracted.

the watry humor.

Betwixt the Horny Coat, and the Criſtalline Humor, the watry humor is placed in the middle, tranſparent and void of color for the Reaſon aforeſaid touching the *Cornea*. Now it is thinner than the *Cornea*, that here alſo may be a new refraction of Raies.

the Uvea tunica.

Next the watry humor comes the *Uvea Tunica* or Grape-skin Coat, which is furniſhed with ſuch a blackneſs as is not to be ſeen in al the body beſides, to the end the ſpecies might become more clear, and appear better in the Criſtalline humor. For weak Lights do more appear in an obſcure darkiſh place than in a lightſom. Alſo this Coat ſeems to have another End, *viz.* That over much light which might enter in at the Apple of the Eye, and offend the Eye and the ſight, might by this black Coat be intercepted.

the Apple of the Eye.

In the *Uvea* or the Grape-skin Coat, there is an hole which is called the Apple of the Eye, being the door as it were by which the viſible ſpecies do enter into the Eye. This hole (that the ſight may be more perfect and diſtinct) is much leſs than the compaſs of the *Cornea*: Yet in ſome it is larger, in others narrower; and thoſe that have it narrower do ſee more ſharply, thoſe that have it broad are weak-ſighted.

why it widens and narrows.

Now the *Pupilla* or Apple of the Eye is ſtraitened and widened, and in a light place appears narrower, in an obſcure place wider: For ſeeing two much light hurts the ſight, and a weak light is not ſufficient for ſight, and in an obſcure place the viſible object is not ſufficiently diſcerned; this Window (as it were) is made in the entrance of the Eye, which may be widened and narrowed, and by widening let in ſo much light in an obſcure place as may be ſufficient for ſight; and by narrowing exclude too much Light which may offend the ſight.

And in regard of this Conſtitution of the *Uvea Tunica*, there are three natural manners of ſight; one is moſt perfect, being conſtituted in an indiviſible point, and whereby we diſcern diſtinctly the ſmalleſt things: The other is perfect, when we ſee viſible objects at a juſt diſtance, and can diſtinguiſh them though we do not diſcern the ſmalleſt part of every of them: The third is imperfect and confuſed, whereby beſides things juſt againſt us (which we ſee perfectly) we do alſo confuſedly diſcern things on either ſide of us; and for this ſights ſake the Horny Coat is broader than the *Uvea* or Grape-skin Coat, to the intent that at one view we may behold divers things, though not al diſtinctly.

Now this is the Cauſe of this Difference. Seeing the comprehenſion of a viſible thing is made by a Pyramid; and the certification by its *Axis*; and only that perpendicular Line which is called the *Axis*, and which is not refracted, does effectually, plainly, and diſtinctly repreſent the thing; but other Raies, by how much they are neerer to, or further from it, by ſo much the ſtronger or weaker they are in repreſenting: hence doubtleſs it comes to paſs that when the Apple of the Eye is narrower, only the perpendicular in the Pyramid of ſight does enter, or with it the Raies which are neareſt the *Axis*; when the Apple is wider, more Raies (oblique and refracted) do enter with the perpendicular.

the Criſtalline Humor.

Next the *Uvea* is the Criſtalline Humor, which is not ſeated (as ſome imagine) in the Centre of the Eye, but in the fore part, and the Membrane compaſſing the ſame divides the Eye into two unequal parts, the foremoſt whereof is fourfold leſſer than the hindermoſt. And as to the uſe and office of the Criſtalline Humor, Authors do not a little vary: For ſome (and the greateſt part) do hold that this Humor is the chief Inſtrument of ſight, and that therein only the ſpecies are received and diſcerned: Others (ſeeing that the Glaſſie Humor is alſo tranſparent, and much greater than the Criſtalline, and placed behind the ſame) are of Opinion that the ſight is not terminated in the Criſtalline, but that the viſible ſpecies paſſing through the Criſtalline are received in the Glaſſie Humor, and being refracted are gathered into one point, and received by the Optick Nerve: which Opinion ſeems to be very probable. For ſeeing refraction is exceeding neceſſary to ſight; al this furniture of the Eye, and the variety of tranſparent parts therein was contrived, that divers refractions might be made. And hence alſo the Criſtalline Humor is more compact than the Watry, that a new refraction might be made therein.

whether it be the chief Inſtrument of ſight?

the Glaſſie Humor.

This Criſtalline Humor is ſeated in the fore part of the Glaſſie Humor, ſo called becauſe it reſembles melted Glaſs. Its ſubſtance is ſofter than the Criſtalline, and leſs fluid than the Watro. The Quantity hereof is ſo great, that it takes up almoſt three quarters of the Cavities of the Eyes. *Galen* and many others have hitherto thought, that this Humor was made to nouriſh the Criſtalline; but falſly: For what need was there of ſo great a quantity of the Glaſſie humor, if it were only to nouriſh the Criſtalline? alſo the Criſtalline Humor

mor

mor might be nouriſhed by a much readier way; nor needed ſo laborious a contrivance of the Glaſſie Humor, if it were made only for nouriſhment: nor is there any example in the whol Body of one part nouriſhing another, but they al draw their nouriſhment from the Veins, whether they be white or red. The Opinion therefore of others ſeems to be truer, who hold, That the Vitreous or Glaſſie Humor hath received this ſhape, place, and quantity, that therein the viſible Images or Raies being refracted out of the Criſtalline into the Glaſſie, which is leſs compact than the Criſtalline, might meet together in one point, and after that manner be offered to the ſight.

the Optick Nerves. The Optick Nerves ariſe from the hinder part of the Brain, and going forward a long way, they are at laſt inſerted into the Eyes. Theſe Nerves after they are gone a little from their original are joyned together, not by ſticking one to another, or croſſing one another, but by an abſolute Union; but ſoon after they are again ſeparated, and being divided, the right goes to the right Eye, the left to the left. And ſome wil have the reaſon to be, leſt viſible objects ſhould appear double becauſe there are two eyes. But ſeeing theſe Nerves are not joyned in their beginning, but on their way, it is more probable that the reaſon thereof is, That the Optick Spirit (when need is) might be ſent totally wel near into one Eye, that ſo the ſight may be ſtronger in one Eye; which comes to paſs when we ſhut one eye, that we may ſee a thing more accurately with the other.

But ſince Sight is made right forward, if the Eyes were immovable, we ſhould be able to ſee only ſuch things as are juſt againſt us. To the end therefore the Eye might ſee more things and that diſtinctly, it is furniſhed with Muſcles whereby it may be moved. And becauſe the Eye was not capable of al the differences of motions; ſuch as they want are ſupplied by the motion of the Head. But that one thing ſeen by the two Eyes may not appear double, both the Eyes are alwaies naturally moved to the ſame differences of poſition: and therefore the Nerves by which they are moved ariſe from the fore part of the Spinal Marrow, joyned together in one point as it were, that ſo they may agree together in every motion.

the Eye-lids: There are alſo beſides, certain outward parts ordained to aſſiſt the Sight, viz. Two Eye-lids, the upper and the lower: of which the upper is only movable; the uſe of which is to defend the Eyes from external injuries, as Air, Wind, Smoak, Duſt. Howbeit, ſome add alſo another uſe, viz. To purifie the Eyes: For ſince ſight requires a pure tranſparent body, and the Horny Coat is eaſily dimmed by reaſon of the moiſture which ſweats out of the Kernel, as alſo by the external Air: in the opening of the Eye they conceive the Eyelid wipes al foulneſs from the *Cornea Tunica*.

After the external Senſes come the internal, of which we have ſpoken, Book 7. chap. 7. The immediate Inſtrument by which, and in which they are exerciſed, is the Brain, which for the performance of theſe Functions is furniſhed with a peculiar ſubſtance, the like whereof is not to be found in the whol Body again.

the Brain: Now the Brain of a Man, the ſubſtance whereof is ſoft and white, in reſpect of the bulk of his body is exceeding great; becauſe Man-kind is more exerciſed in Animal actions than other living Creatures, and therefore needs great plenty of ſpirits, which cannot be bred but of much matter, and in a large place.

Its uſe. Now the Brain is made to perform the actions of the inner Senſes, and of the Rational Faculty, and to generate Animal Spirits, which are the immediate Inſtrument of theſe actions. And the Brain is moved by a Natural and peculiar motion for the better generation of Animal Spirits, and like the Heart in its Diaſtole it draws matter for the generation of ſpirits, and in its Syſtole it pours out the Spirits into the Organs of the Senſes.

Its parts. Now the Brain is divided into three parts. And the firſt is divided by the *Dura Mater* into the foremoſt and hindermoſt part: The foremoſt, in which the Spirits are chiefly generated, is called by the name of the whol *Cerebrum* or the Brain: the latter *Cerebellum*, the Brainlet or petty Brain. Moreover the Brain is again divided by the *Dura Mater* into two equal parts, the Right and the Left. The Brain hath alſo its Ventricles and other parts, which are all moſt diligently deſcribed by Anatomiſts, nor can they be here briefly recited, nor wel underſtood without ocular inſpection and figures.

In what part of the Brain the Animal functions are exerciſed. But let us here firſt enquire in what part of the Brain the Animal actions are performed. The vulgar Opinion is, That they are performed in the Ventricles: in which alſo they hold the Animal Spirits are generated of the Air drawn in and fetching breath, and carried into the Brain by the Organ of Smelling, and of vital Spirit ſent up from the Heart by the Carotick Arteries; and ſo they commonly hold the Ventricles of the Brain to be the Store-houſes as it were of the Spirits Animal. But late Anatomiſts having diligently weighed the Conforma-

tion

tion of the Brain, have left the said Opinion. For seeing nothing reaches into the Ventricles of the Brain, besides the Kernels, and that they have no passage save at the Tunnel and the kernel thereof (which by the consent of al receives flegm out of the Brain) it easily appears from hence, that those two remarkable Cavities (which are called Ventricles) were made to receive the excrements of the Brain: and that therefore they cannot also be the Shop and place of Animal Spirits. And therefore more likely it is, That the Animal Spirits are bred in the substance of the Brain it self, and that therein they are contained and perform their Functions.

whether the principal Faculties have different places in the Brain.

Moreover, it is also controverted; Whether al the Functions which belong to the Brain are performed in one part thereof? or whether they are exercised distinctly in distinct places? Some wil indeed have it, That the Faculties have several places, and they quarter the Fancy in the fore part of the Brain, Reason in the middle, Memory behind. And this makes them think so, because one action being hurt, the rest do remain sound. Others quarter al these actions together, seeing they are exercised about the same objects: Who indeed deny not that one action may be hurt, and the rest unhurt; but they say, this does not therefore happen because they are in several places, but because each action requires a peculiar dispostion in the Organ; whence it may happen, that one preternatural Disposition may hurt one action more than another; as for examples sake, moisture is more hurtful to the Memory than to the Fancy.

The common sense in the fore part.

The Memory, Fancy, & Reason not distinguished in their seats.

Now although it is hard to determine any thing in this Case, and we must needs confess as in most other things, so in this, as *Scaliger* hath it, *Exercitat.* 307. *Sect.* 21. We like the Wolf deluded by the Stork do lick the Glass, but cannot touch the Gruel: yet it seems most probable that the common sense is placed in the fore part of the Brain, seeing there al the external senses concur, whose Centre (as it were) the common sense is. But the other actions seem not to differ in their seats, seeing they are conversant about the same objects.

Ratiocination is performed without corporeal Organs.

There remains the most noble and proper action of a Man, Ratiocination, or Intellection, which is performed (doubtless) without the help of any Corporeal Organs. For the Mind does not understand by the Body or any part thereof, as the Medium wherewith. The Mind of Man indeed stands in need of a Phantasm (because the Soul while it is in the Body never understands without a Phantasm) but uses the same, not as an Organ, but as an Object: For if the Intellect were tied to any Organ, by help whereof it acted, it could not understand al things: but according to the determinate disposition thereof it should act and only understand some things: as the Sight by the Eye perceives only colored things, and nothing else.

the seat of the understanding.

And although after this manner we cannot assign any place to the Intellect: yet by accident and consequentially a certain seat is ascribed thereto, viz. That wherein the Imagination is made. Imagination and Ratiocination are joyned together in one Seat, and Reasoning is said to be performed in the Brain, rather than in the Foot or Liver; because in the Brain Phantasms are offered thereunto, which it contemplates, but not in the Foot or Liver.

the Instrument of Animal Motion.

After the knowing Faculty of the Soul, there remains yet Appetite and local motion, of which we spake in Book 7. chap. 8. where also it is said, That a Muscle is the Instrument of voluntary motion. And seeing there are four motions of Muscles, so that they are either contracted, or extended, or transferred, or remain bent, as *Galen* teaches in *Lib.* 1. *de motu muscul. cap.* 8. Yet Contraction, whereby a Muscle is drawn towards its head and proper Original, is the proper action thereof, by which the parts are turned any way as occasion requires. Now there is a great number of Muscles, by reason of the variety of the parts to be moved, and their sundry motions; and some move the Thighs, others the Arms and Hands, others the Back, Breast, Head, Jaws, and other Parts.

Its Fountain.

Motion flows from the same Principle that Sense does, viz. From the Brain; howbeit, from the hinder part thereof peculiarly termed the Brainlet or *Cerebellum*; and the Nerves arising therefrom are more solid, and are diffused through the substance of the Muscles.

the Legs.

And that the Body might be transferred from place to place, a Man hath Legs given him which are made of most strong Bones, to support the whol Body, and carry it from place to place; which that they might not be too heavy, are made hollow within.

the Feet.

And that a Man might stand firm and upright, and not totter as he goes, he hath Feet joyned to his Legs, which are hollow in the middle, so that a Man staies himself upon four props as it were: For when a Man moves forward, he sets the former part of his Feet more firmly to the ground, and bears most upon them.

their joynings.

And that the Feet may be variously moved, divers articulations are made. For we go into low places by bending our Knee; after lying or sitting we raise our selves up: which could

not be if our Leg and Thigh were not joynted. So we set our Foot more forward or backward, as the ground is up-hill or down-hill. Also the hollow part of the Foot when we go upon pointed things, or uneven bodies, laies hold on them as it were an hand; and after the same manner also we go up a ladder. And therefore the Foot (as a Hand) is divided into five Toes, which when we go do fasten upon the ground like hooks; and are also the cause that we can go upon rough and uneven places as wel as those that are plain and smooth. Now in the Toes of the Feet, the great Toe is not set against the other four as in the Hand, but they are al placed on a row after the same manner. For the Hand being the Organ of taking hold, and the Foot of walking; as in laying hold a great variety of motion, so in walking the firmness and security of support is requisite. Moreover, that the Feet might accommodate themselves to the variety of the ground whereon a Man goes; besides Toes they are compounded of divers Bones, in respect of which they are sometimes bended, sometimes extended.

the Hand. And because Man only of al living Creatures is endued with Reason, he also alone hath an Instrument of laying hold or taking up, which are the Hands, the Instruments of Instruments, by which only he can supply himself with whatever other Creatures naturally have more than he, as to defend or cloath themselves. Now two Hands are made, that if one wil not serve to hold a thing, both may. Again, they are variously distinguished, that we may take up great things and little things, and bodies of what figure soever. Likewise against the four Fingers the Thumb is placed opposite; because whatever we handle, either we enclose it circularly with our hand, or fasten our Fingers upon it on the opposite sides.

Speech & the usefulneß therof. Moreover, from the Motion of the Will Speech hath its original, wherewith we may conclude this our Epitomy: which as it is proper to man alone; so is it most profitable, and most highly necessary to preserve the Societies of Man-kind: For Speech was given us that we might demand of others such things as we wanted; and signifie what we had that we were willing to impart. And as *Scaliger* saies, in *Exercitat.* 256. from *Aristotle*: *Reason is the Hand of the Understanding; and Speech, of Reason; and the Hand, of Speech. For the Hands perform what they are commanded; the Commands obey Reason: Reason is the force of the Intellect.*

the remote Instruments of the voyce Now the Instruments of the Voyce and Speech, are some remote and common, others near and proper. The former are the Instruments of Respiration, the Lungs and the Chest, and those parts pertaining to these, the Midrif and the Intercostal Muscles; which do not frame the voyce, but afford Spirit and Air which are necessary to the formation thereof.

the near or immediate Instruments: Now the near are the Wezand, the Larynx, the Muscles which open and shut the Larynx, the recurrent Nerves, the *Epiglottis* and the Tongue. To which some others are subservient, as the Palat and the *Uvula*. Amongst the most immediate are the Larynx, and especially the *Epiglottis*, which is like the tongue of a pipe: For a pipe without a tongue is useless, nor can the voyce be framed unless the passage of the spirit or air be made narrow.

For Air and Spirit are required as matter to frame the Voyce: Instruments are necessary to drive it forth, which are the Lungs and Chest: there is need of an Instrument wherein it may be smitten, and wherein being smitten the Air may sound; which is the *Larynx*, whose orifice being straitened, and the Air smitten, the Voyce is caused. And because the Case so required that a man was not alwaies to speak, but when he lifted, the *Larynx* hath many Muscles, by which the chink of the *Larynx* may be widened and straitened as we please, and so sundry Voyces framed.

But because the Voyce of Man was to be articulate, to signifie the conceptions of his Mind, therefore his Tongue was framed with Muscles to move the same, wherewith being moved it variously opposes it self to the voyce issuing out of the *Larynx*, and so frames an articulate speech: to the formation whereof the Lips do also serve, which do themselves also oppose the voyce, and with their motion precede, accompany, or come after the motion of the Tongue, as the Nature of the Articulated Speech requires.

FINIS.

NATURAL PHILOSOPHICAL DISCOURSES.

The INTRODUCTION.

IT hath been both by me and others elſwhere at large declared, That there are two things which chiefly draw the minds of men from Truth, and hinder the growth of all Diſciplines; viz. A Servile kind of Credulity, and a raſh deſire of Innovation. How much hurt both of theſe have done to other Diſciplines, let thoſe ſpeak that are skilled in them. That I may ſpeak of Natural Philoſophy and Phyſick, which belong to my Profeſſion; it cannot be denied but that much hurt hath been done to both theſe, eſpecially to Natural Philoſophy, whiles ſome Men little regarding Reaſon and Experience, have ſolely adhered to the Authority of other Men; others out of a deſire of novelty have endeavored wholly to overthrow the foundations of ancient Diſcipline. From both theſe courſes I freely profeſs my ſelf to have been alwaies averſe: For neither would I be of the number of thoſe raſh Innovators, whether Paracelſians or Chymiſts, or how ever otherwiſe called, who endeavor wholly to baniſh from the Schools the ancient Philoſophy, which is come to us chiefly from the Writings of Ariſtotle: nor yet would I be reckoned amongſt them who are not aſhamed in this Age of ours publickly to profeſs, that they had rather err with Ariſtotle and Galen, than ſpeak the Truth with any later Author. The Innovators aforeſaid I paſs over at preſent. Touching theſe latter, I conceive Julius Cæſar Scaliger hath well written in Exercit. 306. That thoſe Wits are moſt unhappy which ſtifly maintain, That our Anceſtors knew al things. I do not verily envy Ariſtotle thoſe praiſes wherewith the ſame Scaliger every where adorns him. Let us grant that Ariſtotle is a man that hath deſerved more than all mortal men beſides, of all the parts of Humane Knowledg; that he is the Father and Captain of our Wiſdom; that he is the chief Dictator of Learning, the Emperor of Philoſophers; that he is the Eagle of the Philoſophical Kingdom of Wiſdom, and Literary praiſe; that he is the Hercules, the Prince, the Tribunal of Truth; that he is the god of Philoſophers; and in a word, greater than all praiſe, and above all Calumny: yet neither he nor any mortal Man can be made the Rule of Truth. Let it be counted a comely and a decent thing to cite the Teſtimonies of Ariſtotle as of a prime Philoſopher for his Opinion, and to produce as many of them as may be: but if weighty reaſons be not added, a mind deſirous of the Truth will not be contented with theſe alone. Their Courſe therefore is by no means approvable, who taking no care for reaſons, contend only with Authorities. Yet this is a fault common enough. For if we look into the Writings of ſome Men we ſee nothing brought to prove their Matter, but the Authorities of Hippocrates, Ariſtotle, and Galen, and oftentimes many interpretations are alleadged touching the ſence of ſome one place, and all thoſe rejected, and at laſt another ſubſtituted, perhaps no better than the former, and ſo in diſputing thereabouts pro and con, ſo many Pages are taken up, that he muſt have abundance of leiſure that would read them all. And which is a ridiculous thing, the contention is not ſo much about the mind of the

Author speaking in his own Language, as the Interpretation of a barbarous and faulty translation, which is obtruded for the mind of the Author; and so they play at Blind-mans Buff.

So much reverence ought indeed to be afforded Aristotle, that if any thing seems by him inconveniently expressed, it be softened with a fit Interpretation. But if the matter be plain, (only some opinion of Aristotle doth not agree with the truth)'tis vain to labor to fix another sence upon Aristotle. And that which is the top of all the mischief, you shal find such opinions given out every where for Aristotelean, which are no where extant in Aristotle, being the Inventions of School-men, whose custom hath been to delight themselves in disputing al things pro and con.

Which thing, as I said, doth not a little hinder the progress of al disciplne; whiles both our time is lavishly wasted, and consumed without profit, of which we ought to be sparing Stewards, since life is short and Art is long; and we wander from the way of finding the truth. For there are two Principles only of finding out all truth, and Touch-stones of all opinions, Reason and Experience. He that follows these two doth not easily err: but they who neglecting these do fly to that external Argument, viz. Authority, and like Slaves swear to the sayings of one man, and of a Man make a kind of God, who cannot be deceived; they easily slip into sundry Errors. Hence (to speak nothing of Physick or other parts of Philosphy, but to keep me to natural Philosophy, for whose sake I speak all this) amongst the Expounders of Aristotle (whom all the Philosophers wel nigh of all Nations for some ages last past have believed so to have perfected this part of Philosophy, that there needs no further labor but to understand his writings) so many dissentions and so many indissoluble objections, to and fro, have arisen, which in so many ages of years have not been ended, but that dayly they have divided into many sects, while disputing upon the suppositions of several sects, one man will maintain one way, another man another; this man being for Averrhoes, a second for Thomas Aquinas, a third for Scotus, a fourth for another; that you cannot tel whom to give credit to. And that is true of Euripides, One man sees not all things. And no man hath ever been found, that hath not erred and mistaken, or as Galen hath it: It is hard for him that is a Man not to offend in many things, viz. being quite ignorant of some, judging amiss of others, and negligently letting down other things in writing. And therefore when free and excellent wits, and prudent Men had observed, that the Authorities of the Ancients had hitherto more bindered than furthered the Advancement of Learning; and saw that thereby a Bridle was cast upon the Understanding of Man, and upon many excellent wits; they endeavored to cast off this yoke of Bondage, and to seek the knowledg of things from the things themselves.

Yet they themselves also who have not followed only Authorities but weighed the Things themselves have not al happily touched the white of Truth. For seeing, as hath been said, Reason and Experience is the Rule of Truth in matters of Nature: Experience must of necessity precede, and when a thing is so found out, Reason is to prove the same: wherin nevertheless many offend; for seeing many neglect Experience, and rely only upon Reasons, & give too much credit to their speculations, they must of necessity be very often deceived. Of which thing we have every where remarkable Documents; some of old trusting to certain sleight reasons denied there were Antipodes; amongst whom was Lactantius, who largely inveighs against those Philosophers who held there were Antipodes, in Divin. Institut. Lib. 3. cap. 24. & counts those men fools who beleeved there were such Antipodes who hung by their Legs, and whose Feet were higher than their Heads: and cals it folly & vanity to hold there were Men in the world who went with their Feet just against ours. And Augustine de Civitate Dei Lib. 16. Cap. 9. counts it fabulous to beleeve, that there were men on the other side of the Earth, who went with their Feet against ours. Yea and Aventinus relates, that there was one Vigilius a learned Man, who could not avoid the thunder-bolt of Excommunication, for holding that Men lived about the Globe of the Earth and went with their Feet one against another. For Pope Zachary writ to Boniface, to drive Vigilius from the Church as an Heretick, and to deprive him of his Priesthood, unless he would abandon his perverse Doctrine. So, in the foregoing ages some endeavored by sleight reasons to perswade that the torrid Zone was not inhabited; both which Experience and late Navigations have taught to be false. So some idle Monks and others of the last ages preceding, taught many things, trusting to their speculations, concerning the Body of Man, which Experience and Anatomy do shew to be false. Jacobus Zabarella a most learned Interpreter of Aristotle acknowledged this Error, who in Lib. 2. de propos. necess. cap. 17. thus writes:

All

All these things are so true, that all men ought to know them by Inspection of the things themselves, if in these daies we had Philosophers, who Philosophied by searching diligently into the Natures of things; and did not only addict themselves to the words of *Aristotle*, and those many times misunderstood, to which they are wont to accommodate the things themselves; seeking nothing else but what *Aristotle* saith, and taking their Arguments for the knowledg and proof of all things, only from his words. *The Premises considered, not out of any desire to inveigh against and carp at* Aristotle *(whom I reverence as much as any man can) or any other Persons, but only out of desire to find out the Truth, I began more diligently to examin certain things referring to some Controverted Heads of natural Philosophy. For although somwhat above thirty yeers ago, I collected a certain Epitomy of natural Philosophy, and afterwards published the same: yet the reading of other Authors and especially of Physitians (who have handled natural Philosophy more diligently than other men, and are therefore called Physitians, that is to say, Naturalists) the Consideration of natural things, and exercise of chymical Operations, and in a word, Experience hath taught me many things; so that to use the words of the Comick Poet,* Such things as I thought I knew, I am ignorant of, and such things as I had an high conceit of, Experience teaches me to reject. *I conceive indeed, that the most things I wrote in that smal Epitomy are agreeable to Nature; but yet I suppose there are some things which may be more rightly, or cleerly expressed. Whereof, I think I am not to be blamed for admonishing my Reader; since very many most learned men have done the same before me, which therefore I thought fit briefly to comprize and joyn as an auxiliary Appendix to the foresaid Epitomy, and those things especially, which concern the Principles and Foundations of natural Philosophy, not only general, but special also. For the chief cause why natural Philosophy is so little improved, I conceive to be, that in the former Ages those who accounted themselves the most acute, consumed the greatest part of their life in those general Questions, concerning the first Matter, Form, Privation, Motion, and such like, and wasted the time in repeating those Disputations over and over again, after a most tedious manner; but things particular or the sorts of natural things (out of the Observation whereof they ought nevertheless to have constituted their principles) they never medled withall to any purpose. And hence it came to pass that so many Wainloads of Commentaries arose upon* Aristotle's *books of general natural Philosophy, filled for the most part with Questions rather Metaphysical than Natural, and many times with vain speculations. But few were found that would read or Comment upon* Aristotle's *books of Meteors, of the History of living things, of the Parts of living things, of the Generation of living things, or of Plants; scarce so many in number,*

As Gates of *Thebes*, or Heads of fruitful *Nile*.

And although I know, that by these my endeavors I shal lay my self open to the Calumnies of many, and that I shal be counted an Innovator and an Inventer of Paradoxes: yet I have not thought fit therefore to forsake the study of truth. For Aristotle *wel saies in* 1. Ethicorum cap. 4. It is a good thing, yea and our Duty, for maintainance of Truth, to change and abolish our former Opinions and Tenets. *Which things he taught not only by word and writing, but by Deed and Action. For although* Aristotle *heard* Plato *teach twenty yeers together; yet he suffered not himself to be brought into bondage by the Authority of his Master, but he freely enquired into the Tenets of him and al other Philosophers before him, opposed them at pleasure and rejected them, substituting in their rooms such things as he thought most probable. And therefore we that follow, do ow no more Reverence to* Aristotle *than he did to his Predecessors; but we ought so to follow* Aristotle, *as that we do not love him better than the Truth.* Galen *boasts of himself that he was alwaies of a free spirit, and preferred Truth before the Doctrine of* Hippocrates, Plato, Aristotle, *and the wits of other Men. And are we all born Servants and Slaves to other Mens opinions? 'Tis excellently spoke by* Seneca: They have done many things who are gone before us, but they have not done all. There remains yet much work behind, and much wil remain; nor shal any man born a thousand Ages since want occasion to add somwhat. *And above all things this shall be my endeavor, that all my Discourses of Natural Philosophy may tend to the honor and Glory of the most good and great God. Concerning whom I am admonished by St.* Paul, Rom. 2. *verse* 20. His invisible things are seen by the Creation of the World, being understood by the things which are made, viz. his Eternal Power and God-head, to the end they might be without excuse. And *Mercurius Trismegistus*: Man is made a Spectator of the works of God, and he hath wondred at them and acknowledged the Creator. *And again in his Book* da Pietate & Philosophia: there

can be no more true Godlineſs than to Underſtand the things that are, and glorifie the Creator for them: *and preſently after*; Be Godly O Son; he that is Godly is a Philoſopher in the higheſt degree. For it is impoſſible to be eminently Godly without Philoſophy. But he that learns what things there are in the World, how diſpoſed and by whom, and for whoſe ſake, he wil give thanks to the Work-Maſter as to a good Father, tender Nurſe, and faithful Steward: and he that gives thanks is Godly. And he that is Godly wil know where the Truth is, and what it is; and the more he knows the more Godly he wil be; *viz. With ſuch a kind of Godlineſs as may be attained from the Principles of Natural Philoſophy, Theoretical and Practical. For who can chooſe but be Godly who truly diſcerns the immenſe Omnipotency, Goodneſs, and Wiſdom of God? For he is (as* Auſtin *ſaies) without place, and in every place; inviſible, and beholding all things; immutable and changing all things; alwaies working, and evermore quiet; he fills all things and is not ſhut up; minds all things, and is not troubled; is great without quantity, and therefore infinite; good without quality, and therefore good in the higheſt degree.*

THE FIRST DISCOURSE.

Of the Principles of Natural Things.

Chap. 1. *That it is neceſſary for a Natural Philoſopher to know the Creation of the World.*

Two manner of Principles of Natural things.

HE that would treat of Natural Things muſt make it his chiefeſt care to handle the Principles of Nature; the Doctrine whereof being not rightly laid down, al things built thereupon muſt needs fal to ground. Now two kinds of Principles of Natural things muſt neceſſarily be conſidered and underſtood, *viz.* Thoſe of their Original and firſt Creation, and thoſe of their duration or continuance. The firſt kind of Principles muſt by any means be diligently conſidered, and he that enquires into the firſt Principles muſt neceſſarily enquire into God himſelf. For he is the Firſt of all, and the Principle of al other Principles, having created al things Natural, and preſerving them when created; ſo that they retain to this very day that Eſſence which he gave them at their firſt Creation. And herein chiefly moſt of al the Heathen Philoſophers are deficient or very barren, and no mention at al (or but on the by) of God the firſt Author of Nature; and they ſo deſcribe the whol Courſe of Nature as if al were performed without a firſt Cauſe, only by the action of ſecond Cauſes, and indeed contrary Principles. *Socrates* raiſed his mind a little higher, when a little before his death, as *Plato* relates in his *Phædo*, having heard out of a certain Book of *Anaxagoras*, that there was a certain Mind which diſpoſes and rules al things, and is the Cauſe of all; he ſaid he was much delighted with this Cauſe; adding moreover, that thoſe men exceedingly erred who reſted in the ſecond Cauſes and neglected the firſt. And he cals the Mind, or God, the Cauſe indeed; as without which the other Cauſes termed ſecond Cauſes, are no Cauſes.

The Natural Philoſopher muſt know God to be the firſt Principle of all things:

the ſecond Cauſes:

As to what concerns theſe ſecond Cauſes, or the Continuation and Conſervation of things created; ſince ſome Natural Things keep their Eſſence entire, ſuch as they were created at the beginning of the World without any mutation; but other things are preſerved only in their

their kinds, their particulars being subject to continual Corruption and Generation; we must also consider the latter kind of Principles, viz. The Principles of corruption and Generation.

As to the first kind of Principle, since al things (as al in their Wits grant) are governed by the Providence of God alone; they must also of necessity depend on him as their efficient; and seeing before any Natural things were made, there could be nothing but the most good and great God, we must needs hold that he is the first Author of all Natural things; who, when there was nothing besides himself, and there was no matter for him to work upon, by his Infinite Goodness, Wisdom, and Power, he commanded those things that were not, to be made. Which thing also the more sound Philosophers granted after their manner, although they did not cleerly enough explain the matter it self. Not to speak of others, *Plato* truly approved of the Original of the World, although he with-held his assent from some things concerning the same. For he constantly affirms, That the World did not proceed from Nature, nor from Fortune, nor was made by Hap-hazard, but that it flowed from the Wil of God, not bound by any necessity. But whether from Eternity a certain Matter did proceed from God, and was al at once formed into this variety of things, or being at first unformed, after an infinite tract of Time, he did adorn it with so many Forms, or, which is the only thing that remains, he performed both in Time, he neither saies nor denies, and reasons in such a manner of the Original of the World, that which way soever you turn and wind al that Disputation which he makes thereof in his *Timæus*, it wil seem to favor al these Opinions. Which also may be said of the Opinions of other Philosophers before *Plato*. And hence it came to pass that the Philosophers which came after *Plato* were of sundry Opinions hereabout. *Aristotle* truly, though he acknowledg God to be the Maker of the World, when in the 2. *de Generat. & Corrupt. cap.* 10. *text.* 19. he writes; *God hath filled the Universe:* and in the 30. Section of his Problems, the 5. Problem; *God hath given us two Instruments in our selves, by help of which we might make use of external Instruments:* yet he endeavors confidently and openly by divers Reasons to deny, That God made the World new and in time; and to overthrow the Opinions of the Ancients touching the Original of the World. And therefore though he acknowledg God the Author of the World, yet herein learned men conceive he contradicts himself, since Eternity is a duration proper to God alone, nor can a Creature be co-eternal with the Creator; nor can there be two Infinites, nor wil right Reason allow us to make the World equal to God. And hence a grievous controversie hath been raised amongst the Peripateticks concerning the mind of *Aristotle* in this point, nor have they as yet wel decided the Controversie. For there are two things principally which al Philosophers in a manner cannot understand, viz. How the World could be made of nothing, and how it could be made in time; for when they saw other Artificers make their Works by mixing some things, and taking away other things; they imagined that God also had thus made the World. And therefore though they granted God to be the Author of the World; yet they held there were before the Original of the World certain bodies, either floating up and down in the immense Space, or lying hid in a certain confused Chaos and Medley. But they were both ignorant who made those bodies: and if they grant God to be infinite, they might believe he could produce somthing even of nothing; especially since there was nothing before any matter imaginable, but he.

The World created by God:

The World created of nothing

Another thing which offends them is, That they think it absurd that God should be so long a time idle before the Worlds Creation, and at last set himself upon a new work. But since in Eternity there is neither fore nor after, it could not be made before it was made, unless it should be made from Eternity. But to be made, and to be made from Eternity imply a contradiction. And if you ask why the World was made five thousand years ago, and not twenty thousand years ago? I ask again, Supposing it was created twenty thousand years ago, why not an hundred thousand years ago? and if an hundred thousand years ago, why not an hundred thousand thousand years, and so stil forwards, unless it had been made from Eternity, which cannot be? For Eternity is a point wherein there is no going before or coming after. But the Philosophers could not by the reasons meerly of Nature and their own understandings, come to know the power of the most good and great God, who acts above the powers of Nature. But we may know these things very wel out of the holy Scriptures, the use whereof is by the goodness of God afforded unto us; and therefore those things in which the Philosophers are defective must be supplied from them. For though the holy Scriptures are not written to interpret the things of Nature: yet inasmuch as those things which are written by *Moses* touching the Creation of the World, were dictated by Inspiration of the holy Ghost; we must needs think that al those things which we read in the History of the

the World was made in time:

the use of the holy Scriptures in natural Philosophy

the Creation are most true: and that it is impious to suppose any thing there said to swerve an hairs breadth from the Truth. And suppose (which I do not now dispute) that every where in holy Scripture we meet with some things which are spoke according to the Opinion of Men, and either Tropically or otherwise Figuratively according to the Capacity of the common people: yet that cannot any waies be said of the Creation of the World, because God would have that made known to Men only as it is comprehended in this Writing of *Moses*, even to the end of the World. And although the primary scope of the holy Scripture is to propound the means to eternal Salvation: yet the History of the Creation of the World is not to be excluded from those means, as the Apostle teaches in the *Romans*, chap. 1. verse 20. seeing withal there are therein such Revelations of Natural things, as to which no sharpness of Humane Wit could ever be able to attain. An Example whereof the Creation of the World, and *Aristotle* himself, do afford. For let us suppose as *Julius Cæsar Scaliger* conceits, that Nature hath in *Aristotle* made ostentation of al the Wit Humane Kind is capable of; yet he could never attain to know the Creation of the World, as the most learned Peripatetick confess. And therefore to depart from the evident sence of Scripture and to assent to Pagans, is neither Lawful nor Godly. And although it be indifferent as to Eternal Life, what Opinion any Man holds in the things of Nature, and in this darkness of the minds of mortal men it can be no prejudice to a mans attainment of Eternal Life, if out of weakness of Understanding he err in this point: yet if any man does wittingly contradict the holy Scriptures, and esteems the Authority of an Heathen more than the holy Writ, I conceive that questionless he sins very grievously. Truly *Galen* cannot (nor ought he by any Christian Philosopher or Physitian) be excused who in his second Book of the difference of Pulses, chap. 4. carps at the School of *Moses* and of Christ, as delivering Laws not founded upon any Demonstration. And in his Book 11. *de usu partium*, where he disputes of the Hairs of the Eye-brows, he derides *Moses*, as if God the Creator had commanded these Hairs alone to keep alwaies an even size, and that they as fearing the power of the prescriber, or reverencing God himself that gave them that command, or being perswaded that it was best to do thus, they did as they were commanded. And afterwards he reprehends *Moses* for supposing that God could make all things, although he would make an Horse or an Ox of ashes; and he holds and determines that God himself never undertakes any thing which Nature cannot effect, and affirms that the Hairs of the Eyelids would not have been such as they are if they had sprung out of the soft skin, though God should have willed and commanded the same a thousand times. Well therefore did that same famous Philosopher and Physitian *Franciscus Vallesius*, who in the Proeme of his Book *de sacra Philosophia*, is not ashamed ingenuously to confess, That when he was a yong man he wrote Matters Philosophical (viz. When he commented upon the Physicks of *Aristotle*) according to Opinion (that is the Mind of *Aristotle* and his Interpreters) but that he writes these things according to the Truth, that is to say, agreeable to the History of the Creation in holy Scripture, seeing before he could have no certainty concerning the Principles of Natural things before he knew them by reading the holy Scripture, to the reading whereof he had consecrated his old Age. And I have been long of the mind, That he who not knowing, or neglecting the Creation of the World, shal undertake a Dispute of the things of Nature, he shal err in many things; yea, and that many upon that occasion have fallen into most grievous Errors.

Things to be observed in the explication of the History of the World

Now *Moses* hath described the History of the Creation in the first Chapter of *Genesis*; the Interpretation whereof to set down in this place, I count not worth the while; since there are many large Commentaries extant thereupon, and amongst the rest that of *Franciscus Vallesius*, which though it be short is none of the worst. Only I shal advise you of one thing; That there are many who affix a wrong Interpretation upon the Text of *Moses*, whiles they endeavor to expound *Moses*, not by *Moses*, but from the Writings of Heathen, an unhappy and intollerable design. For it is certain amongst al Christians, that al things delivered in the holy Scriptures are true, and those delivered by *Moses* (being plainly Historical) are to be understood according to the proper and genuine sense of the words, as they are commonly understood in the Holy Scriptures; and not to be explained according to pre-conceived Opinions sucked in by reading Heathenish Authors: nor is the holy Scripture to be wrested to such Opinions. And therefore *Augustine* gives a good warning in the beginning of his second Book upon *Genesis*, that we take heed lest we contend, not for the sence of the holy Scripture, but for our own Opinion, so that we would make that to be the Opinion of the Scripture which is our Opinion; whereas we should rather be willing to make that our Opinion which is found to be the sence of the Scripture. The History (truly)

of

of the Creation is not repugnant to Nature, but it is many times oppoſite to the falſe Conceptions which Men have of Nature; concerning which the ſame *Auguſtine* in his ſeventh Epiſtle to *Marcellus* thus writes: If a reaſon be given contrary to the Authority of the holy Scriptures, be it never ſo acute, yet does it deceive by an appearance or ſimilitude of Truth. For it cannot be true. Again, if a man does oppoſe the Authority (as it were) of the holy Scriptures againſt moſt manifeſt and certain Reaſon, he that does ſo underſtands not himſelf, and he does not object the ſence of thoſe Scriptures which he cannot dive into, but his own ſence againſt the Truth; nor does he oppoſe what is in them, but what he finds in himſelf in their ſtead as it were. And therefore although it ſeems hard to many to abandon ſome Hypotheſes of Natural Philoſophers, becauſe they agree not with the Hiſtory of the Creation of the World: yet is it altogether neceſſary ſo to do, ſeeing there are ſome things in *Ariſtotle* contrary to the Hiſtory of the Creation of the World. For as *Benedictus Pererius* (an excellent Ariſtotelean) hath ingenuouſly written, *de Com. Rerum Nat. princip. Lib. 5 cap. 7.* nothing can be found out or imagined which is more contrary to the Doctrine of *Ariſtotle*, and which does more vehemently break al his Joynts and Nerves, than the Creation of the World. And a little before; When the Peripateticks perceived that a Creation being allowed, moſt grievous inconveniences would follow againſt their matter, they could by no means be induced to grant the ſame. And he who wil examine ſome Teners of *Ariſtotle* ſhal eaſily perceive that *Pererius* was not miſtaken when he ſo thought and wrote. And he ſhal ſee the ſame (not to ſpeak now of the Eternity of Motion, and of the World) who wil but conſider the Doctrine of *Ariſtotle* concerning the Principles of things Natural. But it is not my purpoſe to produce al the Teners of *Ariſtotle* which may be called into queſtion, nor is it my deſign to ſubvert the Natural Philoſophy of *Ariſtotle*, but rather to ſhew which way the ſame may be perfected. And therefore I ſhal only hint a few things concerning the ſame.

Chap. 2. *Whether the Principles of Natural things are contrary.*

Whether the Principles are contrary?

ARiſtotle in the firſt of his Phyſicks, chap. 6. preſuppoſes this as a thing granted by all Men, That the Principles of Natural things ought to be contraries. Now he was perſwaded to hold this Opinion, either becauſe he beleeved that the generation of al Natural things was performed by the action of Contraries, and that when one contrary overcomes another, this thing periſhes, and another is generated; or becauſe he would inſiſt in that Method by him pointed out in *Lib. 1. Phyſicor.* and proceed from things moſt known to us, to ſearch out the Natures of things. But ſome Expoſitors of *Ariſtotle* have long ſince told us that this propoſition is not univerſal, nor hath place in al Phyſical things. For ſince the World hath two ſorts of Parts, ſome that have remained incorruptible and unchangable to this very day, viz. The Heaven and the Stars; ſome corruptible, whoſe Individuals are generated and corrupted, yet the kind is preſerved by a continual ſucceſſion of the ſaid Individuals; it eaſily appears, how thoſe principles belong to the Heaven and Stars. As for Matter, it belongs indeed to the Heaven, but not by a definite contrariety, but only affording Magnitude. For (which *Ariſtotle* wil not deny) the end of matter is to be the Receptacle of Forms, both ſubſtantial and accidental; and therefore in 2. *Phyſ. cap.* 8. *text.* 81. he terms the Form the End of the Matter; and the ſame Matter gives corpulency and an indeterminate magnitude to things, and hath an aptitude to receive Forms, and a determinate figure, and of it ſelf is no waies the Cauſe of Generation and corruption, but receives thoſe effects from ſome Agent, or as *Scaliger* writes in *Exercitat. 61. Sect. 1. Matter was not given primarily and of it ſelf, for to cauſe a tranſmutation to generation; ſo that where ever it is, there alſo Generation ſhould be; but to be the ſubject of the form of Corporiety in a ſubſtance, and to receive Quantity and Figure: Quantity in regard of change of place; Figure, becauſe every body muſt and ought to be finite.* And a little after, *For theſe Cauſes Matter (by a primary Councel of God) was created; but ſecondarily, and as to a leſs noble end, for Generation.* And therefore although Matter belongs to al Natural things; yet, that the Principles of Natural things ſhould be contrary does not belong to al; ſince in the Heavens and Stars (according to the Opinion of *Ariſtotle* himſelf) there is no Generation, and no contrariety, which might be the cauſe of Generation and Corruption. And therefore Principles with a definite and determinate Contrariety are not the moſt general, but do belong only to bodies ſubject to Generation and Corruption.

the End and uſe of Matter.

Moreover,

Moreover, they do not belong to al corruptible and mutable things neither, but to such alone as are made by the action of contraries, and not to such as are made of seed. And touching this very Contrariety of Principles, and concerning them how they are contrary, the Peripateticks themselves are at great variance; of which see their Commentaries. Howbeit, the most of them do not place a true Contrariety in the first Principles, but such an opposition as is between the Habit and Privation, as *Zabarella* writes in his first Book *de materia prima, cap.* 2. and thus of an Egg which is no Chick, a Chick; and of Wood which is no Statue, a Statue; and of Potters Clay a Pot they say is made, and that Generation is a passage from a Privative to a Positive Essence.

But in good deed, thus going to work they have not sufficiently explained the Doctrine of the Generation of things, nor have they sufficiently laid down the Causes of Generation. For in the first place those examples which they bring of Artificial things, as when a stool or statue is made of Wood, a Pot of Potters Clay, a Globe of Wax, and such like, are all to be rejected: seeing they are not produced by operation Natural, but are the works of Art. Moreover, although we should admit a Contrariety in things Natural, in regard of their forms, by which many actions and Sympathies and Antipathies are caused, as Water is contrary to Fire, and Plants are killed by the Cold; yet from that very Contrariety a Cause of the Generation of al things cannot be rendred, nor is that Generation which is primarily intended, accomplished by the Action of Contraries; and therefore it cannot be granted that contrary Principles must be constituted for every Generation. For that a Sheep produces a Sheep, a Plum produces a Plum, does not proceed from the Action of Contraries.

And therefore although the Expositors of *Aristotle* having canvassed the matter to and fro concerning the Contrariety of Principles, do at last conclude, That one Contrary is not made of another, as of the term from whence, but that one Contrary is made after another; as for example, Cold after Hot; yet that term infers no causality, and affords nothing to the production of the thing, and therefore cannot be called a contrary Principle.

Chap. 3. *Of the Form.*

the Form the principal Cause of Generation.

And therefore besides the Matter, our great Care must be to find out a Principle which is the efficient Cause and principal Agent in the Generation of al things. Verily (that I may not seem injurious to *Aristotle*) I must needs confess, that he in *Lib.* 4. *de Ort. & Interit. cap.* 9. *text.* 53. *&c.* as also in the end of the 4. of *Meteors*, reprehends the Ancients, because they did teach the Generation of things to be caused by the first Qualities, too instrumentally, omitting the Cause taken from the Form, and doing just as if a man should attribute to the Saw, Hatchet, and such like Instruments, the things made by them. But I could wish that in the beginning of his Physicks he had made larger mention of that Cause, or at least that his Expositors had from other places of his Works explained what *Aristotle* taught in his Acroamaticks concerning the Principles of Natural things. For so doubtless they would have enquired thereinto, and would not have been so content with the action of contrary Principles, and taught that the Generations of things were so instrumentally performed by them. Yea, and it were to be wished that *Aristotle* himself had been more sollicitous about that Cause, or had more largely explained the same, and not extended too far the action of the first Qualities. At the end indeed of the 4. of his Meteors he plainly laies open his mind; where he attributes the Generation of similar parts in Animals to the action of the first Qualities, but the Generation of the dissimilar parts alone he attributes to a superior Agent, while he thus writes: Such parts happen to be made by Heat and Cold and their motions; being compacted by the power of Heat and Cold. Now I mean those parts which are similar, as Flesh, Bones, Hairs, Nerves, and al that are like to these. For they are al distinguished by those differences which we mentioned before, viz. Tension, Drawing, Comminution, Hardness, Softness, and others of the same kind. For such parts I say are made by heat and cold and mixt motions. But no man can imagine that the dissimilar parts, as the Head, or Hand, or Foot, are constituted of them: but as the motion of Cold and Heat is the Cause why Brass or Silver are made, but not of the making of a Saw, Glass-bottle, or Box; but of these Art, of the other Nature, or some other Cause: and so it will be thought to be the cause that those things are made. But whether this Doctrine of *Aristotle* be perfectly currant, I leave to the Reader to judg. *Galen* (truly) and other Physi-

tians,

rians ascribe not only the Formation of the dissimilar parts to the Soul; but also they attribute thereto a blood-making, flesh-making, bone-making, nerve-making Faculty; and doubtless they are therein in the right. And who can beleeve that Gold, Silver, Iron, are generated principally and solely by Heat and Cold; and that the efficiency of the Form is not added. Moreover, neither hath he sufficiently declared what that specifick cause is in the Generation of things, but neglecting the same he often runs to the Universal Cause. For in his Book *de Generat. & Corrup. cap.* 10. and the following Chapters, he makes no mention thereof, but after he hath rejected the Opinions of the Ancients, and would produce his own, he flies to the Motion of the Heaven; and after he hath taught that the Motion of Heaven is perpetual, thence he concludes by way of Consequence, That rather that which is should be the Cause of that which is not, than that which is not the Cause of that which is; and that that which alwaies is, should make and produce that which is not and is generated. But at the beginning of the World, neither did the motion of Heaven make things Sublunary, nor now being only an universal Cause does it produce the sorts of things. For God in the first Creation gave to things their Forms, by which the Order of Generation is continued and perfected; and these Forms are justly held to be the Agent Principle, and as the Expositors of *Aristotle* themselves do hold, have a power to multiply themselves; and all the Generation of Natural things depends upon the multiplication and propagation of Souls, by reason of the Faculty which by the Almighty power of God was put into them at the first Creation, when God said, *Gen.* 1. 11. *Let the Earth bring forth Grass, the Herb yielding seed, and the Fruit-tree yielding Fruit after his kind, whose seed is in it self upon the Earth: and it was so. And the Earth brought forth Grass, and the Herb yielding seed after his kind, and the Tree yielding Fruit, whose seed was in it self, after its kind.* And in verse 22. he said to the Fishes and Birds; *Encrease and multiply, and fill the Waters in the Seas, and let Fowl multiply in the Earth. And God made the Beast of the Earth after his kind, and every thing that creepeth on the Earth after his kind: and God saw that it was good.* And to Man-kind he said, verse 28. *Encrease and multiply, and fill the Earth.* Also in verse 29. *Behold I have given you every Herb bearing seed, which is upon the face of all the Earth, and every Tree in which is the fruit of a Tree yielding seed.* But as to the manner of Generation; The generation of Plants and Animals does sufficiently declare, that their Generation is not caused by the action of contraries one upon another, but by the communication of Souls, or by Seed which perfects the Fabrick of its own body, not primarily by the action of contraries, but by attraction of things friendly and of kin, and the expulsion of things having Enmity. For, that the body of some Plant or Animal is made, does not come to pass by the only concourse and fighting of the Elements. For except, as *J. Cæsar Scaliger*, in *Exercit.* 307. *Sect.* 20. rightly teaches, *Those four Elements have a Governor, they will both toss and be tossed rashly without manner or measure. For what is that which mixes just so much Earth, and so much of the other Elements? But there ought to be in every motion one first mover. For they cannot move themselves to the Production of any work; but in Compounds they are moved by the more excellent Form to Generation, and in imperfect mixt Bodies by an external Principle they are moved to a mutual connexion.* For instance, when the Seeds of Plants are cast into the ground, the Elements do not then begin to fight that they may make the Body of a Plant, but each particular seed draws out of the Earth such nourishment as is to its own Nature agreeable, some that which is harsh, others that which is bitter, sweet, salt, as *Hippocrates* writes in his Book *de Natura Humana*: whence the whol Plant is formed, nourished, and attains to its growth.

The first Original of Forms.

Yea, and even *Aristotle* himself when he treats of Generation, cannot rest in the first Qualities, but is compelled to ad an higher Agent, viz. The Soul, even in the Generation of the similar parts, whiles in 2. *de Generat. Animal. cap.* 1. he writes: *Even as we do not say that an Hatchet or other Instrument is made by the fire alone: So neither the Foot nor the Hand, no nor so much as the Flesh. For it also hath some office. Hardness therefore and softness, clamminess, stiffness, and whatever other dispositions are in the parts animated, may be produced by heat and coldness: but that whereby it is Flesh or a Bone cannot: but it is so made by a motion proceeding from the Generator, which is actually that thing, which the thing whereof Generation is made is potentially or by way of aptitude; as we see it is also in things Artificial. For Iron is made hard or soft by cold or heat; but a Sword is made by the motion of Artificial Instruments, which motion hath in it the Nature of the Art. For Art is the Principle and Form of that which is effected, but in another. But the motion of Nature is in it self, proceeding from another Nature,*

The first Qualities are only an instrumental Agent in Generation.

which hath the Form actually. And as was said but even now, in 2. *de Generat. & Corrupt. cap.* 9. *text.* 53, 54, 55. he reckons Heat, Cold, and such like Qualities for Instruments, and saies they generate *after a very Instrumental manner*; and he writes that such as attribute Generation to them, do just as if a man should make a Saw, Ax, or any other Instrument the Cause of all those things made thereby.

Whence the Elements have their forms.

And just so it is with the Elements. For when God first created the Heaven and the Earth, he first separated the Elements, and distinguished the Earth from the Water, and so gave the Elements their forms. That therefore is false which *Zabarella* endeavors to teach out of *Aristotle Lib.* 1. *de Element. cap.* 8. 9. (where he pitifully beats his Brains and vexes himself, and yet cannot make it appear how the first Qualities which flow from their forms can be before them; nor doth he seek after Truth in the thing it self, but how he may find such an Opinion as the words of *Aristotle* can bear) that this Elementary world hath nothing of it self but Aptitude or Potentiality; and whatever it hath of act, it receives from the Heavens; and that the whol matter of this inferior world is potentially Hot, Cold, Moist, Dry; but is actually made such by Immobility the motion and of the Heavens; growing hot by the motion of Heaven, and cold by the want of that motion; and that after the first Qualities (which are the preparations for the eduction of Forms) the forms of the Elements do follow, and that so the Elements are made and continue such (according to the Opinion of *Aristotle*) from Eternity. The holy Scriptures, as hath been said, do teach us better that the Elements were created at the Beginning, and that all things have their matter and forms whereby they differ one from another, and whereby they are able to operate, from the first Creation, and preserve the same to this very day, by the good wil and pleasure of the good and great God.

Whether Forms are drawn out of the aptitude of the Matter?

From all which it appears, that God in the first Creation gave to all natural Bodies their matter and Form. To which if some would afford their Consideration, they would think otherwise than they do concerning the original of Forms. For it is an opinion sufficiently common, for which some plead as if their Life and Salvation lay on it, that forms are drawn out of the power or aptitude of the Matter, which is nevertheless built upon no sure Reasons, as I have shewed *in my Epitomy of Natural Philosophy, Book* 1. *Chap.* 3. and as I shal shew hereafter in *my Fourth Discourse touching the Original of living things*, chap. 4. Here I shal add nothing, but that this Opinion had its original from the Ignorance of the Creation of the world. For since they knew not whence all natural things should receive their forms, and that they had by command of the Creator a power to multiply themselves; they invented this original of them. Most indeed do give this out for an Aristotelick tenet, but with *Bon-Amicus* and others, Dr. *Casper Hofmannus*, a man excellently vers'd in *Aristotle*, saies it is a tenet of *Averrhoes*, in *Tract. de Origine Form. neer the end.* Yet the said *Hofmannus* in the same place doth produce some texts out of *Averrhoes*, wherein he holds the efficient cause of Generation to be the form contained in the Seed: so that the foresaid Tenet seems rather to have had its original from the Schoolmen. *Aristotle* is verily of another mind in this point, who though he admits the Heaven as an universal Cause, yet he adds an immediate Cause, when he writes, that the Sun and Man generate a man. And in 2. *Phys. cap.* 3. *text* 31. he hath these words expresly concerning Seed: *The Seed and the Physitian, and the Consulter, and whatever, is Efficient, all these are the Causes whence the Beginning of Mutation, of Rest and Motion doth proceed.* And *Scaliger* produces more such Places in *Exercit.* 6. *sect.* 2. of which also mention is made hereafter, where we shal speak *of the Generation of Living things.*

Whence that Opinion arose, of drawing Forms out of the aptitude of the Matter.

Now two things chiefly brought the School-men into this Opinion: the first it that they beleeved, as was said before from *Zabarella, Lib.* 1. *de Element. Qualitat. cap.* 9. and as they indeed suppose, according to the mind of *Aristotle, Lib.* 1. *Meteor. cap.* 4. that this Elementary world hath nothing of it self but aptitude or potentiality; and that whatever it hath of act, it receives from Heaven; and if at any time all the Elements were at first generated, and began to be what they are, they were generated by the Heavens; and because according to *Aristotle* Generation never began, that they are perpetually made and preserved such by the Heavens.

The other is because they endeavored to prove their natural Principles by examples drawn from the production of things natural (which kind of Examples though *Aristotle* hath used in his Physicks and Metaphysicks, yet we must think he intends thereby only to illustrate, not to prove that Doctrine:) for when they saw a Statue or Image made by the Carvers paring some what off, and adding if need were somwhat, and that when the Artificer had done his work at last, the very moment he leaves off the Form results from

all

al that hath been done: they thought after the same manner, that by the action of some external Agent (yet what that Agent should be they have not clearly enough explained, lurking under the general term of Nature, whereas a specifick cause ought to be rendred of every specifick Effect) some disposition was brought into the matter, upon the final perfection whereof the form sprung up in a moment: and they said that it was drawn out of the power or aptitude of the matter. But they were herein in a very great Error: For when of Wood a Bench is made, or a Statue; or a Jug is made of Earth, a Globe of Wax, there is nothing induced but a certain Accident, Quality or Shape, and there is then no power of the matter save obediential. But here the Question is concerning the original of a Substance. Yet the Production of even artificial things might have brought them to the knowledg of the generation of natural things if they would have weighed the matter more accurately. For as artificial things are produced by an actual Agent, according to a determinate Idea in the mind of the Artificer, and so every thing is not made by every Artist, but a Carver makes one kind of work, a Box-maker makes another kind: a Carpenter makes another: so also to the generation of every natural thing a determinate and specificial Agent is requisite, and one that is an Agent actually which according to the Power given it by its Creator (as the Artist works according to the Idea or Pattern in his mind) makes a work like it self. Herein only is the difference, that the Artist in the artificial generation is without the matter: but in things natural, the Artist is in the matter, and diffused through the matter as *Galen* speaks, *de Causis procat. & Causis pulsuum.* Nor can any external thing, whatever they shal feign, be admitted for a determinate cause, since none is like unto and (as they say) univocal to the thing generated, or hath at least that similitude to the thing generated which the Pattern in the mind of the Artist hath to his work, be it Statue, Pot, Bench, or what ever. For indeed Nature is an intrinsecal Art; Art an extrinsecal Nature. Now Nature hath this Art from God, the foot-steps and Prints of whose wisdom appear every where, in Men, in Bees, in Pismites, in the leaves and flowers of Trees, and al natural things whatsoever upon which the Creator hath imprinted his Image when he gave them Forms. For every Form is a participation and Image (after its manner) of the Power, and Wisdom, and Goodness, and Love of God: and every Being or thing, by its form, hath a desire to be, a Knowledg how to be, and a Power to be. And all things natural have by their forms whatever they have, and from the form proceeds the whol Fabrick of the Body, and the ornament of Accidents; and many Qualities which are vulgarly ill attributed to the mixture of the Elements and the temper of tangible Qualities do flow from the Form, and all the furniture of the Body proceeds from the Form, as I shal hereafter shew more at large in the 4. and 6. Discourses of this work.

The difference betwixt Artificial and natural Effects.

And although in the Forms of things we meet with many Particulars worthy of admiration: yet forms have chiefly three Proprieties which are diligently to be observed: The first is, that the Form of it self hath no Quantity, nor can it be divided; and the same can be as essentially entire and compleat in a smal Quantity, as in a great Bulk; and in the smallest Atome or indivisible Particle of Fire, or Water, is as perfect as in a great Quantity of either; and in a smal Seed of Poppy or Tobacco, as in a great Plant of either; or to avoid all occasion of cavilling, in a little Sprig sprouting from an Acorn set in the Ground, the form of an Oak is as perfect and compleat as in the tall and hard Oak afterwards: nor is the Soul which is in a small Seed or Shoot, lesser than that which is afterwards in a tall Tree: nor is that in an high Tree greater than that in a smal Seed or Branch.

The Proprieties of Forms.

Secondly, Yet is the form extended according to the extension of the Matter, or rather the form fils its whol Matter: For whereas, that I may demonstrate this by the Example of Plants, the whol Body of the Plant lives, is nourished, grows; the soul which was at first in a smal Twig, diffuses it self (its nature becoming no bigger) into the nourishment newly adjoyned; and where ever the Body is which lives, there the Soul is rightly said to be; and the plenitude (if I may so speak) or Replency of the Soul is just so great as the living body, and the dimensions thereof. For since no act is performed without some primary Agent; where ever there is nutrition, there of necessity the Soul must be. And because Augmentation is made, when the pre-existent Soul communicates it self to the affluent Aliment, whose Bulk reaches further than the Body which is nourished, and diffuses or sheds it self abroad thereinto; of necessity it must be present in every part of the whol Body. After the same manner the case stands in Animals. For since they are nourished, encreased, and endued with the guift of feeling; the soul which is but one, must of necessity be in all parts of the Body.

Thirdly, But although every form be of it self uncapable of being divided or parted, yet because it is coextended or stretched out together with a corporeal body, which hath Quantity, by the division thereof it becomes capable of number, and is multiplied into many Individuals, and every form hath the Power of self-multiplication. Howbeit the manner of that multiplication is not one and the same. In some Plants in which the seminal matter is dispersed through their whol Bodies, the soul though of it self not subject to Quantity, is divided after a manner peculiar to it self according to the division of the Matter, and being actually but one in number is manifold potentially, that it hath in it a fitness, power, or aptitude to become many and becomes actually manifold, when its Body is divided into many parts; of one Vine many Vines, and of one Willow or Withy many may be made. But in others this same Multiplication is caused by Seed: of which we shal speak more at large in our Discourse *of the Generation of living Things.*

Chap. 4. *Of Privation.*

Privation. I must here also ad somwhat concerning Privation, which is reckoned amongst the Principles of natural things. Since the original of the form is such, as hath been explained just now, and shal be hereafter explained more at large; Privation unless the nature thereof be rightly opened, is in vain reckoned amongst the Principles of things natural. The very Expositors (truly) of *Aristotle* themselves do grant, that Privation is not a Principle, otherwise than by accident, if you regard the thing it self constituted: but if you consider the Generation thereof, it is of it self a Principle, viz. because it is as a Term from which, (since it is the absence of the form in the immediate Matter) which hath an aptitude to receive the same: Which opinions if they are to be allowed, they do stand altogether in need of a convenient explication. For that which is wont commonly to be said, that Privation though it belong not of it self to the Essence of things to be generated, yet it concurs of it self to natural Mutations, and from it all natural Generation proceeds, so that the form doth (as it were) arise thereout; that is false. The absence of the form helps nothing to the Generation; but besides the matter a disposition to receive the form is necessary. For every Form and Soul, since from the divine Benediction it hath a faculty to multiply it self, it requires a matter wherein to be propagated, and it disposes and fits the same for it self. Plants (for example sake) produce Seeds or bulbous roots, and Eg-engendring Creatures produce Eggs, other living Creatures produce seed, by which they are able to multiply themselves and to communicate somwhat of their Essence. If they please to term this disposition Privation, they shal have my consent. But they do not cleerly enough explain how the Form follows Privation, and whence it proceeds. The Conimbricensian Collegiates do say indeed, *Lib. 1. Phys. cap. 9. Quest. 9. art. 2.* that the matter then only attains an immediate and compleat aptitude, when it is arrived to the Term and Fulness of all the Accidents wherewith it is disposed and fitted by the Agent, which term betides only in the very moment it self of Generation. And very true (indeed) it is, that disposition of the matter whereby it is fit for the multiplcation of the form is made in time, and at last perfected in a moment, nor can the Seed of a Pear or an Apple be termed properly a Seed, til the accomplishment of the accidents is presenr. But the Form is not absent while these previous dispositions are made, so as to result upon their accomplishment; but it is already present, and it self according to the nature of the Body whereof it is a form, fits the matter wherein it may multiply it self, and elaborates the same, and in this elaboration some space of time is spent, more or less according to the Nobleness or Baseness of the Forms: but when it hath introduced the utmost perfection and accomplishment into the matter, just then the Form which before had a power to multiply it self, doth multiply it self actually; as for example sake, in a Poppy look how many seeds are generated, so many times doth the form of the Poppy multiply it self, and so new Plants of Poppy are generated. The soul in an unripe seed is not different from that in the same seed when it is ripe; but herein lies the difference, that the seed unripe lives only with the soul of the Plant; and being separated from the Plant wherein it was bred it cannot exist of it self: but a perfect and ripe seed is so disposed, that though it may be separated from the Plant wherein it is produced, yet it hath the same soul in it self, and lives now by its own soul, so that it can exist by it self. Of which matter *J. Cæs. Scaliger* saies rightly, *Exercit. 6. sect. 10. A Tree* (saith he) *engenders, when it produceth seed. But the Tree is not then generated when it sprouts out of the seed; but then that which was formerly ingen-*

dred

dred and imperfect, is perfected. But if any man wil thus explain the vulgar Doctrine of Privation, and say that after the matter hath received al its accomplishment of Accidents, then there is a Privation, and that then afterwards in a moment the Form is introduced by an external Agent, that man is very much out, as shal hereafter be largely declared in its place; and it is sufficiently proved by *Julius Cæsar Scaliger, Exercit. 6. Sect. 5.*

The Nature of Privation explained.

To be brief: In the first place, Privation (however it be explained) does not belong to al Natural things, but to such alone in which there is Generation, and therefore it cannot be numbred amongst the most general Principles of Natural things. For in the Heavens there is no Privation properly so called. For since it supposes a subject having aptitude to another Form, there is no such aptitude in Heaven.

Secondly, Privation (which also the Expositors of *Aristotle* themselves do teach, as may be seen in *Tolet. Lib. 1. Phys. cap. 9. Quest. 21.*) is not a Principle of Constitution, or which enters the thing generated, to help make it up, but of Generation.

Thirdly, Though it should be admitted for a Principle of Generation; yet they who maintain the Doctrine of the Eduction of Forms out of the aptitude of the matter, cannot conveniently shew what Privation is. But if we hold the multiplication and propagation of Forms, Privation may (not unfitly) be explained two manner of waies.

First of all, Since Forms are propagated not without Matter, but with it, and every Form requires a peculiar matter; that same last disposition to the reception and propagation of the Form may (not altogether unfitly) be called Privation: and it may be thus defined. Privation is the absence of a Form in a Matter which is immediately fitted to receive the same. To explain the thing by Examples: In a Stone there is no aptitude to receive the form of an Apple, or of a Dog; and therefore we do not say there is the Privation of the form of an Apple or a Dog. So neither is the Soul of a Dog propagated with his Blood, nor the form of an Apple with the pulp or meat thereof, but with the seed. And seeing the seed is not generated in a moment; for examples sake: The seed in an Apple is first white, and then it becomes black and ripe, and apt to receive the Soul of an Apple into it, and also to retain the same, being separated from the Tree: in the seed already ripe, and which hath already in it the soul of an Apple, Privation is not said to be because the Soul is already therein; but in that same seed which is just ready to ripen and is immediately fitted to receive the Soul, and to retain it, though it be separated from the Tree, Privation is said to be; and then Privation is that same ultimate disposition of the seed whereby it is fitted to receive and propagate the form of an Apple.

Secondly, Because nevertheless in that same ripe seed the Soul is present, at least in its first act, and because it wants Organs is not vulgarly called an Apple-tree, as an Egg is not called an Hen for the same Reason: If any man by reason of the absence of those Organs necessary to perform the actions of an Apple-tree or an Hen, shal cal that disposition which is in the animated seed and Egg, to receive the Organs, and exercise the actions by a second act, Privation; and hold that in the Eg there is the Privation of an Hen, because there is therein an immediate aptitude to become an Hen, consisting of a Soul and perfect Body, I wil not quarrel or contend with that man; provided he grant, that in such a Seed and Egg there is not simply a privation of the Soul, since it is there not the first act, but the Privation of a Soul furnished with bodily Organs necessary to perform its actions.

And truly, I see the most learned Aristoteleans when they perceive the Tenet of *Aristotle* cannot be otherwise explained or defended, they can find in their hearts to embrace this Opinion. It is one and the same thing they say, which *Aristotle* names Privation, and which also he names the Form, whose absence, after its manner, is Privation, viz. In a divers respect. *Scaliger, Exercit. 6. Sect. 5.* There is in the Seed the forming Soul, going before the Soul for which it prepares that House; or as *Zabarella*, in his B. *de facult. anim. cap. 11.* speaks, the animated seed is a certain Matter cut off by the Animal it self which ingenders, retaining an active power able to generate a like Animal. For the seed of a Man hath an implanted force in it, whereby (as *Aristotle* saies, 2. *Phys.*) the Humane Nature is not as it were a Form, but as an Artificer, or immediate Agent. And therefore (in the former respect) it is an internal Principle of the thing to be formed; and although it do not inform that compound which yet is not; yet it informs the Seed so as to give it the name of a Mans seed, a Dogs seed, an Horses seed, &c. And therefore *Aristotle* cals Privation the Form as it were 2 *Phys. cap. 1. t. 15.* in respect of the form considered after the latter manner, viz. of the Compound. Inasmuch therefore as it disposes the Matter, and is the Architect of the parts to be formed out of the seed, so far it is termed Privation. And it is in reality a substance, and it is only termed a *Non Ens*, or a Non-being, in respect of the Form which shal animate

the

the parts generated out of the seed. For it hath not yet the Office of a form. So that passage in *Lib.* 2. *de Generat. animal. cap.* 1. is to be understood with a grain of Salt, where *Aristotle* tels us, that the Soul is potentially in the seed. For as the parts of the Body are not actually in the seed: so neither is the Soul in the Seed as a Form, so as to give Essence to the parts of the compound, which are to be framed out of the Seed. Mean while it is actually in the Seed, as a principle of acting, that the living thing may be generated, as *Aristotle* professedly discourses in the foresaid place. To which purpose also *Julius Cæsar Scaliger* in *Exercitat.* 6. *Sect.* 5. thus writes. *Concerning this matter we are thus to think: That the Form is in the seed of a Dog, in the aptitude whereof it is said to be; because the Seed is able to give that Form which it hath in it self. Now it is reduced out of that remote aptitude which is the first act, to a neer aptitude which is the second act,* viz. *That the Form may be in the same Matter after such a manner as to need no helps to enjoy its end for which the whol Compound is ordained. It must therefore be declared after what manner it is brought forth by preparation; in case the Form it self be author of that preparation. For the Form does both alter the whol, and order the parts for its own accommodation. The Form therefore should draw it self forth. Therefore they said not well; That when it shal attain the greatest perfection of preparation, then also it shal arrive to the substantial Form. For the Form it self exists before that: therefore it does not arrive to it, but to the act thereof, whereby it may afterward enjoy the use and benefit thereof.* After which manner if any man wil explain Privation, I willingly shal allow thereof. Yet this is certain, That the vulgar Doctrine of Eduction of Forms cannot stand with this Opinion.

Chap. 5. *Of the Consent and Dissent of things Natural.*

There is a Consent & Dissent of Natural things.

NOw as the Forms are the first Cause of al Actions; so in regard of their Forms there is a Consent and Dissent of al Natural Things, and some things have a friendly appetite one to another, and unite themselves; others are averse one to another, and fly one from another. *For things like do exceedingly covet Union. For that which is not one is not at all. So, that which is separated from its like seems also to defraud the same, and that it is defrauded thereby of the compleatness (as it were) of its Essence; for I do not say they are two fires, but one divided:* As *Scaliger* writes, *Exercit.* 310. *Sect.* 2. Seeing therefore every thing requires its own Conservation; it attains the same by shunning things contrary, by moving to things like, and by drawing like things unto it self. Hence Fire unites to Fire, but flies from Water; and Water unites to Water, but flies Fire. Hence Water sprinkled in the Air or on dust gathers it self into round drops like balls to defend it self from the Earth and Air. Hence a smal flame is most swiftly drawn to a greater, or a little flame does move it self to a greater. The same is done in the Air. Hence those Bubbles which are made on the Water do move one to another, and so much the faster by how much they are neerer. So (as *Pliny* writes, *Lib.* 2. *cap.* 105.) *Naphtha* is of great kin to Fire, and the Fire leaps to it if it come neer the same. So they report *Medea* burnt her Rival, her Garland taking Fire as she came to the Altar to Sacrifice. Hence we see that if Water be sprinkled into boyling Oyl or Tallow, or melted Lead or Antimony, the fire flies from the water as an Enemy, raises a flame and mounts aloft; so that somtimes water poured into boyling Oyl or Tallow, hath been the occasion of setting Houses on fire. And here *Hieronymus Fracastorius* is of a different mind, who in his Book *de Sympath. & Antipath. cap.* 5. denies that one thing is moved to another by reason of similitude, so that it may be united hereto and preserved; because the part separated can neither by knowledg, nor by Nature, be moved to its like part. And that it knows not, he thinks it a cleer case. But without Reason. For as there is a certain Natural Appetite which they commonly cal Instinct Natural: so there is a certain natural knowledg distinct from sense and understanding. For nothing can seek after any thing as pleasing, or flie it as displeasing, unless it have some natural knowledg of the gratefulness & fitness of the one, and the ungratefulness & unfitness of the other. For nothing is desired that is not first known. By this kind of knowledg Plants do know such Nutriment as is fit for them, desire and draw the same to them; and what is unconvenient for them they let alone; and that which they have drawn, they turn some of it into Bark, other some into Fruit, other some into other parts. Of which *Hippocrates, de Nat. humana, text.* 31. *Such things as grow and are sown, when they come into the Earth, every one draws that which in the Earth is most familiar thereto, as there is bitter, sweet, sowr,*

A Natural Appetite, & a Natural Knowledg.

sowr, and all kinds. So in the Crisis of Diseases, by a Natural Knowledg Nature knows and expels a vitious humor, and retains the good and profitable. By this Natural Knowledg Nature many times seeks strange and hidden waies to expel humors. And amongst the principles of the Nature of things *Galen* reckons this also from *Hippocrates*, 1. *de facult. nat. cap.* 12. That Nature performs al things artificially and justly, as being furnished with Faculties whereby al the smal particles do draw convenient juyce to themselves, and when it is drawn they make it grow and stick to every part, and at last assimilate the same; and what in the mean while they have not been able to vanquish, and that which wil receive no alteration, nor become any waies like the thing which is to be nourished; that they reject by another faculty, viz. the separative. And in the same place, *Lib.* 3. *cap.* 13. he writes: That al the particles of the whol Body have a power to draw to themselves that which is agreeable and friendly to them, and to force back that which is burdensom and biting. And therefore *Fracastorius* labors in vain to shew how by a certain violence such things as are separated one from another may be again joyned together. Now although this Natural Consent and Dissent of things does spring primarily from their forms: yet because the Forms do act by Qualities; some things also consent or dissent by manifest Qualities, as Water and Fire, and others by occult or secret Qualities, of which we shall speak hereafter.

Examples of the Consent and Dissent of things.

And from this Consent and Dissent of things Natural a reason may be given of many things which happen in Chymistry and Physick, and every where in the world. Salt things are mixed with salt, and dissolved by salt things; Oyls mingled with Oyly, Fat, and Sulphureous things. For examples sake, *Aqua fortis* dissolves Metals, yet can it not dissolve Brimstone: contrarywise, Brimstone is dissolved in Oyl which cannot dissolve Metals. So Gums and Sulphureous fatty Tears of Plants are dissolved by Oyl; but such things as are of a watry substance are dissolved by Wine and Water, not by Oyls. 'Tis a common Practice for a man that hath fouled his Hands with Pitch not to wash them in Water, but in Oyl or Grease, which wil dissolve the Pitch. And every where in the composition of Medicaments such things occur, especially in the making Plaisters, which if the Apothecary be ignorant of, he wil lose both his labor and materials. Also precipitations so called do afford a rare document hereof; when Gold, Silver, Corals, Pearls, Crabs-Eyes, and such like, are dissolved and precipitated. To speak only of Corals and Pearls; for examples sake (for the same reason holds in al) these Bodies are dissolved by the Salt of distilled Vinegar, or the like sharp Liquor, whereunto that same Body in regard of affinity is so joyned and united by the most subtile Atomes, that it may be strained through a brown paper. To this Liquor (containing in it the Body of Corals and Pearls) if you drop in Oyl of Tartar made by *deliquium*, or Oyl of Vitriol, the Salt of Solvent Liquor unites it self to the Oyl of Tartar or Vitriol by reason of affinity, and leaves the dissolved Body; which being so left unto it self descends to the bottom by its Natural heavines, which they cal precipitating. Also how great the force of Gunpouder is there is no man ignorant; and that proceeds only from the antipathy that is betwixt Brimstone and Salt-peeter. From the same proceed Lightnings, Thunders, and Thunder-bolts. For if in the Globe of the Earth Sulphureous, Nitrous, and watry Vapors are at once raised aloft, in the lowermost Region (truly) of the Air, where it compasses us about, being dispersed into very smal atomes, they fight not together: but when in the Clouds the fiery atomes or particles are joyned with fiery, the sulphureous with sulphureous, the watry with watry, at last resuming Courage on both sides they fight furiously, and both fly from, and chase away their Enemy. Hence the Fire shunning the Water Lightens out of the Clouds. From this Fight rumblings and Thunder-cracks are raised, and that same Fiery and Sulphureous Spirit breaking out of the Clouds melts, burns, or throws down whatever it meets with. Also there is a vulgar example hereof in Quick-lime, upon which if Water be poured, the fiery atomes which lay hid therein flying the water as their Enemy do break forth. Whereupon being collected they have raised so great heat, that they have been known to set on fire some wood that was at hand. Also if you put Spirit of Nitre to Butter of Antimony, or Oyl of Vitriol to the filings of Steel or Iron, there arises a boyling and a noise, yea, and a flame too. Where nevertheless it is to be noted, That it is credible that this same boyling is not caused only by the fight of Contraries, but also by the sudden motion of like parts to like. Also from this Consent and Dissent of Natural things many Questions in Physick may be answered, and Controversies composed. That Burns are cured by burning things, viz. by holding ones burnt hand against the fire, or by smearing the burned parts with Linseed Oyl, or an Oyntment made of Onions; and parts nummed with cold, by rubbing them with Snow, or dipping them in cold water;

Precipitation.

The cure of persons burnt, and such as are frozen and with cold.

and that Apples or Eggs being frozen, are cured by putting them in cold Water: all these effects happen because hot things draw hot things to themselves, and cold things draw cold things. Also Physitians dispute about the temper of Camphire, while the Ancients say 'tis cold, and most late Writers hold that it is hot. Howbeit the taste and its aptness to burn do so manifestly convince it to be hot, that I wonder any man can doubt thereof. The only thing which perswaded others that it was cold, is because it does cool. But this it does, not of it self, but by accident, viz. Whiles it draws the fiery and sulphureous atomes, out of the Body unto it self, by reason of similitude: which the flowers and water of Elder do in the Rose or fiery Inflammation so called, as also Oyl mixed with Lye.

The temper of Camphire.

Chap. 6. *Of the Matter of Natural Things.*

NOw, as God created al the Forms, so he gave unto them Matter, such as was fitting for every Form; and that there might be an interchangable course of things, and alwaies fit matter for sundry Forms, God created the Heaven and the Elements. The Heavens, that by their Influence they might cherish and govern the Generations of inferior Bodies; and the Elements as simple Bodies, which by their actions might further the interchangable course of Generations and Corruptions, also might afford matter to living Bodies.

Whether there is any other matter of Bodies besides the Elements?

But whether there are yet other simple Bodies besides the Elements, which may afford matter to living things, is made a Question, not without cause. With the Peripateticks indeed it is out of question, that there are in this sublunary World no simple Bodies but the Elements; and that of them al others are compounded. Howbeit, many have doubted hereof, and that not without cause. *Johan. Francisc. Picus Mirandulanus*, in his Book of Elements, chap. 3. writes: *If there be any that will not content themselves with the Opinion and Authority of the Philosophers, and will maintain that there are yet some other Elements mixed with those vulgarly known, which by a secret power of Nature concur to the constitution of sublunary things, they can hardly be substantially refuted.* And *Jacobus Schegkius*, in his Book of the Power and Efficacy of Heat, chap. 4. writes, That every Body is either an Element, or compounded of Elements, or hath some proportion and similitude with the Bodies Cœlestial. And that he had out of *Aristotle*, who in 2. *de Generat. Animal. cap.* 3. writes, That the heat in living things is neither fire, nor hath its Original from fire, but is of analogy to the Heavenly Matter. But what that Body is, and whence it had its Original, cannot be explained without the Creation of the World. But from the Creation of the World all these things are clear. For God did not at first command the Elements to fight together, to make up mixt Bodies, of which afterwards Plants and living things were to be made; but as he gave to Plants and Animals their Forms and Souls, so he gave unto each of them their peculiar Bodies. Which although (for I wil not now dispute that point) they may be constituted of the Elements as to their matter: yet that there should be nothing in them but Elements, and that the forms of these Bodies are Elementary, and that the Souls of Living Creatures are received in a Body simply constituted of the Elements; and that so the Elements considered either as simples, or as mixt Bodies, should be the immediate subject of Souls, there is no firm demonstration to prove; nor is it yet proved, That that which *Aristotle* saies holds proportion to the Element of the Stars is a meer compound of the four Elements so called. For since more noble Forms do require a more noble Matter (as *Aristotle* also teaches) the Creator gave to every Form a convenient Body, each of which receives its nobility and activity from the Form, which (as *Scaliger* speaks, *Exercitat.* 307. *Sect.* 20.) is a fift Nature, far differing from the four Elements. And in very deed, that Spirit which is inbred in Animals and Plants is a wonderful thing, which first is in a smal quantity of seed, and afterwards by means of the Blood flowing in at the first formation of the yong one, and then by the Aliments taken in it is encreased to a great bulk, and goes al over the whol body of an huge Animal, and warms and enlivens the same so long as the Creature lives. And although this Spirit be of its own Nature hot, yea, and heat it self, though the admixture of other things with it makes that it is not discerned, yet is it really in them; and it may be separated from them, as appears in Spirits made out of Plants. Where this is also to be noted, That as nothing is nourished but what hath life, as *Aristotle* teaches, 2. *de animal. cap.* 4. *text.* 46. so nothing can properly nourish, unless it be a part, fruit, or effect of a thing animated or endued with a Soul; and therefore in al aliments there ought to be some of that Spirit which they vulgarly cal *Calidum innatum*, or inbred heat; and there

their food does not only restore the moisture, but the heat also.

Nor do other Bodies which seem to be only mixed and not animated arise from the mutual fight of the Elements. It is a point of smal discretion to beleeve that Wine, Oyl, Honey, Sugar, do arise from the mutual fight of the Elements. The truth is, God did not create those things at the Beginning. For there is no Wine before Vintage, nor Oyl til the Olives are gathered, bruised, and pressed; nor Honey before the Bees make it, nor Milk before living Creatures that bring forth live yong ones become with yong. But God created such things in their Principles, that is to say, he gave a power to the Vine to make such a Liquor as Wine out of the nutriment it draws out of the Earth, the Olive tree such a juyce as the Oyl, a Reed to breed such a juyce as we cal Sugar; and to the Bees he gave power to gather juyce out of Flowers, and thereof to make Honey; to the Dugs a faculty to make Milk.

And here the Chymists bring in their Principles, concerning which I have spoken largely in my Treatise of the Consent and Dissent of the Chymists with the Galenists and Aristoteleans. That I may say a little of them in this place; first of al, those who do not simply allow them as Elements, do grant them to be the first mixt bodies. About which I wil contend with no man, if I may but obtain thus much, that in such a Sence they may be called Principles, because in the resolution or separation of mixt bodies Art can hardly proceed any further, yea, and perhaps Nature goes no further, which when she makes a mixt body does not immediately constitute the same of the last Principles, but rather of these first mixt bodies: whereof I shal speak more hereafter in my Third Discourse concerning Mixture. And this is most of al manifest in the Nourishment of Living Creatures. For neither is the *Chylus* made immediately of the Elements, but of Bread, Flesh, Fish, &c. Nor is Blood made of the Elements immediately, but of Chyle, as we shal shew more at large when we come to speak of Mixture.

Moreover, this also is worthy our Consideration, Whether those first mixt bodies do consist of the Elements only? or whether they received from God in the first Creation a Form different from the Forms of the Elements, since God created not the first matter only, but also the second, and gave every Form its proper matter and subject, by which they preserve themselves, and remain entire in the sundry Vicissitudes of Generations, and being variously mixt do afford matter to other natural things. Truly as the Expositors of *Aristotle* are too long in their Disputations of *Materia prima* or the first matter, so are they over-sparing in the Consideration of the second Matter, whereas every Form does nevertheless require its peculiar matter or subject. For neither can every body be the proper matter and subject of every form, especially of Souls, but in living Creatures it must be so disposed of necessity as that it have an immediate aptitude to receive a Soul, and to be converted into the substance of a living body, and to be nourished by the nutritive faculty. Which disposition proceeds from the peculiar Forms. Now that there are in Plants and in living Creatures forms distinct from the Soul, which belong to the proper Constitution of the Subject of Souls, is also sufficiently manifested by the wonderful operations of dead Plants, and the parts of dead Creatures in Physick. For since every action flows primarily from the form, and these actions are more noble than that they can proceed from the forms of the Elements, either simple or mixed; of necessity there are other forms besides the forms of the Elements, from which these actions proceed; and I see no cause why I may not cal them with *Scaliger*, a fift Essence, and the Body wherein they are, with *Aristotle* and *Schegkius*, a thing answering to the Element of the Stars; And some of *Aristotle*'s Interpreters (among whom *Zimara* especially) do hold, That not only Souls are super-added to the Forms of the Elements, but also that the form of mistion is a fift form really distinct from the forms of the four Elements, and super-added to them.

There are Forms super-added to the forms of mixt Bodies.

Hence, Whereas they say, That some bodies are simple, others compound, and that some are more, others less compound; that does not come to pass by reason of the first matter and Elements, but in respect of the Forms. For since al mixt Bodies consist of the four Elements, in that respect one is not more compound than another. But because some forms do presuppose other some, and cannot perform their operations save in a subject after a certain manner disposed by other forms: such Bodies which contain divers forms besides the Elements are termed Compounds, such as are the Bodies of al living things. Hence that form is most perfect which hath most other forms under its Command.

THE SECOND DISCOURSE.

Concerning the occult and hidden Qualities.

Chap. 1. *What hidden Qualities are.*

SInce to Know is to understand a thing by its Cause, we must labor with all our might, that in the things of Nature also we may render the true and proper Causes of all operations and effects. That there are indeed in nature four Elements, and that they work by their first qualities (so called) which are obvious to the Sense is a thing out of Question. But there are very many Effects in Nature which can no waies be referred to those Qualities. And therefore the most acute *Julius Cæsar Scaliger* in *Exercit.* 218. *sect.* 8. ingenuously and freely writes, that to reduce al Effects in nature to the first qualities is extream Impudence. And those who endeavor to do so, it happens to them as *Galen* writes of *Epicurus* and *Asclepiades*, in *Lib.* 1. *de natural. facultat. cap.* 14. that either they alleadg fooliſh and ridiculous reasons, or deny those things which are confirmed even by Experience, and as *Thomas Erastus de occultis medica. proprietat.* writes, they get nothing but to be derided by all that are studious of the truth and knowing in the things of Nature. And therefore *Galen Lib.* 11. *de simp. med. facultat.* when he treats of the vertue of the ashes of River Crabs against the biting of mad Dogs, acknowledges their said faculty proceeds altogether from their whol substance, and reprehends his Master *Pelops* because he boasted very ambitiously, that he knew the Causes of all such things; and promises that he would at one time or another write a Book concerning such things as act by the propriety of their whol substance. And if there were nothing else to perswade us how vainly and rashly many have endeavored to reduce all things to the first qualities, Poysons at least and their remedies might teach us so much, as the same *Scaliger* tels us in the place fore-alleadged. I for my part do freely and boldly pronounce, that there is hardly any more pernicious opinion, and which hath more wearied even the best wits and worn them out with vain and fruitless labor, than that of those men who endeavor to assign causes of all things which happen in nature from the four Elements and natural Qualities. For whether you consider them as simples, or however mixed and remixed, and however you may suppose their Qualities to be tempered, nothing can proceed from them but what is Elementary. And it is al one whether more or fewer come to sup without money, for they must all fast. But this error hath been hitherto sufficiently common, nor hath it kept it self within the bounds of natural Philosophy, but hath also crept into Physick, whiles many men have vainly endeavored to fetch the differences of all Diseases, their Causes and Symptoms, with the virtues of medicaments, from the first Qualities.

Fernelius defends occult Qualities.

But in very deed, certain most experienced Physitians have long since acknowledged this Error and warned others thereof, amongst the rest *Johannes Fernelius*, a most excellent Physitian, who *in two Books de Abditis rerum Causis*, hath most learnedly demonstrated, that many things are, and are performed in Physick, whose causes 'tis vain to draw from the temper of the first Qualities. For which excellent pains nevertheless of his he hath gained nothing from some but reproach and back-biting. And no wonder; for the world is governed by opinions: and many think it not very honorable, yea and a foul disgrace too, to

lay

lay down the Errors they have unwarily drunk in, and to admit and acknowledg the truth, though it dazle their Eyes with its most cleer brightness; and therefore whatever they are ignorant of they esteem as new and false. Mean while all more learned Philosophers and Physitians have undertook to defend the truth, and have constantly taught, that the Causes of many things in natural Philosophy and Physick do depend upon hidden Qualities, and that we are glad oftentimes to fly to the saving Sanctuary (as *Scaliger Exercit.* 218. *sect.* 8. names it) of an occult Propriety: which whiles it is called ignorance by some, they rather accuse the weakness of our understandings to dive into the secrets of Nature, then blame these hidden Qualities. For if the true Original of these qualities be sought into, (whereof few have taken care) the knowledg thereof wil produce as certain science as that of the first Qualities. For the natural Philosopher knows no more of Heat, but that it Heats, and that it flows from and depends upon the form of Fire: which form is to man as unknown as those forms from whence the hidden qualities arise. For as *Scaliger Exercit.* 307. *sect.* 29. saies, The Form is a divine thing, the perfect knowledg whereof is hidden from us, and therefore to search further is the part of an unquiet and over-busie mind. And therefore those who traduce these Qualities, by calling them the Sanctuary of Ignorance are long since worthily refuted by *Avicenna, Lib. de virib. Cordis, tract.* 1. *cap.* 10. when he thus writes: As he that knows fire warms by reason of the heat therein, truly knows and is not Ignorant: so he that knows the Load-stone draws Iron because it hath a virtue in it whose nature is to draw Iron, without doubt is knowing, and not Ignorant. *And afterwards*: The Ignorance of the Causes of this Virtue in the Load-stone is no whit stranger than the Ignorance of the Causes disposing things be to red or yellow, or the Body to the Soul. But admiration ceases in things we are used to, and our mind neglects to enquire concerning them. But that which happens seldom stirs us up to admiration, and moves us to enquire and contemplate the causes thereof. *And a little after*: If that Fire were a thing hard to come by, and brought from far Countries, People would more admire the properties thereof than the properties of other Bodies, and more enquire into the Causes of its proprieties than into the Causes of other Proprieties, because its proprieties are very wonderful. For the presence thereof brings the sight from aptitude to act, and it will not suffer it self to be touched; also it mounts upwards, and makes such things as it can master to ascend with it, and of a smal quantity thereof in the space of an hour a great quantity is bred; and it corrupts every thing it meets with, and changes it into its own substance; nor is it lessened though you take some from it. And these things are in truth more wonderful than the drawing of Iron by the Load-stone, or than other Proprieties. But because these are usual, and dayly seen, we cease to admire them, nor are careful to enquire into their Causes. But the action of the Loadstone, because it is rare and unusual, induces to admiration, and provokes men to enquire after its causes. And indeed if we enquire into the original of these hidden qualities, there may be had of them as certain knowledg as of those that are manifest. For in this darkness of humane understanding the form of the Fire is to us as unknown as that of the Loadstone, and as the Poet sings.

Whether occult Qualities be the Refuge of Ignorance.

The occult qualities cause science.

The wonderful properties of Fire.

Nature's wont to hide many things with a Sacred cover:
Nor is it fit that mortal men should come to the knowledg
Of all things, since that many are more fit for a wonder.
And so far the truth of things is set from our Eye sight,
That we may hardly be said to know the things we do handle.

Now these Qualities are called Occult, Hidden, Abstrute, to difference them from the manifest qualities which are discernable by the external Senses, especially the Feeling; whereas contrariwise these are not perceivable by the Sense, although their operations are. So we see the attraction which is made by the Load-stone; but we perceive not the qualities which causeth that motion of the Iron. So we perceive with our senses the evacuation caused by purgative medicaments; but we do not perceive that quality by which the purging medicaments do work that effect. After the same manner, we perceive with our Senses the symptoms which Poysons do stir up in our Bodies; but the qualities whereby they cause the said symptoms we perceive not by the sense. By our Senses (for example sake) we perceive Heat in the Fire, by means whereof it heats: but it is not so in those operations which are performed by occult qualities. We perceive the Actions but not the qualities whereby they are affected. Hence these qualities are termed hidden and specifical proprieties, faculties proper to substance; and such Agents are by *Galen* called things acted by their whol substance, or by a propriety and familiarity of their whol substance, 6. *Epidem. Com.* 6. *text.* 5. 11. *de simpl. med facult.* and elsewhere.

the names of occult Qualities and what they are.

Chap. 2. *Whether there are occult Qualities, and things that act by their whol Substance.*

'Tis proved that there are occult qualities.

NOw that there are occult Qualities and actions proceeding from occult Qualities, is from two things chiefly apparent. The first is, That there are many actions in Nature which totally differ from the actions of the Elements; The second is, That the way and manner of the actings of such things as work by occult Qualities, is far different from that of the Elements.

The actions of occult qualities different from those of the manifest ones.

As to the first, What the actions of the Elements are, is known, viz. To heat, to cool, to moisten, and to dry, and such as follow them, to rarefie, make compact, &c. But there are actions in Nature far different from these. The Load-stone draws Iron; a Cat (though shut up in a chest) does so work upon some people that they are ready to fall into a swoun; a little Quantity of Opium stupifies a man and brings him into a dead sleep; what mischief the biting of an Asp, a Viper, a mad Dog works in our Bodies, al men know; what strange symptomes does the biting of the Spider *Tarantula* cause; of which I have spoken in the first Book of my Practice, part. 2. cap. 17. And how great the force is of a little pestilential Infection, many know to their sorrow. And these Venoms are not cured by heaters, moisteners, coolers, dryers, but only by such things as work by occult Qualities. And as was before wel said from *Scaliger*, If nothing else could perswade how vainly and rashly many endeavor to reduce al effects to the first qualities; at least Poysons and their Remedies might convince us. And a thousand such actions are every where met with in the course of Nature. Since therefore such actions are of a quite different kind from the actions of Elementary Qualities, and surpass their faculties, we do therefore justly distinguish these Qualities from those which are manifest to the Sense, and term them occult. *Galen* knew this, who writes in his 6. *Epidemic. Com.* 6. *text.* 5. and 3. *de temperament. cap.* 4. expressly, that poysons do not at al act after the self-same manner as fire and water, but by a contrariety of their whol Nature. And *Lib.* 5. *de simplic. medicam. facult. cap.* 1. 18, 19. he writes, That there are some things contrary to us by their whol substance.

Also the manner of acting is different.

Again, The Elements have a much different manner of acting from that of those things which work by occult Qualities. For the Elements (to exercise their Faculties) require a sufficient bulk of Body, nor can they exercise their forces in a very smal quantity. For though fire be extreamly hot, and Snow extreamly cold; yet as *Galen* wel writes in his 1. *de Temperamentis, cap.* 4. a very smal quantity of either of these works no effect in our Bodies; yea, bodies so qualified do not kil a man though taken in a good quantity, whether hot or cold; as Snow, Pepper, cold Water. Again, they do not work such sudden mutations in the Body. But some Poysons kil a man in the smallest quantity imaginable, or stir up most grievous Symptomes, and that in a moment. Of which *Galen*, *Lib.* 1. *de Semine, cap.* 16. thus writes, *The smallest portion of a deadly poyson being entred into a man or other Creature, does change it totally in a moment of time, and qualifie the same with a disposition like it self.* Again in his 3. *de locis affectis, cap.* 7. he saies, *Who would beleeve that from the stinging of a Scorpion, or of the* Philangium *(a Spider so called) the whol body should be so exceedingly and unusually changed, unless he had often seen the same with his Eyes, especially considering the sting of those Creatures is a very smal thing.* And a little after: *The sting of a Sea Turtle, as also of a Land Scorpion, does end with an exceeding smal point; where there is no hole through which the poyson might be cast in: yet we must needs suppose that there is some substance in the Nature of a spirit, or of a Liquor, which though very smal in bulk, yet is very great in activity.* And *Ælian* in his 9. *B. de Animal. cap.* 7. relates, that the prints of the biting of an Asp are so exceeding smal that they can hardly be discerned by a sharp sight. And *Jul. Cæs. Scalig.* in *Exercit.* 153. *Sect.* 11. and *Mercurialis* in his Book *de Venenis. cap.* 16. do write, that in *Nubia*, which is a part of *Æthiopia* beneath *Egypt*, there is poyson, the tenth part of a grain whereof wil kil a man, or one grain ten men, within a quarter of an hour: or if one man take one grain it kils him presently.

Occult qualities known & asserted by learned Men.

By which Reasons most learned men being moved, have acknowledged and taught, that there are very many Qualities in Nature, besides the Elementary. *Galen* (as we said before in the beginning of our first chapter of this Discourse) in his 11. *de simpl med. facult. cap.* 14. where he treats of the vertue of the Ashes of River Crabs against the biting of a mad Dog, reprehends his Master *Pelops* that he vain-gloriously boasted that he knew the causes of al such things:

things: and in his first *de nat. facult. cap.* 14. concerning *Epicurus* and *Asclepiades* he writes, That those who endeavor to bring manifest causes for al Diseases, it commonly fals out, that either they bring foolish and ridiculous reasons, or deny those things which even experience it self confirms. And in the third B. of the faculties of simple Medicaments, chap. 3. he writes; And truly it is by us in other Treatises demonstrated, that there are in all things certain Agreements and Repugnancies of Qualities, and that which is familiar is readily assimilated, but that which is contrary kils both Plants and Animals; also that these familiarities proceed from the propriety of the whol substance. And in B. 5. *de simpl. med. facult. cap.* 2. we have shewed (saies he) that Medicaments have a faculty to alter, either by one quality, viz. By heating or cooling, moistening or drying, or by some of the said qualities joyned together, or by their whol substance; as most deadly poysons, many Antidotes or amulets, and al Purgers. Which also he repeats in the same Book, chap. 17, 18, 19, 23. The same he teaches in the 6. 8. & 9. *de simp. med. fac.* the 1. *de compos. med. secundum genera, cap.* 16. the 8. *de compos. med. secundum loca, cap.* 8. the 13. *de Methodo medendi, cap.* 6. *Alexander Aphrodisæus* writes in his Proeme to the Problems, that there are in these things in Nature, which can be known only by experience, and are therefore by Physicians termed Hidden Properties; and he reproves those who endeavor to render the Causes of such things from the qualities of the Elements, and that they scurvily botch up certain solutions which are altogether unprofitable and improbable: whom *Mesues* and other Arabians do follow. But in the Age last past, *Johannes Fernelius* that most learned Physician does largely and learnedly maintain these Qualities in his 2. Books *de Abditis Rerum causis*; who in the Preface to his second Book thus writes. Many indeed laugh at the Atomes of *Democritus*; but *Democritus* if he were to rise from the dead would much more (after his manner) laugh at these Elements we talk of, inasmuch as some endeavor to draw the causes of al things in Nature from them. The most acute *Jul. Cæsar Scaliger*, in his 218. *Exercit.* Sect. 8. writes, That it is a point of extream Impudence to refer al things to manifest Qualities; and in *Exercit.* 101. Sect. 14. thus he bespeaks *Cardan*: What evil Alexandrean spirit hath so bewitched thee that thou shouldest pitifully beleeve it possible that the Load-stone should draw Iron to it only by the mixture of the Elements? And in his first Book of Plants, treating of Tasts, he hath this passage: But if any man shal say, That Taste is made by a conspiration of the four first Qualities, let him tel me, Whether in any Element as an Element there is any Taste? There is truly none at al. But as neither life proceeds from the Elements, nor laughter, nor sense, nor understanding, nor voluntary motion, but from other forms besides the Elementary; even so does Taste also. And though there were no other thing to perswade us that there are other occult Qualities besides the Elementary; we might be satisfied only by the consideration of Poysons. The same *Scaliger* in *Exercit.* 218. *Sect.* 8. saies: Many of them have Proprieties different from the Elementary Qualities, which are concealed from temperate minds, and delude the curious. And *Thomas Erastus* in his 4. chap. of the Hidden properties of Medicaments (which place I alleadged in the first Chapter) saies, That they who would reduce al effects to manifest Qualities do gain nothing, but to be justly derided by al that are studious of the Truth, and skilful in the things of Nature. Also *Joban. Francisc. Ulmus* hath defended, explained, and by many examples proved the said occult Qualities, in *Lib.* 4. *de occultis in re medic. proprietat.*

That which *Galen* saies happened to them that reduced al things to first Qualities, that either they brought foolish and ridiculous Reasons, or denied such things as were evident, that also happened to *Sanctorius*, who in his *Lib.* 8. *Methodi Vitand. in Medicin. Error.* endeavors to reduce hidden and occult properties to manifest qualities: Whose Discourse of that Subject I think fit briefly to propound and examine.

Sanctorius *his Discourse of Hidden Qualities examined.*

But at first, in *cap.* 3. by way of a Ground-work he premises that Question, Whether the Faculties of the Soul do essentially differ from the substance of the Soul? or Whether they are in the same predicament therewith, viz. in the Predicament of substance; and he conceives the Fountain of that error concerning occult qualities to be, that those who hold there are qualities of the whol substance, do conceive that they belong to the predicament of substance. For suppose indeed that some there were who conceived the Faculties of the Soul differed not from the Essence thereof; yet they held an Error. And herein we willingly assent to *Sanctorius* when he holds the powers of the Soul are not substances; but that they differ from substances and are qualities. But if such things are sometimes by Authors attributed to Faculties which are proper to substances, there is an equivocation in the word *Potentia*, power or Faculty, which sometimes (and that properly) is taken for a quality, but

sometimes

somtimes (though improperly) for a substance, having a power or faculty to act. And such substances are not only Souls, but also other forms, as that of the Load-stone. For all forms are substances which have their powers of exercising certain actions, all which they do not perform by manifest, but some by Hidden Qualities. He labors therefore in vain chap. 6. while both by Authorities out of *Galen*, by reasons and experiments, he endeavors to prove, That hidden Qualities proceed not from the substance, but from the manifest Qualities. For in the first place, that which he brings out of *Galen*, 12. *Method. Medend.* and other places, that occult qualities have their contraries, but substances have no contrary, is of no moment: for the occult Qualities are not substances, but qualities flowing from their forms. And if there be any other such arguments, they touch not our Opinion, but that of *Fernelius*, who holds Diseases of the Form. Moreover, that which he brings out of *Galen*, *Lib. de Constit. Artis*, *cap.* 8. and 4. *de simpl. med. cap.* 15. and 2. *de locis affectis*, *cap.* 8. deducing unutterable proprieties from sundry alterations, all that we grant. But if only the first qualities be mixed, no occult qualities can arise from thence, but only a temperament of the first qualities; though the degree of the temper or mixture cannot always be sufficiently explained. So, when he saies, that of bitterness, sweetness, harshness, and acrimony mingled there arises a quality, which because it cannot be expressed by one name, may be termed ineffable or unutterable, al that we grant; but yet no occult quality, such as is in the Load-stone, Poysons, and such like, does thence arise, but only a tast, being only a manifest quality perceivable by the Tongue. Of the same moment is that which he alleadges as an experiment, that out of divers colors mixed peculiar colors arise. For whatever colors are mixed, nothing arises therefrom but color; but no occult Quality. And although of an hundred other altered qualities the determinate degree cannot be known: yet the power of drawing Iron which is in the Load-stone cannot be made thereof as he falsly conceives. Out of the first Qualities only temperaments of tangible Qualities are made, though the determinate degree is not always known; out of colors colors, out of Tasts Tasts are made. But never out of the first qualities, or tasts, or colors, can be made the power of drawing Iron, or of purging, or of stupifying like Opium, or such as is in the Venom of the Pestilence. From al which it is manifest that *Sanctorius* hath not rightly formed the state of the Question, but dallied with the equivocation of the words Ineffable and Occult Quality, and was ignorant what that Occult Quality meant which is intended in the Question.

Sanctorius his arguments examined.

But whereas in the seventh chap. he labors to find out the differences of Occult Qualities, therein he does wel in that he labors to fetch them from the Subject; since the condition of al qualities depends upon the first Subjects. But when he endeavors to deduce them from the first manifest Qualities, and second, as Heat, Cold, Moisture, Driness, Rarity, Density, he makes himself a laughing stock. For whereas in the first place he conceives the proper subjects whereby the Qualities may be defined may be taken from a substance considered as corporeal; he is exceedingly out. For from a Substance as Corporeal nothing proceeds but quantity and dimensions. But on Bodies not considered as Bodies, but as furnished with certain Forms, the occult qualities and all others depend. Moreover, whereas he makes the Principle of al Passion to be Density and Rarity, and deduces the qualities both first and second, hot, cold, moist, dry, hard, soft, stiff, crumbly, rough, smooth, thick, thin, from Rarity and Density, that therein he is in an error is so clear that it needs no proof. And let it be granted (truly) that those Qualities proceed from Density and Rarity: yet all these qualities are not occult, concerning which our question is, but tangible qualities. And that is yet more absurd, that he endeavors to bring al from Scituation, and saies that Scituation is the general kind of al: For from the Scituation of the parts of a Body proceeds Rarity and Density, and from Rarity and Density hot and cold, moist and dry, also hard and soft, with the passions, and passive qualities.

Of the differences of Occult Qualities.

And he becomes perfectly ridiculous when he writes chap. 10. That he saw in *Hungaria* an Italian Gentleman, who when he was near a Cat (though he saw it not) he presently swooned, and unless the Cat had been driven away would have been choaked; and he supposes the cause hereof was Compactness and straitness. For that the Gentleman was narrow chested, and apt to a Tissick, and in the Cat there were three destructive things for those in the Tissick, viz. Its Brain, Breath, and Hair. Therfore he conceives it is no marvel if of these a new stopping quality was bred which might by the exhalation of the Cat be communicated to a man, and by condensing choak him. But one absurdity being granted, a thousand follow. For I my self (and many others) have known such as could not endure the Presence of a Cat, yet are they not troubled with the Tissick. Moreover, if the destructive Faculty be

Of the Antipathy betwixt a Man and a Cat.

in

in the Brain, Breath, and Hairs, it is not Denſity. Thirdly, If Cats do this by their thickning breath, why do Cats ſhut up in a Cheſt work the ſame effect? Fourthly, Thoſe that are troubled in this kind do not complain of the *Aſthma* and ſhortneſs of breath, but only of fainting fits.

That there are Occult Qualities which ariſe not from the firſt, proved by certain Experiments.

But the beſt thing in this Diſcourſe of his is that which he hath in chap. 10. where being convinced by the Truth it ſelf, he proves by many reaſons and experiments, that there are Hidden qualities which do not ariſe from the firſt qualities, whereof I ſhal ad only ſome, viz. Thoſe which directly prove that occult qualities do not flow from the firſt qualities.

The firſt Experiment is of the Load-ſtone, which is notoriouſly known to draw Iron, which Faculty nevertheleſs cannot be reduced to any firſt quality.

Secondly, If *Doronicum* did kill Dogs by vertue of Heat or Cold, it could not cure Men.

Thirdly, If Scorpions did kil by Heat, the drinking of pure unmixt Wine would not cure their poyſon.

If a dram of *Opium* kils by its coldneſs, why wil not an ounce of Ice (which is colder) do as much?

But the reſt of the Experiments which he brings do not prove that occult qualities flow not from the firſt; yet againſt thoſe who endeavor to derive al qualities from the firſt, they prove there are qualities which flow not from the firſt. For ſince alteration and the action proceeding from the firſt qualities is not effected in a moment, but gradually and in time; and that there are many mutations of qualities which happen in a moment, thence it appears that there are qualities which are not made by mutation of the firſt qualities. For if a red Glaſs be put before a blue Glaſs there ariſes therefrom in a moment a Violet color; if a blue Glaſs be put upon a yellowiſh Glaſs, there ariſes therefrom a green color; Water wherein Galls have boyled is clear, but if Water be poured thereinto wherein Vitriol hath been boyled, which is alſo clear, there ariſes a black color in a moment; and there are many ſuch mixtures which produce a new quality in a moment.

All things are not vain which are reported of Occult Qualities.

Finally, Whereas in cap. 11. he writes, That the maintainers of occult qualities have been too credulous to beleeve the moſt vain reports; I confeſs indeed that many fabulous and ſuperſtitious tales go up and down; but in the mean time, al things are not fabulous which are ſpoken of the effects of occult qualities. Doubtleſs thoſe reports of the Load-ſtones Faculty to draw Iron, of the ſtupefactive faculty of Opium, of the Faculties of Poyſons and Antidotes, of the Antipathy betwixt ſome people and Cats, are al moſt true, and any one may dayly experiment the ſame. And whereas he accounts for fabulous al that is ſaid of ſundry things hung about the Neck, or tied to the Body, he does it without cauſe; ſince thoſe things which are reported of Peony Root, the Elks Claw, the Nephritick Stone, and ſuch like things, are known by Experience to be really true. So alſo, thoſe things which are written of the Echeneis he can by no other reaſon confute ſave that it cannot produce ſuch an effect by heating, or cooling, or rarefying, or rendring compact, or the like qualities. Others there are who account the Narration concerning the Echeneis to be fabulous; but *Pliny*, *Lib.* 32 *cap.* 1. confirms it by Hiſtories, thus writing: *The Fiſh Echeneis or Remora, held the Prætorian Ship of* Antony *in the Actian Sea.* And a little after he ſaies: *It ſtopped alſo in our Memory the Ship or Galley of Prince* Caius *as he was ſailing from* Aſtura *to* Antium. *Nor was there long wondring at that ſtay, for preſently the cauſe being known, when of the whol Fleet that Galley only did not ſtir, ſome leapt out into the water to ſeek the cauſe, and they found the ſaid Fiſh ſticking to the Rudder, and ſhewed it to* Caius, *who ſtormed that ſo mal a thing ſhould ſtop his courſe, and fruſtrate the endeavors of four hundred Rowers.*

A Story of the Echeneis, Remora, or Stop fiſh

Therefore *Franciſcus Valleſius*, *Controverſ. Med. & Philoſ. Lib.* 8. *cap.* 5. ſaies, That it is a ridiculous thing to deny that which is manifeſt by Experience, becauſe we cannot tel the reaſon thereof. As if it were impoſſible any thing might happen in Nature of whoſe cauſe we are ignorant. We are ignorant of moſt things. And therefore they that would in Natural Philoſophy find out the Truth, and not fal into wild and ſophiſtical Opinions, they muſt begin with things known to the Senſe, and ſo proceed to the Cauſes, and having found them rejoyce in the Works of Nature; and not finding them, confeſs their own ignorance; but by no means deny things that are manifeſt. For it is leſs ſhameful having found out the effect to be ignorant of the Cauſe, which is frequently hid from the moſt expert Philoſophers, than together with the cauſe to be ignorant of the effect, which when you deny, the common people wil laugh at you, and prove it by experience.

'Tis ridiculous to deny a manifeſt effect becauſe the cauſe is unknown.

CHAP.

Chap. 3. *Of the Original of Occult Qualities.*

NOw to find out the Original of Occult Qualities is a very hard thing, nor are all men of the same Opinion concerning their Rise. For in the first place, some there are who being moved with the evidence of the thing it self, dare not deny occult Qualities: but when they come to search out their Original, they fal back to the Elements and their Qualities, and endeavor vainly to derive the occult Qualities from their mixture and temperament: and conceive the hidden proprieties of things do proceed from a peculiar temper of the first Qualities, which therefore they term *Idiosyncrasia*. It is not (truly) sufficiently apparent what *Galen* thought in this point, since that Book which in *Lib.* 11. *de simp. med. fac.* he promised to write of things which operate by their whol substance, and which he cites in the 6. *Epidem. comm.* 6. *text.* 5. is lost through the injury of time; yet he seems to encline to this Opinion, and to rest much in the first Qualities. For in the 1. *de Element. cap.* 7. he writes, That our Bodies are altered only by being heated, cooled, dried, moistened; for that these Qualities only do totally change through their whol substance. And when in *Lib.* 3. *de Temper. cap.* 3. he had said that the four Faculties of the Body, Attractive, Retentive, Concoctive, and Expulsive, were in every Body effects of the whol substance; he adds, that the said whol substance consists of Heat, Cold, Moist and Dry, mingled together. And in Chap. 4. he teaches us to observe for a Principle, that every body hath a certain propriety of Temper, which is convenient to this Nature, disagreeing to that. And hence he gives the reason why several things are Food or Physick for several Creatures; as for instance, Hemlock is Food for the Starling, and Hellebore for the Quail, which are Medicaments for men; because the temper of the Starling and Quail can assimilate the Hemlock and the Hellebore, which Mans Temper cannot do. Most late Writers have been of the same Opinion, not being able to raise their Minds beyond the Elements.

The mixture of the first Qualities cannot produce the occult Qualities.

But in very deed the Occult Qualities which act beyond the power of Elementary Qualities cannot proceed from the Elements however mixed, nor from their Qualities however tempered. Nor can a hidden way of Mixture bring in new abilities, but which way soever the Elements be mixed and remixed, and however their qualities be tempered, nothing arises therefrom but what is Elementary. And the Proportion of manifest Qualities being unknown does not of manifest make them occult, but only breeds a temper wherein the proportion of the first Qualities is unknown to us. The Elementary Qualities are, and remain even under the unknown measure of a Temperament; and as in the Temper the Qualities do not change their Essence, so neither can they perform an action transcending their Vertue and activity. For that is a Rule infallibly true, That nothing acts beyond the powers of its own kind. And that Argument which *Jul. Cæs. Scaliger, Exercit.* 307. *Sect.* 20. uses to prove, That the Soul does not arise from the Elements, is doubtless general and of use here. That (saies he) is in the powers of the Soul which was never in the power of any Element. But there is nothing in any thing which was not actually in its Principles. For the Principles are the acts of those things whereof they are Principles. Now in the Soul there is a Faculty to move forward, backward, to the right hand, and to the left, which is not in any Element. There are also other more illustrious powers of the Soul, which are not in the Elements. For what *Scaliger* saies of the Faculties of the Soul, the same may we say of the Faculties of the Load-stone, of purging Medicaments, of Poysons, and other things. For nothing acts beyond the vertue of its own kind; and nothing can work as a Cause beyond its own adequate Act; since it fils the vertue of the Power. And though other vertues be in a mixture than are to be found in the simples singly considered: yet those Vertues are no other than Elementary, and which the several Elements joyned together have in them; and they are the first Qualities broken and allayed by their Contraries. For as I said before, if four or more come to sup together without every man his shot, they must of necessity al fast. For examples sake, If four colors be mixed, a color indeed different from each of the four arises, but nothing else save a color; not such a faculty as is in Scammony Opium, and the like. After the same manner, if you mix the first Qualities, and mix them again, other qualities indeed or temperaments wil arise different from simple Heat, Cold, Moisture, Driness; but no other Quality wil arise from thence, save an Elementary Quality or Temperament.

Nor let any man think to scape by saying, That the manifest Qualities and their Temperament do not indeed of themselves perform such noble actions, but as they are guided by a more

more noble ſpecifick Form. For no Inſtrument acts beyond the vertue of its kind, though it be directed by a ſuperior Agent. And therefore as an Artiſt uſes ſundry Tools, as the Carver his Compaſs, Saw, Chizel, Scraper, every of which performs its uſe: ſo every Form uſes its Qualities to ſundry actions. And as a Saw when the Carpenter uſes it does ſaw aſunder, but does not hew or pare; even ſo Horneſs where-ever it is does nothing but heat. Nor does the Load-ſtone draw Iron, nor Rhubarb purge by heat, but by an hidden Quality, peculiar to themſelves.

Nor is it credible (ſince the Forms of the Elements have their Qualities) that thoſe more noble Forms are barren, and produce no qualities, ſo as to ſtand in need of borrowing the ſervice of the Elementary Qualities. In a word, as things differ in their Forms, ſo do they in their Operations and Inſtruments.

Occult Qualities are not drawn out of the power of the Matter.

Nor do they bring any thing better or righter, who hold, That in every Mixture a new Form is drawn forth, and that there are alwaies new ones made, the degrees of the former remaining, and that with theſe there ſpring forth new Qualities, and that Nature firſt brings forth the Univerſal Forms, and by their help the particular ones, until at laſt ſhe come to the forms of Individuals; and that from this contemperation of Qualities ariſing from divers Forms and mixture of Bodies, which ſaving their forms do put on the Nature of matter (as it were) or aptitude, there ariſes (they ſay) an unexpreſſible propriety of temper, which may rightly in ſome ſort be termed an occult Quality. For, to paſs over other Errors touching drawings out of Forms, degrees of Forms, and ſuch like; theſe Men alſo favor nothing but Elements, and that which they had before rightly determined, viz. That an occult manner of mixture does introduce no new faculties, they themſelves afterwards deſtroy. For ſuppoſe that many mixtures are made, and that with theſe alwaies new Qualities ariſe: yet becauſe the firſt mixture is only of Elements, and no other temper ariſes from thence but of the firſt Qualities, though you remix things mixed before an hundred, yea, a thouſand times, nothing but what is Elementary, and no Qualities but Elementary Qualities can ariſe therefrom, and therefore nobler actions than thoſe of the firſt Qualities cannot be by them produced. And if Natural things ſhould be generated after this manner, and by the mediation of Forms (their degrees ſtil remaining) a progreſs ſhould be made unto particular Forms, and at laſt to ſuch as are iudividual; the forms of al things living, as wel living things as Plants, ſhould be drawn out of the Elements. Indeed that ſame Innovator, who dares vent the Dreams hatched in his own Brain to day or yeſter-day for the Tenets of reverend Antiquity, accounts it no abſurdity; who holds that the Souls of living things, Plants, and Animals (excepting that of a Man only) are made of the matter of the Elements, and that Plants and Animals (both as to Matter and Form) were both at firſt produced out of the Elements, and at this day have no other Nature, and remain through al Generations Elementary Bodies in reſpect both of Matter and Form. But this groſs and moſt abſurd Opinion can neither be by any reaſons proved, nor can the invincible reaſons of *Julius Cæſar Scaliger* againſt the ſame be anſwered. Which when he perceived, and that he could not find any probable reaſon for his Opinion, no not to make a flouriſh with, he flies to the holy Scriptures miſ-underſtood, and endeavors to ſet *Moſes* againſt *Scaliger*, as if he had ſaid, That al living and lifeleſs things were ſo produced out of the Elements as to conſiſt of Elementary Materials, both in Matter and Form, and to ariſe therefrom at this day; becauſe God ſaid, Let the Earth bring forth, let the Water bring forth the living Creature; alſo, Encreaſe and multiply. But although God ſaid, let the Earth produce, let the Water produce; yet by force of thoſe words it no waies follows, That Plants and Bruits were made of the Elements both Body and Soul, and are generated of them at this day; ſince God then created perfect Plants and Animals in the Earth and Water, which as *Fr. Junius* writes upon this place, came out of the Earth and Water wherein they were created, as Children out of the Womb. Nor does the Hebrew word *Hotzi* ſignifie to give matter, but to make and ſuffer to go out; as in *Gen.* 14. ver. 18. *Exod.* 8. ver. 18. chap. 20. ver. 2. *Numb.* 17. 8. *Pſalm* 68. 8. *Pſalm* 104. 14. and very many more places of Scripture, appears. Nor did God ſay to the Earth and Water, Encreaſe and multiply, but to living Creatures made by him, and having their ſeed in themſelves; whereof we ſhal alſo ſpeak hereafter in our Fourth Diſcourſe, Chap. 4. *Julius Cæſar Scaliger* ſaies much better in *Exercit.* 307. *Sect.* 20. *Yea, and I tell them withal, That the form of every perfectly mixt Body, although it be no Soul (as that of the Diamond for inſtance) is a ſift Nature, far differing from the four Elements.* And in *Exercit.* 307. *Sect.* 12. *If* (ſaies he) *as theſe Tormentors or Hangmen of Souls contend, the Souls were made of the Forms of Elements, the Forms themſelves corrupted could do more than they could when they were in their Integrity. But in caſe*

Whether the forms of Plants and Bruits ſpring from the Elements?

case they will have them remain entire in the Compound, of necessity they must be by another power different from themselves both mixed to certain ends and limited in certain bounds. For of them actually existing there cannot be made a thing simply one, save by a superior power, which Aristotle *calls the Beginning of Living things.* And al the Reasons which prove it, are most firm. For who is it that considers how in Plants, the Roots, Trunks, Leaves, Flowers, Boughs, are so wonderfully and variously shaped, according to the variety of sorts, in respect of magnitude, figure, Situation, color, and with so much Art and constant Symmetry, as that no Geometrician or Painter can express al that Art, wil beleeve that al these things are wrought by the Elementary matter? who wil beleeve that the most noble Fabrick, not only of Men, but of Bruits, is produced by an Elementary Nature? Who wil derive the Sagacity of Dogs, the Prudence (that I may so speak) of Elephants, the Craft of the Fox, the Magnanimity of the Lion, the wonderful works of Bees, Pismires, and other Creatures, from the Elementary Nature? And therefore from hence (as was said) *Scaliger* frames an invincible argument, *Exercit.* 307. *Sect.* 20. *That is in the power of the Soul which was never in the power of any Element. But nothing is in any thing which was not actually in its Principles. For the Principles are the acts of those things whereof they are Principles.* In the answering of which Argument, the forelaid Innovator takes pains to no purpose. For first, he doth seek to elude that same Axiome, That Principles are the Acts of those things whereof they are Principles, by saying that Matter also is a Principle, and yet is not the act of a thing. But who sees not that *Scaliger* speaks of the formal principle, the Cause of actions, and that the form is often termed the Principle by way of Eminence. Nor yet is it absurd to say, that even matter also in its way hath an act. Indeed it is not the act of the Compound which the Form affords, yet is it in the mean while a substance by it self; and as *Scaliger* in *Exercit.* 5. speaks, it is that which it is by an Essence proper to it self. And *Exercit.* 17. The Matter hath its quiddity whereby it is somwhat, and differs from other things. And the Matter gives Quantity to al things. But against that other Axiome, That there is nothing in any thing which was not actually in its Principles, he can bring no reason. Verily that which one hath not he cannot give to another Man, and unless the Earth were heavy, the Fire hot, no mixt Body would be heavy or hot. And doubtless, no affection can be in a Compound which may not be referred either to the Matter or the Form. Yet he endeavors to evade the same by some instances. And in the first place he objects the Heaven, how that it is al things in respect of its working power. But (which himself confesses) the Question is not concerning external efficient causes, but essential internal Principles; and the enquiry is, Whether there be any thing in the Compound which does not depend upon the internal essential Principles. Also the Heaven it self is an univeral, and not a particular Cause. Moreover he objects life which is from the Soul, but not in the Soul. But he ought to have observed what very many of *Aristotle*'s Expositors do note upon the 2. *de Anima, cap.* 1. that Life is taken two manner of waies: First for substantial Life, from which as a Fountain Vital actions proceed, which is in the Soul, which is the Root of al vital Powers and Actions, in which sence *Aristotle* himself takes Life, 2. *de Anima, text.* 37. when he writes, To live is the Essence of living things. Secondly, 'tis taken for the Vital Operation, or at least for the power of exercising those vital actions, whereof the foresaid substantial Life is the Principle; which being an accident, is by many called *Vita accidentaria*, accidentary Life. And therefore unless the Soul had life actually it could not communicate the same to living Creatures. Here indeed the Paradox-monger seeks an evasion to avoid this distinction by attributing this essential Life only to the Rational Soul, and the other accidentary to Bruit Beasts. But he brings no reason of this difference. Contrariwise, all the Expositors of *Aristotle* do attribute Life in both Sences to al Living things. And after the same manner, as there is in Man an Essential Life, from whence proceeds an accidental (for a Man hath not one Soul to make him a Man, and another to make him a Living thing) even so in Bruits also and Plants from the essential Life it self proceeds that accidentary Life. Yet there is this difference, That in Man by Death the accidental Life is abolished, the essential remaining; but in Beasts, both essential and accidental Life do perish. Which things were necessary to be said in this place for defence of the Truth.

whether there be nothing in a thing which was not in its Principles.

Life, how many wais taken.

Moreover, If Occult Qualities did flow from the Elements, there should be no other simple qualities in Nature besides those first of the Elements, but al should be tempers of the first, and so compounded, which is false. For the occult Qualities are perfectly simple, and arise from their simple forms; since those last forms are not barren and idle, but produce certain peculiar Qualities. For as from the simple form of Fire flows heat; so from the form

of

of the Load-ſtone flows the Faculty of drawing Iron, which is a ſimple Quality; from the Form in Rhubarb flows the Quality and Power of Purging Choler, which is a ſimple quality; and the ſame holds in al other Occult qualities. For the moſt good and great God hath not drawn al Forms out of the power of the Matter, but creared al things, and gave them their Forms; and thoſe not idle and ineffectual, and void of Forces, but endued with their peculiar Qualities, Proprieties, and Activities.

whether the occult Qualities flow from Heaven?

Some alſo there are who conceive theſe Qualities are infuſed from the Heavens. But ſince they cannot deny, That al Qualities and Proprieties do flow from their Forms, they are forced to grant that theſe Qualities alſo though they come from Heaven, yet it is not without the aſſiſtance of their Forms. But we have elſwhere proved, that the Forms come not from Heaven.

The true Original of Occult qualities. The differences of Occult qualities.

Al which Conceits therefore being falſe, it is moſt rightly determined and held, That as al other Faculties and Proprieties, ſo theſe alſo do flow from their Forms. But what thoſe Forms are we muſt now enquire. Which that we may do more readily and Eaſily, we muſt firſt ſhew the differences of theſe Qualities according to their Subjects, or of the ſubſtances to which they belong, whereby it wil appear that they have not al one Original. Bodies are ſome Living, others Lifeleſs; and of the Lifeleſs ſome have had life, as Rhubarb, Worm-wood; others neither have it, nor ever had. All which if they be diſtributed into their Ranks as they ought, ſix differences there will ariſe of Occult Qualities, in reference to their Original.

Occult qualities in certain ſorts of living things.

For in the firſt place there are certain hidden and wonderful Properties, which alwaies are found in ſome ſorts of living Creatures. An example of theſe we have in the Echeneis, Remora or Stop-ſhip, a Fiſh ſo called, whoſe ſtrange force (as others, ſo) *Pliny* admires in *lib. 32. cap. 1. Let winds blow* (ſaies he) *and the ſtorms rage, a very little Fiſh maſters their fury, and bridles all their ſtrength, forcing the Ships to ſtand ſtill in the Sea; which no Cables could do, no maſſie Anchors. It curbs the violence, and tames the rage of the wind without any pains to it ſelf, not by holding the Ship, nor by any other way than ſticking to the ſame. This little Creature is ſo powerful againſt all the ſtrength of wind and Tide, as to ſtop the Ships in their way. But Armed Fleets have Towers built upon them that they might fight in the Sea as from a City wall. Alas for the vanity of Man-kind! when a little Fiſh half a foot long can arreſt and hold in bondage their Men of War armed for the Fight with Braſs and Iron.* So far *Pliny*. And this is performed by the ſaid Fiſh only when it is alive. Alſo 'tis wel known what force the Torpedo hath, viz. How it does not only benum thoſe that touch it, but it ſtupefies the hands of Fiſher-men through the Net it ſelf. And ſome relate when it ſwims away alive, if a man ſtir the Water with his hand it nums his hand. And yet being dead the ſaid Fiſh is Food for ſome People. How admirable the forces of a live Baſilisk are may be ſeen in our *Epitomy of Natural Philoſophy*, Book 7. Chap. 10. yet being dead it may be handled without danger. Such Qualities are rightly derived from the Forms of Animals, concerning the Original whereof we have ſpoken elſwhere more largely, viz. how at the firſt Creation they were all created with Plants and Animals, and are now multiplied in the generation of Plants and living things, and have their Faculties implanted by the Creator.

Individual Properties

Secondly, There are ſome individual Proprieties in living Creatures. So ſome perſons cannot abide Cheeſe, this or that Fiſh, or other meat or drink; and Authors every where obſerve ſundry ſympathies and Antipathies of ſundry Creatures individual. Theſe Properties (ſince they are not common to the whol kind, but proper to ſome Individuals) do not ariſe from the ſpecifical form, nor do they belong to the Eſſential faculties which flow immediately from the Form, and like the Form it ſelf are immutable and incapable of degrees; ſuch as is in Man the Faculty of Reaſoning, Laughing, Seeing, Hearing, &c. But to Natural Powers and Impotencies they are to be referred, which flow from a peculiar diſpoſition of the Body, or its parts. Which diſpoſition ſince it is not eſſential to a Man, but variouſly mutable, a Natural Power, and a Natural Impotency, may be changed one into another: for examples ſake, It is the Property of a Man among other things, to deſire, digeſt, and be able to turn meats good for his Body into nouriſhment. But in that ſome cannot away with Cheeſe, others with a Pike-fiſh, others with Wine, that ſprings from a Natural Impotency ariſing from a peculiar diſpoſition of the ſtomach in this or that man: which being not alwaies perpetual (but ſometimes in progreſs of years, or for other cauſes it is changed) it many times fals out that he who in his Child-hood could not abide Cheeſe, nor to drink Wine, afterwards being grown up to mans eſtate he can away with both Wine and Cheeſe. Now whereas to Natural Impotencies do belong al thoſe things which belong to any ſickly conſti-

tution; those occult Qualities depend not upon distemper, or any Organink Disease, or of Solution of Unity, but upon an hidden an unexplicable dispositon. Indeed for a Man not to be able to desire to eat, nor to concoct his meat, may proceed from a manifest distemper of the stomach: but that he who can eat and digest al other meats, only should not endure Cheese, or Bread, or this or that sort of Flesh or Fish; this comes meerly from an Occult Quality. Now these dispositions are somtimes born with the party, and somtimes they happen afterwards. Of those which are born with the Party, some are Hereditary, which being before in the Parents, are derived into the Child with the Principles themselves of Generation: but others, though they were not in the Parents, yet are they imprinted on the Child by the imagination of the Mother; whence it comes to pass that Children cannot endure such meats as either their Mothers loathed when they were with Child, or which they longed for, and could not obtain. After Birth they are somtimes caused by loathing of some meat too often and too plentifully eaten. In which case the power of the Imagination commonly bears the greatest sway, of which I have treated in my Book of the *Consent and Dissent of the Chymists and Galenists, &c. chap.* 14.

Of the Occult Qualities of Jewels, Stones, & Metals.

The third kind of Occult Qualities is of things which do not live, but have nevertheless their specifick Forms, differing from the Forms of the Elements. So, by Reason of its Specifick Form the Load-stone draws Iron. And the several precious Stones, as also Metals and Minerals, have their Occult Properties and Faculties, which flow from their Specifick Forms; which Specifick Forms nevertheless (as al others) do lie concealed from the knowledg of Man.

Occult Qualities of dead things.

Fourthly, There are Occult Proprieties in Natural things which have formerly lived but now do not live any more. Such as are every where to be seen in Plants and Animals, which we use instead of Physick. For we use not ordinarily living Plants or Animals, but only such as are dead. So we use dried Toads to draw out Poyson: the ashes of River-crabs or Cray-fish cures the biting of a mad Dog: the Horns and Hoof of an Elk are good against the Falling-sickness: Harts-horn and the Bone taken out of an Harts Heart, are used against Poysons: Mans Skul cures the Falling-sickness: Rhubarb, Agarick, Mechoacan, white and black Hellebore, and other Plants, have a purging faculty: Peony Roots are good against the Falling-sickness: Scordium is good against Poyson: and there are very many more rare Vertues of Plants. And to this Tribe in a word belong the Vertues and Hidden Properties which are sought for in Plants and Animals after they are dead.

Whence they proceed.

Now certain it is, That these Occult Properties do not flow immediately from the Soul and Specifick Form of Animals or Plants; since the Soul is no longer in those Medicaments. Nor can they proceed from the Mixture of the Elements simply, and the temper of the first Qualities; since their actions are of a quite different kind from them, and above their activities, nor are they directed by the Soul, as being no longer present. And since every Quality pre-supposes a Form, these Qualities must also of necessity flow from, and depend on some Form. Now that can be no other than that which was before the subject of the more noble perfect and specifick Form, after its manner, and as far as belonged thereto. I say, after its manner, lest any should have occasion to quarrel. For that Form with its matter does not quite make up the ultimate subject, which is corrupted with the Form it self, or at least does not constitute a perfect Organ; since in Animals there is also required an influent Heat, and in Plants somwhat which holds proportion thereto. For seeing the more noble Form requires the more noble Matter, and as Forms differ in nobility or baseness, so also those matters differ, and are proper to several sorts and forms of things: the difference and diversity of those matters cannot come but from different Forms which constitute the proper subject of every Specifick Form. Which Forms (truly) considered by themselves are also true Forms, which do inform their Matters; but in respect of the Soul and Specifick Form they have the Nature of an immediate matter; and so one thing does not subsist by two substantial acts, but each hath one specifick Form. Now when the Specifick Form goes away, these Forms remain a while after, and perform the Office of Forms, and are the Authors of those Faculties which are found in many things after they are dead, but such as 'tis impossible they should proceed from the Qualities or Forms of the Elements.

Whence the subordinate Forms proceed.

Now what the Original of these Forms should be, is a Question hard enough, and few have enquired thereinto. And because I have spoke largely thereof in my *Institutions of Physick, Book* 5. *part* 1. *Sect.* 1. *ch.*2. I wil but briefly touch the same in this place. The most wise Creator, as he gave in the first Creation to al things their specifick Forms, so also he gave them different matters, to each a proper one, and in that matter also certain Forms proper

proper to every Species; and that for two intents: First that the ſpecifick Forms might have ſubjects wherein to be, ſubſiſt, and perform their actions. Secondly, That when the Soul or Specifick Form is gone, they might be uſeful to Man as Food or Phyſick. And as thoſe Specifick Forms are multiplied and propagated; ſo alſo theſe ſubordinate Forms are propagated. Or at leaſt (which I ſee is the Opinion of ſome others) the Souls of living things have an ability to produce ſuch Forms as are neceſſary to conſtitute their ſubject place or Manſion-houſe, which alſo may remain when they are gone. *The end of thoſe Forms.*

And foraſmuch as every Form requires its Subject and adequate Matter with which it is, and periſhes therewith, it is worth our Labor to enquire of the Subject of theſe Forms. Now this in Plants and Animals ſeems to be no other than that ſame implanted Spirit and Radical Moiſture which joyntly are called commonly Native Heat, and by late Writers (eſpecially Chymiſts) Natural Balſam. For Experience it ſelf teaches, That Plants and the parts of Animals, ſo long as they retain that Balſamick Subſtance, do preſerve their vertues entire: but as ſoon as they loſe the ſame, and become rotten or putrefied, they loſe alſo their vertues, ſo that the remaining Body becomes unprofitable. Which the Operations of Chymiſts and Apothecaries do ſhew. For if by boyling or ſteeping that part of the ſubſtance be ſeparated and extracted, wherein is the Purgative Faculty, an uſeful Medicament is made; and the remaining Body becomes quite ineffectual. *The ſubject of theſe forms.*

Fiftly, There are occult or hidden Qualities in ſuch things as are Naturally bred in Plants and Animals; ſuch as are the Poyſon of a Scorpion, an Aſp, an Adder, the Spider *Tarantula*, and other venemous Beaſts; Bezoar ſtone, Musk, Civet, Caſtoreum, and whatever other things there are of like kind Naturally bred in Animals. Hither are to be referred the juyces of Plants, their Tears and Gums, as Aloes, Scammony, Elaterium, Euphorbium, *Gambugia*, Opium, juyce of Hemlock, and many more of this kind. All which though they are to Men in place of Medicament or Poyſon, yet are they Natural and kindly to their reſpective Plants and Animals. Now al ſuch Qualities and their effects do not proceed immediately from the Soul or Specifick Form of thoſe living things, but from their own proper Form; ſince being ſeparated from the living things, they have nevertheleſs their effects and operations. Now whence theſe Forms proceed, though it is not very eaſie to declare; yet it ſeems moſt ſafe to hold, That thoſe things receive the ſaid Forms from their own Souls, and that thoſe Forms are ſome way included in the Souls, or at leaſt proceed from them. For as the ſoul hath a power to make Chyle, to make bones, and to make skin; even ſo other Juyces are produced in other living things, as Oyl in the Olive Tree, Wine in the Vine; and after the ſame manner thoſe Medicinal and venemous juyces aforeſaid are produced by the Soul proper to their reſpective kind. And as Wine though no longer animated with the Soul of the Vine, yet retains many yeers that ſame form which it received from the Vine as a Body Natural; ſo the juyces lately mentioned do long retain their Forms and Vertues entire; yea, and they have ſome affinity to, and correſpondence (as it were) with the forms of that kind, and perform motions anſwerable to their motions. Whence it is that Wine in the Hogshead is wont to work when the Vines do bloſſom. For the reaſon of all ſuch things lies concealed in the ſeed; becauſe (as *Ariſtotle*, 5. *de Gen. anim. cap.* 7. ſaies) Principles of things though ſmal in Bulk, yet are exceeding great in faculty and power, which is eſpecially true of the ſeed; and what *Seneca* ſaid excellently, *Lib.* 3. *quæſt. nat. cap.* 29. concerning Man, is true of al other living things. In the ſeed (ſaies he) *is contained all the Nature of the future man; the Infant not born hath in it the Principles of a beard, and of Gray Hairs.* *Occult qualities in things which are naturally bred in Plants & Animals.*

In the ſixt place, are malignant Humors and Poyſons, which are preternaturally bred in the bodies of Animals, and do al operate by hidden Qualities. Such are thoſe Humors whence the Falling-ſickneſs, Mother-fits, Malignant Dyſenteries, Malignant and peſtilential Feavers, yea, the Plague it ſelf, the Scurvy, the Leproſie, are generated; alſo the poyſon of a Mad Dog. Of the Generation whereof we have treated in our *ſixt Book of Practice, part the ſecond.* *Occult qualities of things preternaturally bred in the Bodies of Animals.*

Chap. 4. *Of the Difference of Occult Qualities.*

NOw Occult Qualities are not of one kind, and the firſt difference appears from what hath been ſaid in the foregoing Chapter, by which it is manifeſt that there are ſix kinds of them in reference to their Original, touching which 'tis needleſs to add any more. *The differences of occult qualities.*

In the ſecond place, There is another difference drawn from the manner of inhering. Vulgarly, as alſo it appears from *Scaliger*, *Exercit.* 71. they ſay ſome Qualities are real, others

others intentional. The greenness on the Tree they say is a real Quality, the greenness cast by the Tree upon a wall, or on a mans cloaths, is an intentional Quality: the color of a Glass of Claret is a real Quality, the redness thereby caused upon the Table-cloath is an intentional quality, the light shining through the Glass of Wine. Where the thing it self is truly declared, but the names are not convenient. For since that is properly termed intentional which depends upon the operation of our mind, and is nothing without the same: after this manner these Occult Qualities cannot be termed intentional, nor are rightly opposed to real Qualities, since they themselves are also real, and are found in Nature when we think not of them, and have real effects. I conceive the color in the Tree, and the Wine in the Glass should be more rightly called material qualities, seeing they are not separated from the Matter; but the other Spiritual Species or representations. And there is no smal difference betwixt those material qualities, and these Spiritual Species. For the former are in their Subject, and are moved with it, and according to its motion, nor are separable therefrom, and are successively received in their Subject, nor are they divers differing in number in the same Subject, not confused but distinct. But those Spiritual Species are diffused from the Body whence they arise round about in a right line like Raies, nor are moved with the air wherein they are; in the same Subject they are many in number, not confused, as appears by the sundry shadows made by several Candles; also many of them pass through solid Bodies, as appears by sounds, and the vertue of the Load-stone. Nor are they ineffectual, but have in them the vertues of those things from which they flow; as Shine represents the Light; the Load-stone draws Iron, the shadow of the Eugh-tree is hurtful. And although these Species are commonly reckoned only amongst Sensible Species; yet doubtless there are many more of them than are discerned by Humane Senses. And by means of them many Sympathies and Antipathies of things do happen, and wonderful actions and operations, which are by some termed Magnetical. Which very thing *Jul. Cæs. Scaliger* acknowledgeth, who in *Exercit.* 344. *Sect.* 5. where he speaks of Sympathy, at last concludes, That such things are done by Species, and that those Species are like a continual Ray promoted, which is propagated through and beyond the Body of the Glass.

Material Qualities and spiritual species, how they differ.

What spiritual species are.

But what these Spiritual Species are is not easie to say. They are commonly called Qualities; but this term likes not *Fracastorius*, *Lib. de Sympath. & Antip. cap.* 5. who holds that they are Substances, and of the same nature with those Forms whose Species they are, not differing from them save in their manner of subsisting. For so far he saies they are Material, because they are in the matter by a certain gross existence, and require certain limits. And since it is the innate property of al Forms to propagate themselves, and these material Forms cannot propagate themselves after their own manner of existence, they produce a thin and Superficial part or degree of themselves, which they term *Epipole*, which by reason of its tenuity both hath no contrary, and is bred and propagated in a moment, as a kind of Brood. But hardly wil any man say, That the Light and Shine of the Sun are of the same Essence one with another, much less that they are of the same Nature with the Suns Form; or the color in a thing with that in its Image in a Looking-glass. But how (in case they are Qualities) they should be generated in a moment and propagated, not moved with the Air through which they are diffused, and that divers in number of the same sort should be in the same Air unconfounded or jumbled together, there is hardly any man can well tell.

For the same obscurity we meet with in the sensible Species of Nature, we find also in all other her Spiritual Species, which are many more than can be discerned by our Senses, or is commonly believed.

Occult material Qualities.

According to this Difference of Qualities Occult Qualities also differ. For first there are Occult Qualities which may be termed Material because they are alwaies propagated with the Matter and Subject wherein they are generated, and do not diffuse themselves without the same. And though they may seem to diffuse themselves into other bodies, and afar off; yet that is done by Atomes and their smallest Corporeal Particles, which differ from the Bodies from whence they flow only in Magnitude, and have the same Essence, Qualities, and Faculties with them. Such are al those Occult Qualities by which contagious Diseases are conveighed into other persons, as is seen in the Venereal Disease, the Leprosie, Pestilential and Contagious Feavers, and the Plague it self. For in al such Diseases certain very smal particles flow from the sick body, which being received by other bodies they raise in them the same Disease; as I have shewed at large in the *Second of my Institutions, part* 2. *cap.* 12. and my *Fourth Book of Feavers, Chap.* 3. and my *Sixt Book of Practice, p.* 3. *cap.* 3.

cap. 3. For these are not Species carried right on as a Ray, but little Particles or smal Bodies which are themselves disorderly moved by the motion of the Air: nor is any man infected either with the Plague, Venereal Pox, or Leprosie, unless he receive into his Body some of those foresaid Particles or smal Bodies.

Spiritual Qualities.

Again, There are Occult Qualities which are justly termed spiritual Species, because they pass from their Body like a Ray continually thrust forward, being circularly diffused, and have a certain Sphere of their activity, and some of them do also pierce through other Bodies. So a Load-stone draws Iron though a Board be betwixt them: a Cat shut up in a chest can affect a Man that hath an Antipathy against Cats; the Dog through the shut door by vertue of these Qualities knows his Master to be there; the *Torpedo* benums the Fishermans hand through the staff of an Eel-spear. And *Avicenna* and the Conciliator in *Lib.* 1. *de Venen. cap.* 1. speak of a Serpent who infected and killed a Soldier through a Spear, with the end whereof he touched it. So the Basilisk or Cockatrice kils a Man by looking on him. Which things the foresaid Qualities adhering in the matter cannot do. Nor can a Man sick of a contagious Disease infect another through the door (being shut) since those smal bodies cannot pierce the boards.

The third difference of Occult qualities.

Thirdly, There is yet another Difference of Occult Qualities observed as yet by very few, viz. There are some Spiritual Qualities which flow from other things, are received in some Bodies, and being received in them they have the same Faculty as the others. Such a like thing is observed in the Load-stone. For the Vertue thereof is received by Iron, whereupon the Iron also gains the faculty of drawing Iron, and moving to the Poles. Nor is this only done by rubbing upon the Load-stone, and the communication of certain Atomes; seeing Iron shut up and covered wil receive vertue from the Load-stone, which I my self have observed. For having once an Ivory-cover'd Sun-Dial made with a touched Needle, in the same case of box with a greater Load-stone, the Needle of the Sun-dial quite changed its faculty of turning to the Poles, and was moved with a new kind of motion. So Dogs follow their Masters, and they hunt the Beasts by the track of their feet, such species being doubtless printed upon the Earth and Grass which they perceive by their smelling faculty. For it must needs be some real thing that works upon their Smel, and yet not a material quality, which with its smal bodies hath no fixed mansion, but is inordinately moved with the motion of the Air. And I am confirmed in my Opinion by *Nicolas Cabeus*, in *Lib.* 3. of his *Magnetick Philosophy, cap.* 21. where he informs us, That Iron attains its verticity or a faculty of turning towards the Poles, not only by touching the Load-stone, but by being near the same also. Take (saies he) a Needle which hath never touched a Load-stone, and hang it up by a thred, then hold it towards the Load-stone, but so that it may move towards the Load-stone, but not touch the same, nay, that it may be a pretty distance therefrom; I say, it will so come to pass, that the Needle shal receive vertue from the Load-stone not only by touching it, but also by approaching the same without touching: yea, it would derive into it self the vertue of the Load-stone, although some other Body were interposed betwixt the Needle and the Load-stone, as Wood, Stone, or any other. This appears first by experience. For if (as I said) the Needle be hung up so far off, that it aspires indeed to touch the Load-stone, but cannot do it, either because it is held afar off, or because some other Body is interposed betwixt it and the Load-stone; If afterward you take away the Load-stone the hanging Needle wil shew al the magnetical Effects most clearly, which before it did not shew, even as if it had touched the Load-stone. For ballanced it will turn to the Poles, its point looking alwaies to the North, according to the magnetick Laws, and it wil draw filed Iron; so that try it which way you will, it wil continually most clearly evidence its magnetick Vertue, which did not appear before it had so made its approaches to the Load-stone. Therefore the Load-stone conveighs its Verticity and Vertue into the Iron not only by touching the same, but by its presence alone if it come but near the same. Moreover, this is also apparent by Reason. For the Loadstone hath not only in it self a Magnetical Vertue, and consequently a Faculty in it self to produce the same in Bodies having affinity thereto, but it also sheds forth round about the said Vertue, and forms to it self a Sphere of activity. And many other such like Species there are (doubtless) which pierce as easily through the most solid Bodies, as through the thinnest Air. So far *Cabeus*.

Now such Qualities are received in any Body agreeable thereto. So the magnetick Quality is received in the most pure Iron. Also the same *Cabeus* writes, it is received in those Bricks which through vehement burning have gained the color of Iron, and are therefore either from their color or hardness called Iron Bricks. *Lib.* 2. *Philosoph. Magnet.*

Magnet. Cap. 8. and if you take a bit of such a Brick, and touch it artificially upon a strong Load-stone, it receives (he saies) the Quality of turning to the two Poles of the World.

The fourth Difference. Fourthly, Occult Qualities are also distinguished in respect to their effects, in regard some cause Sympathy, others Antipathy, examples whereof are every where to be seen in Nature, and they are collected by *Fracastorius* in his Book *de Sympathia & Antip.* Marcellus Donatus, *de Histor. Med. mirabil.* Johan. Francisc. Ulmus, *de Occult. in art. med. proprietat.* Andreus Libavius, *part* 2. *singul. tr.* 4. Johannes Schenckius, *Lib.* 7. *Observ. in fine.* which I think needless to repeat in this place.

The fift difference. Fiftly, There is a certain difference which *Galen* reckons up, 6. *Epidem. com.* 6. *text.* 6. where he divides things which work by Propriety of their whol substance into four kinds; Aliments, Medicaments, Poysons, and Antidotes, wherein are comprehended al things in Nature, Minerals, Stones, Plants, Living things. And as to Aliments or Foods, of necessity some likeness there must be and sympathy between the Food and that which is nourished thereby; which consists not only in the first Qualities, and their Temperament, but also in the whol substance and occult qualities; which even hereby appears, in that there is not one Aliment of al living things, but sundry Aliments. For several Plants growing in the same Field do each draw its own proper Aliment, and as *Hippocrates* writes, *Things that grow and are sown, when they come into the ground, each draws that which it finds in the Earth suitable to its Nature. Now that is sowr, and bitter, and sweet, and salt, and all kinds of Juyces.* And the same holds in Animals. For such things as are poyson to a Man are food to some Creatures; as Hellebore to the Quail, Hemlock to the Starling, Frogs, Snakes, Toads to the Storks. Yea, and some men delight in some kinds of Meats, and abhor other some.

Occult quality of Aliments.

The quality of occult Medicaments. Now it is a thing not to be doubted that most of the Vertues of Medicaments proceed from occult Qualities. Purgatives exercise their Operations by occult Qualities. And so do specifical Medicaments, and those which are proper to several parts of the Body; also Amulets, and al things that help or hurt the Body, externally applied. Hitherto pertain Smels, Fumigations, and those hidden steams which work upon Man and Beast; as it is very wel known how Dogs follow their Masters and wild beasts footing by the scent; and some cannot endure a Cat in the room though they see it not, as was said before: not to speak now of such things as mutually work one upon another by seeing and hearing. Of al which *Johannes Francisc. Ulmus* brings many examples in his whol Third Book *de Occult. in arte Medica Proprietat.*

The Occult qualities of Venoms. And touching Poysons, it is so manifest that they act by occult Qualities, that *Julius Cæsar Scaliger* writes wel in *Exercit.* 218. *Sect.* 8. If nothing else could perswade us how vainly and rashly many endeavor to reduce al things to manifest Qualities, at least poysons and their Remedies might teach us so much.

Of Antidotes. And the same may be said of Antidotes, seeing they are opposed to Poysons, and therefore as Poysons are hurtful to our body, not by manifest, but by Hidden Qualities; so are these also contrary to Poysons, not by manifest, but by Hidden Qualities.

And whoever shal observe what hath been here said in general of Occult Qualities, he may with little difficulty understand such things as he shal meet with in the Writings of Natural Philosophers and Physitians concerning the said Qualities.

THE

a Pouder: give hereof a dram at once, with the Syrup of Sorrel.

Some there be likewise that commend the Water of Nuts.

They commonly administer one dram of *Sperma Ceti* dissolved in Vinegar, or some fit and convenient Water.

There are likewise some that make use of Unguents, and that with good success also; which are likewise taken into the Body, and are therefore stiled Potable; as for instance, the Potable red Unguent of the *Ausburg* Practitioners. Or,

Take *Green Sanicle four ounces*; *the Leaves of Betony, Fennel seed, Juniper Berries unripe, of each three ounces*; *the Root of Elecampane, of the greater Comfrey, Rue, Ground Ivy, Rosemary, Rhapontick root, of each two ounces*: *all these being shred very smal, let them be stirred about and incorporated with three pound of fresh Butter*: *Set them then in the Sun for eight daies: afterward put thereinto one Cyath or little Cup ful (about two ounces) of Sanicle Water*; *then boyl it til the water and juyces be quite consumed*; *and then let the Butter thus incorporated and moistened with the Juyces be pressed forth, and kept for use.* The Dose is half an ounce twice a day, to be taken with warm Beer; the place affected may likewise be outwardly anointed with the same, yet not at the first beginning and appearance of the distemper, but some while after. Or,

Take these Herbs, *Wormwood, Southernwood, of each two handfuls*: *the Herb Ladies Mantle, Motherwort or Mugwort, the lesser Comfrey, the lesser Sage, Germander, the lesser Centaury, Crosswort, Fennel, Strawberries, Fenugreek, Ground Ivy or Alehoof, Hyssop, Lavender, Milfoyl, Marjoram, Balm, Bugle, Pennyroyal, Pyrole or Winter green, Pimpernel, Rosemary, Sage, Sanicle, Savory, Spicknard, Betony, Vervain, of each one handful*; *the roots of Marsh-mallows, Clove-gilliflowers, the greater Consound, Angelica, Pimpernel, and Tormentil, of each of these one ounce.* These Herbs and Roots gathered green in the month of *May* or *June*, boyl in six pound of *May Butter*; adding thereto as much *Wine* as you judg sufficient: let them boyl together, until they be boyled enough, stil taking heed that they burn not to; and in the end adding of the Oyl of Bayes fresh and new, four ounces; *Sperma Ceti* half a pound; Make herewith an Unguent of a green color: the Dose is one ounce, in Vinegar or Beer; and this may likewise be outwardly applied unto Wounds. Or,

Take *the Roots of Tormentil, Dittany, Sanicle, the greater Consound, Consound Sarracen, of each two ounces*; *Castoreum one ounce* (that sort of it that is offensive by reason of its unpleasing tast may be omitted) *Madder three ounces*; *May Butter three pound*; *red Wine as much as will suffice*: *mingle and boyl them till the Wine be consumed*; *herewith make an Unguent*; *adding thereto of Sperma Ceti one ounce.*

As for the Topicks, at the first beginning some Astringents are to be mingled with the discussive Medicaments. For when the Tunicles of the Veins (out of which the blood is poured forth) are somwhat bruised, they ought then to be a little strained together, bound fast, and condensed, lest that the new matter drawn thither by pain be poured forth; since that if in the beginning only Digestives be administred, they wil not only discuss the blood poured forth of the Veins, but attract and draw unto the part that blood that is in the bruised smal Veins. Afterward, that the little contused or bruised Veins may return unto their Natural state, Digestives alone are to be made use of. For this end and purpose, some there be (now this indeed is the best kind of Remedy especially for those that are beaten) that wrap about the sick person the Skin of a Ram new flaid off, and whilst it is yet hot, besprinkled with Salt, Myrtle Berries, and the Pouder of Water-Cresses; or if such a skin may not conveniently be gotten, they anoint the Patient with the Oyl of Roses, of Myrtles, and of Earthworms, with which they mingle the Pouder of red Roses, or Myrtle Berries; and the day following such a like Liniment may be administred;

Take *Unguent Dialthæa three ounces*; *Oyl of Earthworms, Camomil, and Dill, of each one ounce*; *Turpentine two ounces*; *the meal of Fenugreek, the pouder of red Roses, and Myrtles, of each half an ounce*; *Saffron one scruple*: *make a Liniment, or an Unguent with a sufficient quantity of Wax.*

If there be any particular Contusion, such a like Liniment may at the first be administred;

Take *Oyl of Roses, of Myrtles, of Camomil, of each one ounce*; *the white of one Egg*; *the pouder of Myrtles and Roses, of each two drams*: *mingle, &c.*

After this, on the third day, let the part affected be fomented with the Decoction of Camomile, Wormwood, and Cummin.

The next following Liniment may likewise be administred. But now in the curing of the Suggillation the most efficacious Remedy is the Root of the Herb *Sigillum Solomonis*, or Solomons Seal; which either new gathered, or else in the Winter season macerated in Wine, and bruised, and then applied in the form of a Cataplasm oftentimes in one only night wholly taketh away the Suggillation, so that the Native heat returneth unto the part affected. Or,

Take *the Roots of both the Consounds, of each three ounces*; *Camomil and Melilot flowers, of each two smal handfuls*; *the meal of Barley, Fenugreek, and Beans, of each one ounce*; *the pouder of Wormwood, half an ounce*; *Cummin seed one dram*; *Saffron half a scruple*:

Mingle them, and make a Decoction for a Cataplasm.

There is likewise commended a musty or mouldy Nut bruised, Reddish Seed, with dried Figgs; Mustard Seed with Vinegar, Rue with Honey. Or,

Take *the Root of Wake-Robin or Cuckowpint while it is green, an ounce and half; Solomons Seal four ounces; these Roots being shred smal, pour upon them the water of Elder flowers, white Lillies, and Bean flowers, of each four ounces, Wine Vinegar two ounces, Alom six drams, one Gall of a Bull; let them stand and digest for the space of eight daies, and every day during that time let them be well shaken together.*

In this Water let Linen Cloaths be well soaked, and so applied unto the part affected. Or,

Take *Pigeons Blood, Cummin, Camomile, of each one dram; the meal of Fenugreek, half a dram; Celtick Spikenard one scruple, Malmsey as much as is sufficient; make a Liniment.*

In special, in a Swelling (especially if there be a Leaden and wan colour after Venesection) there may be fitly applied the Oyl of Rue, and the Leaves of common Rue, boyled in common Oyl imposed upon the place affected.

But if the Malady be not remedied by these medicaments, neither the blood that is shed forth without the Vessels may by them be dispersed, then if the place wil bear it, Cupping-glasses are to be administred; which are the most effectual Remedy for the extracting of whatsoever is conteined in a deep place; and moreover if need require, Scarifications are also to be made use of, that some of the Blood may manifestly be evacuated and emptied forth.

But now if by all these there cannot be made that Resolution of the Blood that ought to be, and withal if there be present any tokens and signs of a suppuration, as for example, if the place swel up a little and appear soft to the touch; if there be a certain beating pain, and a redness begin to appear round about, then the suppuration (in the common and received Opinion and Judgment of Chirurgeons) is to be holpen on and by all means to be furthered. The Suppuration being thus finished and wrought, the Ulcer is then to be purged and cleansed, filled up with Flesh, and at length closed up with a Cicatrice. Yet notwithstanding in the use of these suppuratives great caution is to be had; and of these only such as are gentle, mild, and moderate, are to be administred. For if there be any error committed in the use of these, and that we be not extraordinary carefull in this point, there may easily be excited in the part a sordid and filthy Ulcer, and a putridness withal. When therfore some of the latter Chirurgeons & those of our time wel consider the Premises, and what we have said, they advise, that when we perceive that the Contusion is converted and turn'd into an Impostume, a perfect suppuration is not then to be expected. For if the *Pus* or purulent matter that is generated from the congealed and clotted blood be any long time detained and kept in the place affected, it may then excite and cause many evils, as Feavers, pains, and an extraordinary putridness; and may likewise corrupt the neer neighboring parts, the Nerves, and the Bones; whereupon afterward Ulcers of dangerous consequence, and Fistulaes also even from hence oftentimes take their Original. Neither likewise do these admit of any Emollient and suppurating Emplasters and Cataplasms; in regard that by these a putridness, and those other evils and mischiefs that are wont from thence to arise, may easily be excited in the part. But they counsel and advise us rather that such a place wherein there is contained any clotted blood (which now exciteth the Apostem) be forthwith opened with a Pen-knife; and that in the Wound made by Incision there be conveyed in a Tent anointed with Unguent Ægyptiack; and that the whol place be wel fenced and covered with some fit and convenient Emplaster that may preserve the Native heat thereof, and defend it from putridness. And this they conceive is more especially to be observed, if the contusion be made in the Sides, the Belly, or the Back. For then there is diligent heed to be taken, whether or no on the third, fourth, or fifth day (in that place wherein the Contusion or bruising happened) there arise any Swelling with a pain, and thenceforth from day to day encrease; and whether or no there be a beating pain excited; and that the sick Person cannot wel endure that the said place be touched; and whether there be another kind of redness appearing in the Circumference; and whether the breathing be difficult; and some kind of preternatural heat discovering it self in the Body. For wherever these things appear, (albeit there be appearing no wanness or Leaden colour in the external parts) it is a sign and token that the *Pus* or corrupt filth is gotten together, and that the Impostume is excited. Whereupon (left that the *Pus* convert it self unto the more inward parts, and there raise as it were Conny-burrows (for so they term them) and gnawing asunder eat through the more inward parts, and so by this means hasten upon the sick Party a sudden Death, or long continuing Diseases, the the place is speedily to be opened; for the place being thus opened, the *Pus* very easily issueth forth. Let the Wound be afterward handled and ordered as we said before; and herein we must not neglect or omit Venesection, and Vulnerary Potions; but they conceive that there is scarcely any, or at least very little benefit arising and accrewing to the Patient from Emollients and Suppuratives.

But

But if the Contuſion be great, or that any error hath been committed in the Cure, or that the place begin to look black and blewiſh, and to be mortified (by reaſon of the ſuffocation of the Native heat, ſo that a Gangrene and Mortification be feared, as like to enſue) then in the firſt place Scarification is to be adminiſtred; or likewiſe, if need ſo require, Cupping-glaſſes are to be applied, that ſo the corrupt blood may be evacuated. After this the part is to be fomented with warm Vinegar, or the Decoction made of the Reddiſh Root, of *Serpentaria* or Vipers Graſs, Cuckowpint, Solomons Seal, and Wine as much as will ſuffice. For ſuch like Remedies diſſolve the clotted blood, and draw it forth from the very bottom unto the outmoſt part of the Skin. And after let there be applied the Diachylon-Flower-de-luce Emplaſter. Or,

Take *Southernwood, Cumin Seed, Camomile Flowers, of each one dram; the Juyce of Wake-robbin or Cuckowpint as much as will ſuffice; make hereof a Cataplaſm.* Or,

Take *Oyl an ounce and half, Wax an ounce, the Juyce of Marjoram an ounce and half; let them diſſolve together at the Fire, and then add of the Spirit of Wine one ounce.*

And to conclude, that which *Paræus* adviſeth is to be taken notice of; to wit, that in the contuſion of the Muſcles (and eſpecially thoſe about the Ribs) the Fleſh a little ſwelleth up, and becometh as it were ſnotty and purulent; inſomuch that if it be preſſed down and ſqueezed together it ſendeth forth a flatulent Air, with a certain kind of low noyſe and gentle hiſſing, and withall the print and impreſſion of the Fingers remaineth, and is to be ſeen for ſome while after. And thereupon (in that void ſpace that the Fleſh ſeparating it ſelf from the Bones hath left) there is a purulent and rotten filth gathered together, by which there is cauſed a ſyderation and putrefaction. If therfore this ſhal happen, the Malady is ſpeedily to be taken in hand, the beſt means uſed, and the part moſt ſtrictly and cloſely to be drawn together; and furthermore, *Oxycroceum* or *Ireat Diachylon*, or the like Digeſtives are to be adminiſtred.

And thus much ſhall ſuffice to have been ſpoken touching Tumors ariſing from the Blood; there now follow thoſe Tumors that ariſe and proceed from Choler.

Chap. 17. *Of the Tumor* Herpes.

HAving hitherto treated of and explained the Tumors ariſing from the blood; it now remaineth in the next place, that we likewiſe explain and declare thoſe Tumors that proceed from Choler. Among the which the *Eryſipelas* is commonly wont to be firſt propounded and reckoned up. But ſince that, as we conceive, the *Eryſipelas* (as it is now adaies with us) or as it hath been by the Ancients vulgarly termed, *Roſa*, may more fitly be recounted among the Tumors ariſing from the blood; we have therefore treated thereof above, among the Tumors proceeding from blood, in the ſeventh Chapter; where we handle the *Eryſipelas*.

But now *Herpes* is truly and properly a Tumor proceeding and taking its original from Choler. And it is termed *Herpes* from its creeping; to wit, becauſe it ſeemeth to creep like unto a Snake; and for this reaſon, becauſe that no ſooner doth one part ſeem to be healed and wel, but the Diſeaſe inſtantly creepeth unto the next adjoyning parts. And although (to ſpeak truly) there are very many Maladies that Creep along; yet in ſpecial, that Tumor is by Phyſitians termed *Herpes* that is excited in the ſuperficies of any part (from yellow choler ſincere or ſimple, that is, ſevered from all other humors) and from thence creepeth along unto the parts next adjoyning. For as the *Eryſipelas* ariſeth from blood very thin and cholerick; ſo the *Herpes* proceedeth from excrementitious Choler. *Celſus* ſeemeth to propound and mention *Herpes* under the name and notion of *Ignis Sacer*, or the Sacred Fire: whereas other Latine Phyſitians underſtand an *Eryſipelas* under this appellation of *Ignis Sacer*.

The Cauſes.

The conteining Cauſe of *Herpes* being ſincere, pure, and ſharp Choler, ſevered and ſeparated from the reſt of the humors; which by its implanted thinneſs penetrateth and pierceth even unto the outward or Scarf-skin, and is by and through it diffuſed; it hence appeareth and by conſequence followeth that the Tumor or ſwelling in it is yet leſs than in an *Eryſipelas*. For as in an *Eryſipelas* the Swelling is leſs than in a *Phlegmone* by reaſon of the ſmal ſtore and thinneſs of the matter that is found in the one more, in the other leſs: ſo again in the *Herpes*, the ſwelling is leſs than in the *Eryſipelas*, for the very ſame cauſe. But as for the Antecedent and Procatartick Cauſes, they are almoſt the very ſame, as in an *Eryſipelas*; yet notwithſtanding ſomwhat more diſpoſed to the generating of an excrementitious yellow choler, then to the breeding of a cholerick Blood.

The Differences.

The Differences of *Herpes* are taken from the diverſity of the conteining Cauſe, and the humor: For although every *Herpes* hath its original from Choler and a thin humor; yet notwithſtanding, ſince there are certain degrees of its tenuity, thinneſs and purity; if that humor, or choler, be ſimple and of a thin ſubſtance, then the Affect that reteineth the general name is termed a ſimple or ſingle *Herpes*. But then if there be any portion of Flegm mingled therewith, there is produced an *Herpes* that cauſeth and raiſeth little Bladders in the Skin like unto the Miller, whereupon it is called *Herpes Miliaris*. And laſtly, if the Choler

be more sharp and biting, so that it eat through the skin unto which it adhereth, it is then termed *Herpes Esthiomenos*, that is, the eating *Herpes*; and this same by *Galen* (in his 14. Book of the Method of Physick, Chap. 17.) is called absolutely and only *Herpes*, and is almost of the same nature with an exulcerated *Erysipelas*; from which notwithstanding it differeth in the thinness of the humor. For so saith *Galen* in the place before alleadged: *It is* (saith he) *an exceeding thin humor that exciteth the* Herpes; *even so thin, that it doth not only pass through all the interior parts, which likewise are of a fleshy substance, but also the very Skin it self, even unto the utmost part of the Scarf-skin, the which alone (in regard that it is kept in and reteined by it) it both gnaweth, and likewise eateth through; whenas if it could also in like manner pass through it by sweating, it would not then excite and produce any Ulcer.* But now the exulcerated *Erysipelas* and the *Herpes Esthiomenos* differ likewise in this regard, that the exulcerated *Erysipelas* doth not only seiz upon the Skin, but also upon some part of the Flesh that is underneath it; but the *Herpes* exulcerateth only the Skin.

Signs Diagnostick.

In regard that the *Herpes* is apparent and manifest unto the Senses, it is therefore easily known. For it is a broad Tumor that hath little or no heighth in it; so that the part is scarcely lifted up at al; but may seem rather to be exasperated, then to swel up unto any heighth. There is moreover present to accompany it a certain kind of hardness, and a pain, and as it were a certain sense and feeling of an heat and burning. But the *Herpes Miliaris* hath divers smal Pustules like unto Millet, in the very top and outside of the Skin; of the which although some one or more of them be cured, yet notwithstanding there wil be still others arising; so that the Malady may seem by creeping still to move forward unto the adjacent parts: and if the Pustules be broken there will something that is of a quality and resemblance betwixt *Pus* and rotten dregs flow forth, the place it self will be very red; and oftentimes also it will have a middle colour, neither absolutely red, or pale, but between both. But then the *Herpes Esthiomenos* (or the *Herpes* that eateth through) is, when there appear many smal creeping Ulcers, and holes, which yet notwithstanding proceed not beyond the Skin; or, as *Celsus* (in his fifth Book Chap. 26.) writeth, *It is a Malady with an excoriation and exulceration of the highest and utmost Skin, without any heighth at all, broad, somwhat pale and wan, yet unequally, the middle whereof becometh whol and sound, when at the same time the extream parts thereof are in their progress and motion forward; and oftentimes that which seemed to be altogether whole and sound is again exulcerated; and the Skin that is next about it (which the Malady is even now ready to seiz upon) is somewhat more swoln and harder, and hath a Colour changing from Red to that which is dark and blackish.*

But, that we may likewise here give you to understand this, the more modern and late Physitians (whom we commonly stile Barbarous) almost all of them comprehend the *Herpes Miliaris* and the eating *Herpes* under the name of *Formica*, as being deceived either by the likeness of names, or else by Ignorance; whereas notwithstanding with the Grecians *Murmecia*, that is, *Formica*, is a certain kind of Warts.

Prognosticks.

1. The *Herpes* (albeit there be no danger in it, unless it be greatly exulcerated, and extreamly putrid) yet notwithstanding it is not easily cured; and usually the Disease is of a long continuance, unless there be (in the Cure) a due regard had unto the whol body.

2. Accordingly as the Choler from which the *Herpes* ariseth is more or less peccant and offensive, so likewise is the *Herpes* to be accounted more or less dangerous.

The Cure.

That so therfore the *Herpes* may be cured, there ought to be a due regard had unto the Cause Antecedent, and Continent, as also unto the part affected; and in the first place, and especially of the Antecedent. Since therefore that *Herpes* hath its original from yellow Choler and a salt humor, the said yellow Choler is first especially to be purged out of the Body; for unless the Body be purged, the sick Person wil never perfectly be cured and made sound. For although upon the applying of Topical Medicaments, in some one place the part may seem to be sound and wel; yet notwithstanding it soon breaketh forth again in another. If the matter be extraordinary thin (as it is evermore in *Herpes*) then Sudorificks ought likewise to have their due and proper place. But if there be any thing of Phlegm, or of the serous wheyish humor therewithall mingled, then some of those Medicaments that purge Flegm and Whey may therewith be mingled. The Diet likewise that is prescribed ought to be such as is fit and convenient where Choler and the adust humor offendeth.

Now when we have in the first place done what is requisite as to the Antecedent Cause, we are in the next place to take into consideration that very Cause that we call conteining. And therefore first of all, when there is in the Skin an extream and intense heat of Choler, then Coolers are to be administred, that may both extinguish the fervent heat of the Choler, and likewise repell and drive back moderately; such as are those Refrigerating Medicaments that are commonly wont to be administred in the *Erysipelas*; as for instance, Let-

tice,

tice, Knotgrass, and Navel-wort (which last some cal *Venus*-Navel, or Kidney-wort) and the like. After that the fervency of the heat is somwhat abated and qualified, that which remaineth behind is to be digested and dissipated by Medicaments that are rather of a drying Nature than such as moisten: as for example, Linseed boyled in Wine and Oyl, and the spume or froth of Silver. And these are more convenient in a simple heat. But now if Pustules shal chance to happen, because that they are somtimes broken and putrefie, (lest that there be excited in the part a putridness) those Refrigerating and Repelling Medicaments ought not to be cold and waterish, but cold and dry. And therefore in the first place, we are to make use of the yong Shoots of the Vines, the tops of the Black-berry bush (or as some cal it the Dog-berry tree) the Leaves of the Sallow tree, and Plantane. Here is likewise useful the Cataplasm that is made of the Rinds of the Pomegranate, and Barley meal boyled in Wine. There may also be administred, Galls, Cypress Nuts, Pomegranate flowers, Bole-armenick, and Terra Sigillata. And when at length there is need of Digestives, there may be Cataplasms compounded of the Meal of Miller, Beans, Flax, and Lupines, boyled in Wine. If the Pustules break, and the *Pus* flow forth, there are likewise Cleansers to be administred. For this end and purpose, this following is fit and proper:

Take *Plantane, Shepherds Pouch, the tops of the Bramble bush, of each one handful; the cups of green Acorns twelve pair; Myrtle leaves one ounce; Pomegranate flowers, Myrrh, and Frankincense, of each half an ounce; boyl them in Water out of the Smiths Forge.* Or,

Take *Rosin, Turpentine washed with Rose water, of each one ounce; Oyl of Roses half an ounce; the Yelks of two Eggs, the juyce of two sweet Oranges: Mingle them, &c.*

In the *Herpes Miliaris* this is likewise very useful:

Take *Chalk, Oyl of Olives, and Vinegar, of each as much as will suffice: Mingle them and make a* Liniment.

Valescus de Taranta, in a proper and peculiar Chapter of the cure of *Formica,* commendeth for a secret this that followeth:

Take *the moist juycy Wool of a Sheep, let it be held to the fire until it be black, and then let it be made into a Pouder: afterward let it be mingled with Rose water that it may become like unto Varnish; with the which let the part affected (with a feather) be anointed thrice every day, until it be wel.* Or,

Take *Barley meal, Bean meal, the meal of Lentils, of each one ounce and half; the pouder of red Roses, Wormwood, the prickly Dock, of each half an ounce: boyl them in the Decoction of Pomegranate rinds, Pomegranate flowers, Plantane: add hereto afterward the Oyl of Myrtle, and Honey, of each a sufficient quantity, and make an Unguent.*

Unto which (if use and need require it) we may also add and mingle the flower of Brass, and such like. And the very same likewise are convenient in the *Herpes Esthiomenos*; as for instance:

Take *Sumach, Plantane, Galls, of each an ounce and half; of branny Bread one ounce; Pouder of Roses half an ounce: boyl them all in Wine, and make a Cataplasm.* Or,

Take *cleansed Barley, Lentiles, Beans, of each one handful; Arnogloss (or Lambs Tongue) two handfuls; Pomegranate flowers, Roses, the grains of Myrtle, Sumach, of each half an ounce. Let all except the* Barley *be grossly poudered, and then boyl them in Wine until the Barley be soft, and make hereof a Cataplasm.* Or,

Take *the Rinds of the Pine tree burnt and washed a dram and half; Ceruss three drams; Frankincense one dram; Goats fat six drams; Oyl of Myrtle two ounces; Wax as much as wil suffice: make herewith an Unguent.*

But if we have a mind to dry more than ordinarily, we may ad the prepared file-dust of Iron, the flower of Brass, and Lime washed.

This is likewise commended:

Take *the spume or froth of Silver half an ounce; the juyce of Leeks and Beets, of each five ounces: Mingle them, &c.*

Hieronymus Fabricius writeth that (with very good success) he made use of this following Remedy:

Take *the juyce of Tobacco three ounces; green or Citron-coloured Wax two ounces; Rosin of the Pine tree an ounce and half; Turpentine one ounce; Oyl of Myrtles as much as wil suffice for the making and forming of a soft Searcloth.*

But if the Ulcer be already putrefied, we must then betake our selves to the Remedies that are stronger and more forcible; such as are the little sweet Bals of *Andro, Musa,* and *Polyidas*: as for example;

Take *Litharge, and Ceruss, of each two ounces; the Rinds of Pomegranates half an ounce; Myrrh one dram; Frankincense a dram and half; the flower of Brass and Allum, of each a dram; and with the Oyl of Myrtle and Wax (a sufficient quantity of each) make an Unguent.*

But if these wil not serve the turn, and that the Ulcer and putrefaction creep further, and become broader, we must then have recourse unto the stronger sort of Remedies.

They refer likewise unto cholerick Tumors those that we cal *Phlyctænæ, Impetigines, Lichenes, Sudamina,* and *Epinyctides.* But because that these little risings or swellings proceed not from pure Choler, but from Choler mingled with serous and salt Humors; we wil therefore

treat

treat of them below, with the reſt of the Tumors of this kind.

Chap. 18. *Of the Tumor* Oedema.

LIke as thoſe Tumors that we have already hitherto handled, have their original from hot Humors; ſo there are likewiſe ſome certain peculiar Tumors that ariſe from cold Humors; and in the firſt place, *Oedema*, that hath its original from Flegm. For although *Hippocrates*, and other ancient Phyſitians under the name of *Oedema* underſtand al other Tumors whatſoever in general; yet notwithſtanding thoſe of latter times by *Oedema* do underſtand ſome one certain kind of Tumor only, and this they ſpecially term *Oedema*; being a Tumor that is lax or looſe, ſoft, without pain, yielding unto the touch and compreſſion of the fingers, having its original from thin flegm, or elſe from the more cold and moiſt part of the Maſs of blood.

The Cauſes.

The containing Cauſe of this Tumor is that flegm that is contained in the blood, to wit, if it be ſo increaſed, that it irritate and ſtir up the Expulſive Faculty. For then Nature being ſtirred up and provoked thruſteth forth the matter out of the greater Veſſels unto the leſs, and expelleth it from the more noble parts unto the weaker, until at length it be received and retained by the moſt weak and infirm part. The cold and heavy Humor it ſelf likewiſe very often by its own weight tendeth downwards, and alſo unto the extream parts. And thereupon it is, that although the *Oedema* may be excited in al parts whatſoever of the body; yet notwithſtanding it chiefly and more eſpecially ariſeth in the Hands, and the feet, (as is evidently appeareth in Perſons that are Hydropical, Cachectical, and Phthiſical) in regard that thoſe parts are more remote from the fountain of heat. But now this *Oedema* is not ſuddenly generated, but by degrees, and by little and little. For why? the Humor is thick, and therefore altogether unfit for any ſpeedy and ſudden motion.

Galen, in his ſecond Book to *Glauco*, and third Chapter, determineth that the *Oedema* is cauſed by a Pituitous or flegmy ſubſtance, or elſe by the Spirits when they are ful of vapors; and ſuch a like Tumor or ſwelling happeneth in dead Carkaſſes. From which place (as likewiſe from the 14. of his Method of Phyſick, Chap. 4.) *Johannes Philippus Ingraſſias*, in his Book of Tumors, the firſt Tome, page 113. endeavoreth to prove a twofold kind of *Oedema*; the one from thin flegm; the other from a vaporous ſpirit: and that (to wit, the former) he aſſerteth to be a Diſeaſe; and the latter a Symptom only that followeth upon Phthiſis, and the water betwixt the Skin, (one ſpecies of the Dropſie) and the Cachexy. But yet although it be not to be denied that Carkaſſes (in the very firſt beginning of their putrefying, and as it were a certain kind of fermentation) ſwel up in ſome ſort; yet that in the Cachexy, or Phthiſis, the *Oedematoſe* ſwellings of the Feet ſhould in this ſame manner be cauſed, I cannot eaſily beleeve; in regard that ſuch a like putridneſs doth not then happen; but it is far more credible, that ſuch like Tumors are cauſed from a ſerous wheyiſh Humor abounding in the body, and deſcending unto the Feet, and there abiding and ſticking faſt, as in a part more cold than the other parts of the Body. And be it indeed granted and admitted, that in the ſimilar parts there may be ſome kind of flatulent Spirit collected, and that it may lift up the part into a Tumor; yet notwithſtanding this Tumor is not properly *Oedema*, but is rather to be termed *Empneumatoſis*, or *Emphyſema*. And albeit ſuch a like Tumor is by *Galen*, in his 14. Book of the Method of Phyſick, Chap. 4. called a Symptom; yet we ſay, that *Galen* then uſeth the name of a Symptom (in the general) for every Affect preternatural that followeth another.

But if we wel weigh and conſider what this Tumor properly is, we affirm that it is altogether and in al reſpects a Diſeaſe; in regard that it is magnitude augmented, and for the moſt part an impediment and hindrance unto men in their walking. And although ſuch an *Oedema* doth not indeed require a peculiar Cure; yet notwithſtanding it is not for al that to be razed out of the number of Diſeaſes, and placed among the Symptoms. For thoſe Diſeaſes that ſimply depend upon other Diſeaſes require not any proper and peculiar kind of Cure; but thoſe being removed, theſe likewiſe are taken away.

But now that very Humor that is the cauſe of *Oedema* is generated by an error and default in the ſanguification; touching which we have ſpoken in the third Book of our Practice, third Part, ſecond Section, and firſt Chapter.

The Signs Diagnoſtick.

Oedema is known in this manner: The Tumor is ſoft, and looſe; and if it be preſſed down with the finger, it eaſily yieldeth and giveth way by ſinking, and ſo there is a little pit and print of the finger left behind. For the moiſt flegm ſofteneth and looſeneth the part, and is more thick than ordinary, and therefore the more unfit for motion. It is either altogether without pain; or certainly if there be any it is very little, and ſcarcely ſenſible. For the flegm looſeneth the part; neither doth it by diſſolving unity excite any pain. The colour is ſomwhat white; there is an abſence of al heat; neither is there in this (as in other Tumors) perceived any kind of pulſation or beating. By which ſaid ſigns it is eaſie to diſcern an *Oedema* from other Tumors.

Prognoſtick.

Prognosticks.

1. *Oedema* in it self is a disease of no danger; for neither is the disease it self great, neither is the cause thereof of a dangerous consequence, nor is there any il Symptom therewithal conjoyned. And if there be (as indeed there often is) any danger unto such as are affected with this *Oedema* (as it hapneth in the Phthisis, Cachexy, and the Dropsie) this chanceth not by reason of the *Oedema*, but from those Diseases that the *Oedema* followeth. Whereupon we ought to distinguish whether the *Oedema* arise of it self, or else whether it follow upon other Diseases: since that the *Oedema* that followeth after the more noted and considerable faults of the parts designed for Nutrition, wanteth not for danger. For although it be true, that oftentimes (without any danger) the Feet swel after Diseases of long continuance (from crudities collected by the disease) yet notwithstanding if such like *Oedema's* shall happen from a Refrigeration, or by reason of any other fault in the Liver, they are then dangerous; and threaten death by reason of those causes upon which they depend. But if there be no such thing joyned together with the *Oedema*, then there is no danger at al to be feared.

2. But yet, although *Oedema* be a disease without any danger; yet notwithstanding, it is of a long continuance; for the matter is colder, and therefore it cannot be overcome but in a longer time.

3. But yet it is terminated by a Resolution; unless (which sometimes happeneth) the matter be hardened.

The Cure.

As touching the Cure, we must first of al consider (as was said before) whether the *Oedema* follow any other Disease of the more noble parts. For if this shal happen, our care ought especially to be, that the Disease upon which it depends be taken away; since that unless this be taken away it cannot be cured, and that if this primary Disease be removed it then vanisheth of its own accord. If yet notwithstanding the *Oedema* bring along with it any trouble, and that it prove hard to be cured, it wil not be amiss then to rub the part wel with Oyl mingled with Salt, or to foment it with a Spunge soaked in Wine, in which Wormwood hath been boyled. But if the *Oedema* arise without any other Disease, then in the first place, the cause from which the matter is supplied is to be removed and taken away. And therefore in the very first beginning, the course of Diet that is to be ordained must be such that in the least tendeth not to the generating and breeding of flegm, but rather such as wasteth and destroyeth it. And therefore let the Air in which the sick person abideth be dry; and likewise, let the meat and drink that he lives upon have a power and quality of attenuating and drying. Let the sick party therefore be very sparing and temperate in meat and drink, that so the Natural heat be not oppressed and overwhelmed, and so by the weakening of it Crudities be generated; but that the said heat may rather wast and consume those crudities, and the more fitly and effectually work upon them. Let his Bread be wel baked, and leavened: and let him altogether abstain from bread unleavened; and let him but seldom eat either Pot-herbs or Broths. Fish is altogether unfit for him, unless it be fresh River fish, and of them such as are of a more solid substance, and these likewise (even as al other his food) are to be seasoned and sauced with Spices and drying herbs. Al endeavor must be used that the Belly may dayly discharge its office; which if of it self it cannot do, it wil then be requisite that before his meals he take some Aloes, which looseneth the Belly, and consumeth and drieth up the superabundant humidity. Before meals (if it may be done without any offence and prejudice unto the part affected) let the sick person exercise himself, that so the superfluous moisture may be consumed, and the Native heat excited and stirred up: and to conclude, let him sleep only in the night, and let his sleep then likewise be but short.

Secondly, In an *Oedema* properly so called Venesection hath no place at al; for here the blood is no wayes peccant, but only the flegm: but the cold and crude humors in the body are to be concocted and evacuated. And first of al, the matter is to be digested and concocted by Medicaments that heat and dry, such as are elsewhere often propounded in the preparation of the flegmy humor; of which a certain Hydromel or Oxymel may most fitly be compounded. But yet notwithstanding if the humor be only wheyish, there is then no need at al of concoction.

Afterward the matter is to be evacuated by Medicaments that draw forth the flegm, which are elsewhere propounded. As for what concerns the part it self that is affected, the pituitous or flegmy humor which hath flown together into it ought to be evacuated; and this may be done by Repellers and Digestives, or those things that discuss and scatter. But if Repellers be made use of, they are to be administred, not so much to drive back the humor, as to confirm, and strengthen the part, and to dry up and consume the matter; unto which likewise there may not unfitly be added some of those Remedies that have in them a power and virtue to discuss. To this end and purpose, *Galen* maketh use of a new Spunge (or if a new one may not be had, than any other) throughly wet and soaked in Nitre and Ley, and Posca, that is, a mixture of Vinegar and Water. There may likewise be used the courser part of Hemp (which we cal Hurds) instead of the Spunge. Which said Medicament if it accomplish not our desire, the quantity of the Vinegar may then be augmented,

and

and a little Alum therewith mingled. And if neither this effect our purpose, nor satisfie our expectation, we ought then to betake our selves unto those that are stronger and more forcible. As,

Take Flowers of red Roses, Camomile, the Leaves of Myrtle, and of Wormwood, of each half an handful, Pomegranate Flowers, and the Cypress Nut, of each one handful; Alum, and common Salt, of each one ounce and half; boyl them in Vinegar and Water, or in Ley, and so apply it with a Spunge, a Linen Cloth, or Hurds. Or else,

Take the Leaves of the Sallow Tree, Myrtle, Wormwood, the Flowers of Camomile, and of St. Johns-wort, of each half a handful: let them be all boyled in Ley until all the Ley be consumed; afterward, let them be wel pounded and bruised, and then add the Oyl of Myrtle, of Roses, and of Wormwood, of each one ounce; Salt half a handful, Nitre one ounce; make a Cataplasm. Or,

Take Cypress Nuts, Pomegranate Flowers, of each half a handfull; Flowers of Camomile and red Roses, and the Leaves of Wormwood, of each half a handful, the meal of Barley and Lupines, of each half an ounce, Alum three drams; Aloes and Myrtle, of each one dram; Saffron one scruple; boyl them in a sufficient quantity of Water and Vinegar; and make a Cataplasm.

Afterward in the state we are to proceed unto those things that discuss and dry much. For this purpose there is commended the Water of Lime, or a Ley of the Vine ashes applied with a Spunge; Or,

Take Marshmallow Roots, one handful, the Flowers of Camomile and Melilote, of each half a handfull; boyl them in Wine and Vinegar, adding afterwards of Hoggs Fat two ounces, old Oyl half an ounce, the Spume or Froth of Silver one ounce; Mingle them, and make a Cataplasm.

That Medicament is also very efficacious that is made of Rue, Honey, and Salt. Or,

Take Sulphur one ounce, Pigeons Dung ten drams, Bean meal one ounce and half, the meal of Lupines one ounce, Honey one ounce and half; and so make a Cataplasm with the Decoction of Camomile flowers. Or,

Take Sulphur, Myrrh, Salt, of each one ounce, old Oyl and Vinegar, of each as much as will suffice, and make a Liniment. Or,

Take Bryony roots two ounces, Wormwood, Bearfoots, Camomile, Melilote, of each half a handful; boyl them in Water or Honey, and being wel bruised & searced, add to them the powder of red Roses, the Meal of Beans and Lupines, of each half an ounce; old Oyl as much as will suffice, and make a Cataplasm. Or,

Take the Root of Asphodil, and the wild Cucumber, white Lilly roots, and Flowers of Camomile, of each one handful; boyl them untill they be soft, and then add of Leaven, Tartar, washed or slaked Lime, and Sulphur, of each an ounce, Frankincense six drams, the Fat of a Hart, the Marrow of the Thigh-bones of Oxen, of each ten drams; make a Cataplasm.

There is likewise commended Ox dung, or Cow dung; for it both mollifieth and resolveth; of which with Sulphur, Frankincense, Honey, Vinegar, and the Broth of a Cabbage or Colwort, there may be made a Cataplasm.

In the applying of all which Medicaments, it is requisite that we observe, that before ever the Emplasters, or Unguents, and Liniments, be applied, the part be first made hot by frictions or rubbings and fomentations; for otherwise the Medicaments will not easily effect and accomplish our desire and expectation, by reason of the coldness of the part. The frictions may be made with hot Linen Cloaths; the fomentations may be of the Decoction of Camomile flowers, and Melilote flowers, and of the Leaves of Betony, Sage, Rosemary, Lavender, Organy, Wormwood and the like. For by the said fomentations and frictions the heat together with the blood is called back unto the part; and the excrements and superfluous humors are somwhat dispersed and scattered.

But if it be so that the *Oedema* seem to wax hard, and to pass into a *Scirrhus*, then we are likewise together with the former, to make use of Emollients or mollifying Medicaments. And for this use and purpose there is to be applied Vinegar, in which the *Lapis Pyrites* (we commonly call it the Fire-stone) or a piece of Mill-stone taken red hot out of the Fire hath been quenched; and after this the part is to be anoynted with old Oyl in the which the Root of the Wild Cucumber, and Marshmallow Roots have been boyled. Or,

Take the Mucilage of Marshmallow roots, Linseed, Fenugreek, Goose fat, the Marrow of a Leg of Veal, the Flower-de-luce root, Camomile flowers, of each two ounces; Styrax liquid, Mirrh, Frankincense, and oyl of Camomile, of each one ounce; Wax as much as wil serve the turn; and so make an Emplaster.

But touching these Remedies we shall speak further, when we come to treat of a *Scirrhus*.

And although indeed it be true, that the *Oedema* is most frequently discussed and dispersed by Resolution; yet sometimes notwithstanding (as is apparent out of *Hippocrates* in his Book of Prognosticks Text 27.) it cometh to a suppuration, but this is but seldom, to wit, if it be in a place somwhat hotter than ordinary, or else that any other humor be therewith mingled, as it happeneth in the *Oedema Phlegmonodes*; and this if it happen there is then perceived in the next adjoyning part both a pain, and a pulsation or beating. And therefore at such a time the Suppuration is to be furthered

furthered and haſtened on by thoſe Medicaments that we call Emplaſtick; ſuch as are *Diachilon ſimplex*, and other Remedies made of the Roots of Marſhmallows, the common Mallows, Linſeed, Fenugreek, with the Fat of a Hen, or ſuch like. As for example,

Take *Bearfoot, Marſhmallows, the Roots of white Lillies, of each one handful; boyl them, and when they are ſufficiently bruiſed, add to them the meal of Linſeed, and Fenugreek, of each two ounces; Hogs Greaſe, and Hens fat, of each three ounces; Saffron half a dram, and thereof make a Cataplaſm.*

The matter being concocted and ſuppurated, we are not to expect a ſpontaneous or ſelf-effecting Cure, in regard it wil be a long time ere it come to this. Wherefore let the place be opened either with the Inſtrument for that purpoſe, or elſe with a potential Caurery; and afterward let the Impoſtume be throughly cleanſed and purged with Turpentine, Frankincenſe, Honey, the Juyce of Wormwood, and Honey of Roſes: furthermore, let the Cavity or hollowneſs be filled up with the Unguent *Baſilicon*, the Unguent *Aureum*, & the Unguent of Betony, and ſuch like; and at length let there be a Cicatrice drawn over it.

Chap. 19. *Of a* Scirrhus.

HAving treated of thoſe Tumors that ariſe from the Blood, Choler, and Flegm; and it now remaining that we handle thoſe Tumors that ariſe from Melancholly and black Choler; and it being ſo that a *Scirrhus* (to ſpeak the truth) ariſeth from both Melancholly and Flegm, the next thing therefore that we have to do, is to treat of the *Scirrhus*. Now then a *Scirrhus* is a hard Tumor without any ſenſe or pain (or if there be any it is certainly but very little) ariſing from a thick humor that is Viſcid, Clammy, and Cold; ſuch as is the melancholly humor and flegm fixed and faſtened in the parts. For there are two humors, (to wit, Melancholly and Flegm) out of which either ſingly and ſeverally, or elſe mingled together, the *Scirrhus* ariſeth, as they commonly determine. Now here (in this place) by Melancholly we are to underſtand, not that black humor which ariſeth either from the Natural and aduſt Melancholly humor, or elſe from yellow Choler aduſt; but here we are to underſtand that Melancholly that is Natural, and properly called the Melancholly humor, to wit, the thick and more feculent or dreggy part of the Blood, or elſe likewiſe the Natural Melancholly Excrement, or elſe alſo (thirdly) a thick humor ariſing from an hardned Inflammation; the which if any one ſhal pleaſe to term Preternatural, I wil not in that gainſay him. But by Flegm we are not to underſtand that Natural Flegm, or the Flegmatick humor (which is moiſt and thin, and from which the *Oedema* proceedeth) but a thick Flegm, extraordinary dry, Glutinous, Viſcid, and Clammy. Of both theſe humors retained in the part over long (whenas the more ſubtile and thin parts thereof are vaniſhed and gone, and the more thick and groſs parts left behind) is the *Scirrhus* generated. For although ſome humor that is thick may flow unto ſome certain part; yet notwithſtanding a humor ſo thick and glutinous that it inſtantly cauſeth and produceth a *Scirrhus*, doth not eaſily flow unto any part whatſoever, but it by degrees and after ſome time becometh ſuch in the very place affected, whenas the thinner part of the humor being waſted and conſumed, the thicker and groſſer are left to remain behind. From whence it is, that (for the greateſt part) the *Scirrhus* followeth upon other Tumors (as for inſtance, Inflammations, *Eryſipela's* and *Oedema's*) when they are not ſufficiently and rightly cured, and that the thinner parts by means of heating Medicaments are either unſeaſonable, or overmuch and exceſſively diſſipated; or elſe are by Repellers and Aſtringents repreſſed, ſo that the more thick and groſs parts only are left behind; which being further incraſſated and thickned, do cauſe and produce this Tumor, that (as we ſaid before) is hard, and without pain and ſenſe. From all which Premiſes it may eaſily be collected, that this Tumor is not ſuddenly all at once generated, but by little and little.

Yet notwithſtanding *Paræus* diſſenteth from this common and received Opinion; and aſſerteth that the *Scirrhus* is cauſed, not from the excrementitious humors, but from an alimentary juyce (yet ſuch as is more thick than is fit and convenient for the nouriſhing of the fleſh) when it becometh hardened; unto which notwithſtanding there is (ſaith he) another humor adjoyned: and this hardening proceedeth (as from divers other cauſes, ſo likewiſe) from an Inflammation; not that the blood that is not diſcuſſed or ſuppurated is thus hardened, or condenſed by the over frequent and unſeaſonable application of cold things; but that the blood being diſcuſſed by the vehement heat of an Inflammation, the juyce and moiſture of that part that was inflamed is thickned and hardned.

But now a *Scirrhus* is twofold, *viz.* Legitimate (as we may ſo term it) and Illegitimate. Which ſaid diſtinction (as *Fallopius* truly tels us) is not taken from the diverſity of the matter, and the conteining Cauſe, but from the divers and different accidents and proprieties of the matter. For before ſuch time as all the more ſubtile and thin parts are either diſſipated or conſumed, there is as yet no abſolute *Scirrhus*, neither do all things then want ſenſe, neither is there as yet any perfect hardneſs appearing. But it (al the thinner parts being waſted and conſumed) only the thicker ſhal remain behind, and theſe ſhal harden even almoſt unto the hardneſs of a Stone;

and that the part is void not only of al pain, but likewise even of al sense; then the *Scirrhus* is now already absolute and perfect. But perhaps there can nothing be said to the contrary, why we may not term the *Scirrhus* that is not as yet absolute impure likewise, and bastard, or spurious. Or if this distaste, and please not; the *Scirrhus* (we say) may furthermore be divided into that which is pure, and truly so called, and that that is impure and spurious or counterfeit: and that may be called pure which hath its Original from melancholy alone, or from thick flegm; and that impure and spurious which hath another humor mingled together with it, from whence it is called *Scirrhus Phlegmonodes*, or *Scirrhus Cancrosus*. There be some certain Authors that give us also another difference of a *Scirrhus*, from the parts wherein it resideth. For although in very many parts it hath no peculiar appellation, but is only defined by adjoyning to it the name of the part affected (as we say the *Scirrhus* of the Liver, and the *Scirrhus* of the Spleen) yet notwithstanding in some certain parts it hath a proper appellation: for in the Nerves it is called *Ganglion*, in the Glandules (or kernels) *Struma*, in the Joynts *Porus*; of which in their proper places.

Signs Diagnostick.

The *Scirrhus* is known from two signs especially, to wit, the hardness, and the absence or want of pain: unto which this may likewise be added, That when it is pressed it wanteth sense; and then we say, that the *Scirrhus* is altogether absolute and confirmed. And it is not to be wondred at, that the part thus affected should have no sense, or that there should be so little, if any sense at al, in a *Scirrhus*; for both the influx of the natural spirits is hindered by the matter that is impacted and fast fixed; and also the very temper it self of the Member is so changed that the part becometh altogether stupid. Others there are that add other signs also; viz. a Color somwhat black and wan; which yet notwithstanding is only a sign of that *Scirrhus* that ariseth from the Melancholy Humor; and if the temper be very cold, by reason of a thick and cold Humor, it is then likewise perceived by the touch.

The Differences.

The Differences are taken from the Sense, either dull, or none at al. For if there be no sense at al present, the *Scirrhus* is now Legitimate and absolute: but if there be yet any manner of sense left remaining, it is not Legitimate and absolute. There are some likewise that add this, that in a Legitimate *Scirrhus* there grow hairs upon the part. The color wil inform us whether it hath its original from flegm, or from Melancholy; this color in flegm is somthing white; but in Melancholy, blackish, and wan.

Prognosticks.

1. As for what concerneth the Event, that *Scirrhus* that is altogether destitute of al sense, is incurable.

2. But that *Scirrhus* that is not destitute of al sense, although it be not altogether incurable, (especially if at the beginning fit and proper Remedies be applied) yet notwithstanding it is not very easily cured; especially if it stick in any one of the more noble parts, as the Liver, or the Spleen likewise; since that the Liver and the Spleen wil hardly bear or admit of those so strong Medicaments which are requisite in a *Scirrhus* that is perfectly hardened; and those that are weak avail but little or nothing.

3. If there be any hopes of a Cure in a *Scirrhus*, yet this is not to be brought unto perfection, but in a long time. For to mollifie and soften the matter that is thick, cold, and hard, is a thing that is not easily done; neither indeed can it be done at al, but by little and little, and in a longer time than ordinary.

4. But when they may be cured, it is to be done in a twofold manner: either by Resolution and Discussion; or else by Maturation and Suppuration. But it is seldom that they are suppurated, and then likewise not without danger: for when they are suppurated they easily degenerate and pass into Cancers; especially those of them that proceed from a Melancholy Humor.

The Cure.

As for what therefore concerneth the Cure, although there be a plain and absolute Tumor or Swelling already appearing, and that in the Cure we ought especially to have respect unto the containing Cause; and that we are to do our endeavor that it may be removed by Topical Remedies; notwithstanding the Antecedent cause is also not altogether to be neglected; and here we must prevent the augmentation of the Malady by the supply of any new matter.

Wherefore (first of al) whatsoever it be that generateth thick blood is carefully to be avoided; and such meats are to be chosen that are easily concocted, and such as make a supply of good Nutriment; and such as incline and tend to humidity and moistness.

Secondly, the Humors (whether flegmatick or melancholick) are (being first wel prepared) to be evacuated by convenient and fit Medicaments; touching which we have already elsewhere spoken.

But thirdly, and principally, we ought to use our utmost endeavor, that the Containing Cause and the matter that maketh the *Scirrhus* be quite and clean taken away. But as for Repellers, here is no place for them. For since that the matter is both thick and cold, it wil not yield nor give place unto Repellers; but rather by the use of them

them is the more incraſſated and thickened, and as it were impacted, and made to ſtick the faſter in the part. Neither likewiſe are thoſe Medicaments that greatly heat and dry fit and proper in this place; for by theſe the matter is only the more hardened. But thoſe Medicaments that are here moſt conveniently adminiſtred, are, thoſe that have a vertue and quality to mollifie that that is hardened, and ſuch as afterward diſcuſs and ſcatter the matter when it is ſoftened. Malactick or mollifying Medicaments are therefore to be adminiſtred and applied, that are of a hot temperament, and yet notwithſtanding but meanly, and not greatly drying; but neither yet manifeſtly moiſtening; but ſuch as obtain as it were a certain middle nature between Moiſteners and Dryers, and ſuch as accompliſh (as it were) a reſolution and ſoftening of the hardened ſubſtance. And ſuch are, *The Oyl of ſweet Almonds, the Oyl of Camomil, and white Lillies, Hens fat, Gooſe fat, Swines fat, the Marrow of Veal, and of a Hart, the Mucilage of Marſh-mallow Roots, Linſeed, and Fenugreek; and ſuch are likewiſe the Leaves and Roots themſelves, of Marſh-mallows, Mallows, Linſeed, Fenugreek, the Root of white Lillies, Bears-foot, dried Figs that are ful and fat, Wax, &c.* And ſtronger than theſe, are, *Bears fat, old Oyl, Bdellium, Styrax liquid, liquid Pitch, fat Roſins, Ammoniacum, Galbanum.* But we muſt carefully obſerve, when thoſe Medicaments that are more mild and moderate are to be made uſe of, and when the ſtronger ſort.

In a *Scirrhus* that is but newly begun we are to uſe thoſe Medicaments that are of the milder ſort: but in an old and inveterate *Scirrhus* that is become hard, thoſe Remedies that are more ſtrong and prevalent are to be put in practice. Moreover, the very Body it ſelf, and likewiſe the part affected, are to be conſidered. For unto an hard body the ſtronger ſort of Medicaments are to be applied; but for the tender and more ſoft bodies the milder and gentler ſort of Remedies are moſt convenient. The part if it be harder and thicker (as if the *Scirrhus* be in a Tendon or Ligament) then we ought to adminiſter and make uſe of the ſtronger Medicaments. And in the general we are to obſerve this for a Rule, That we handle the *Scirrhus* with al manner of care and caution. For if we adminiſter thoſe Remedies that do overmuch and more than is fitting Reſolve, then (as we alſo already ſaid before) the *Scirrhus* paſſeth into a ſtony hardneſs. But if we too much mollifie, there is then a fear that the *Scirrhus* may degenerate into a Cancer. Wherefore it is moſt ſafe in this caſe to follow the counſel and advice of the Ancients, that we uſe not alone any Medicament that hath in it a power either only to dry, or only to moiſten; but that we adminiſter ſuch Remedies as mollifie and diſcuſs; not together, but by turns, and one after the other; or otherwiſe that we mingle together Emollients or Mollifiers with Digeſtives. And for this uſe *Galen* commendeth the fomentation of Vinegar, wherein the fire-hot *Pyrites* ſtone hath been extinguiſhed in this manner; Let the part be fomented with the Decoction of Marſh-mallows, Mallows, Bears-foot, the ſeed of Fenugreek, Linſeed, and the like Emollients. Afterward, take the *Pyrites* or Fire-ſtone, or a piece of a Mill-ſtone, and having made it red hot caſt it into the Vinegar; or elſe let the Vinegar be caſt and poured upon that hot and glowing ſtone, and then let the vapor of the Vinegar ſteam up and be received into the Member affected. After this, let the Emollients be again adminiſtred; and let theſe Remedies be (as they ought) often repeated at many ſeveral times, and ſucceſſively. And in this manner the *Scirrhus* that is almoſt deſperate may be cured. But if it be over tedious to uſe theſe Medicaments (in the aforeſaid manner) at ſeveral times, and by turns, then let them be al mingled together. For by this means, at one and the ſame time, and together, the Tumor is mollified, and that that is mollified is diſcuſſed and diſſipated by exhaling and breathing forth. For which end and purpoſe, out of the Simples before-mentioned there may be divers Medicaments compounded. As,

Take *Unſalted Butter, Scammony, Wax, of each as much as ſhal be thought ſufficient; and then mingle them.* Or,

Take *the Meal of Fenugreek, Linſeed, Marſh-mallow Roots, the Pouder of the Holly-hock Root, of each one ounce; boyl them, and afterwards add, of freſh Butter an ounce and half; Styrax liquid, Bdellium, Ammoniacum diſſolved in Vinegar, of each half an ounce; Mingle them.* Or,

Take *Marſh-mallow Roots, the Roots of white Lillies, boyled and wel bruiſed, of each three ounces; fat and ful dried Figs boyled, in number ſix; Ammoniacum and Bdellium diſſolved in Vinegar, of each one ounce; Styrax liquid half an ounce; Gooſe fat, Hens fat, the Marrow of a Leg of Veal, of each three ounces; Oyl of white Lillies, Oyl of Camomil, and Wax, of each a ſufficient quantity; Make an Emplaſter.* Or,

Take *the Meal of Beans, Fenugreek ſeed, Lin-ſeed, of each ſix drams, the Root of Marſh-mallows one ounce; Pitch five drams; Gooſe fat, as much as wil ſuffice; Make an Emplaſter.* Or,

Take *the Mucilage of Marſh mallow Roots, and Fenugreek, of each one ounce; Fat dry Figs three ounces; Oyl of white Lillies, Camomil, Lin-ſeed, of each two ounces; Hens fat, Gooſe fat, Swines fat or Hogs Greaſe, Goats ſuet, Turpentine, Litharge of Gold, of each four ounces. Boyl them al, until the moiſture be conſumed, and then with a ſufficient quantity of*

Wax, and adding thereunto Ammoniacum, and Galbanum dissolved in Vinegar, of each three drams; and Flowerdeluce Root wel bruised two drams; make an Emplaster. Or,

Take *Ammoniacum, Bdellium, Galbanum, Opopanax, Styrax liquid dissolved in Vinegar, of each one ounce; Litharge of Gold ten drams; let them boyl in Vinegar: afterwards add, Pellitory, live Sulphur, of each half an ounce; Oyl of white Lillies and Wax, of each a sufficient quantity. Make an Emplaster.*

But now in the administring of these Medicaments we ought alwaies seriously to observe whether the *Scirrhus* arise from flegm, or else (in truth) from a Melancholick humor. For if it hath its original from this last, it is then more warily and cautelously to be handled, than if it proceeded from flegm, left that it turn into a Cancer; and especially, if it incline toward a suppuration, we must have a care that it be not too much irritated by hot Medicaments.

Chap. 20. *Of a Cancer.*

THe Cancer (by the Greeks called *Carcinos*, and *Carcinoma*, so termed because it resembleth the Water-Crab or Crevish) is generated from an adust Humor, or black Choler. And yet notwithstanding *Celsus* seemeth to put a difference between *Carcinoma* and *Cancer*. For in his fift Book, and 28. Chapter, he calleth the disease that we treat of in this Chapter only *Carcinoma*. But in the same Book, and 16. Chapt. he giveth the name and appellation of a Cancer (in general) unto certain creeping Ulcers; under which he likewise comprehendeth the *Erysipelas* that is exulcerated, the *Gangrene* also, and the *Sphacelus*. But yet notwithstanding al other Physitians whatsoever use the words *Carcinoma's* and *Cancers* as *Synonyma's*, that is, as words signifying one and the same Disease. For a *Cancer* is a Preternatural Tumor arising from black Choler, round, of a wan color, or somwhat blackish, painful; and which (when the Veins every where round about are filled and strut out) resembleth the feet of the Crab, Crevish, or Crawfish.

The Causes.

The Cause of a Cancer is black Choler, in which either yellow Choler, or the Melancholy Humor hath degenerated, by reason of its being burnt. For the Melancholy Humor, while it yet continueth to be Natural, and is not yet burnt, doth never cause or produce a Cancer, but another Species or kind of *Scirrhus*. But from the black Choler alone, if it be burnt, (which sticketh fast in the Veins, neither can it by reason of its thickness penetrate into those streight and narrow passages, as the Melancholy humor doth that causeth the *Scirrhus*) the Cancer is excited and generated. But now of this black Choler there is a certain difference; for some of it is more mild and moderate, or less hot and sharp; but then another sort of it is very sharp and hot. That which is more mild causeth a secret hidden *Cancer* that is not exulcerated; but that that is more hot and sharp exciteth an exulcerated Cancer. Now the said black Choler is more or less sharp, according as it is more or less burnt, or arise from a humor that is more or less sharp. Whereupon it is, That that which proceedeth from yellow Choler adust and burnt is worse than that which hath its original from a Melancholy humor. And look by how much the longer it abideth in the place affected, and by how much the more it is putrefied and burnt, by so much the more it is rendered the worse. And hence it is that the Natural Melancholy humor also which first exciteth a *Scirrhus* if it stick and abide long in the part, and especially then when it is not handled with al care and caution in the applying of heating and moistening Medicaments, it afterward exciteth and causeth a Cancer. But whether the Cancer be without any Ulcer or no; and whether the black Choler be mild and moderate, or else exulcerated, and the cause more sharp; yet however notwithstanding, in, and of it self it is alwaies without a Feaver; although accidentally a Feaver may happen thereupon. In the mean time (we say) the Cancer it self is a hot Tumor. For although some there be that doubt whether a Cancer be to be ranked and reckoned up among the hot or the cold Tumors; (as there be likewise that question whether black Choler be a hot or a cold humor;) and although by the Arabian Physitians a Cancer is accounted and reckoned up among the cold Tumors, and *Galen* seem to incline thereunto, in his Book of black Choler, Chap. 4. and in his 2. to *Glauco*, Chap. 10. yet notwithstanding it is by the same *Galen* in his Book of Tumors, Chap. 8, 10, 11. most rightly and truly reckoned up among the hot Tumors; since that it hath its original, not from the Melancholy humor cold and dry, but from black Choler, hot and dry. For albeit the Melancholy Humor may possibly give the first occasion of this Tumor; yet however notwithstanding the Cancer is not generated from it, unless the said Melancholy Humor degenerate and turn into black Choler; whether this happen in the Vessels, or in the part affected; like as somtimes a *Scirrhus* (as ere while we told you) that is produced from a Melancholy Humor may pass and turn into a Cancer. And this is the conjunct cause of a Cancer; to wit, black Choler, a humor hot and dry, sharp, Salt, corroding and corrupting al things; generated and bred from the heat of other humors, the heat now ceasing, or at least being not so vigorous that it may excite and cause a Feaver; as it is wont to be in a *Phlegmone* and *Erysipelas*.

It is likewise generated from other Causes. For now

now and then a hot distemper burneth up and inflameth the Humor, and so generateth black choler: and sometimes the Food (Meat and Drink) being such as hath in it a disposition and tendency unto the generating of such a like humor, by the frequent use thereof, and in process of time, becometh the Cause of black Cholet: and sometimes the very Spleen it self being grown weak, and not able to attract and draw unto it self that that is generated of the Melancholly humor, doth thereupon leave this humor in the Body, which after it hath been for a while detained in the Body is inflamed and burnt up. The very same likewise happeneth, if either the monthly Courses (in Women) be suppressed, or the Hemorrhoids obstructed.

And in truth, the Cancer is generated and bred in all the parts, both external and internal; and yet notwithstanding it especially appeareth (as *Celsus* tels us in his fifth Book, Chap. 28.) in the superior parts, about the Face, Nosethrils, and Ears, Lips, the Paps or Breasts of Women; which chiefly (by reason of their laxity and loosness) do very easily receive that humor; and then again (in regard of the consent and agreement it hath with the Womb) they readily admit of those vitious and naughty humors that ought to have been purged forth through the Womb.

The Signs Diagnostick.

At the first beginning the *Cancer* is not so easily known; because that at first it is scarcely so big as a Vetch or a Bean: but then afterwards, when it is grown, and hath gotten so much augmentation and enlargement that it is now lift up into a greater bulk, it hath with it then signs and symptoms so evident and so grievous, that it by any one may be most easily known. For this Tumor is hard, it hath a leaden, or wan, or blackish color; and yet notwithstanding this is more or less such, according to the diversity of the matter. There is present likewise a pain to attend it; the which (although it may indeed be sometimes greater, and sometimes less) yet notwithstanding the *Cancer* is never wholly without it. There is likewise present an heat, pulsation or beating; and round about (as it were in a Circle) it hath Veins distended, and strutting out with black Blood. Now although the *Scirrhus* arising from a melancholly humor hath some kind of likeness and affinity with a *Cancer*; yet notwithstanding by the aforesaid and other signs it may easily be discerned from it. For a *Cancer* hath evermore a pain and pulsation conjoyned therewith, together with an heat more than ordinary; and most commonly it beginneth of it self, and suddenly getteth encrease, so that from a very smal and inconsiderable bigness it becometh exceeding great and bulky; and there is for the most part a humor residing in the Veins, which said Veins being therewith filled very full resemble the Feet and Claws of Crevish or Craw-fish. But now in the *Scirrhus* there is no pain appearing; and for the most part it hath its original from the Change and alteration of other Tumors; and the humor that produceth the *Scirrhus* doth not chiefly and principally reside in the Veins, but in the spaces and Pores of the Parts; from whence also it is, that the Veins are not ample, wide, and large, neither turgid, and strutting out; and the increasing and growth thereof is much more slow than that of a *Cancer*. But now if the Cancer be already Ulcerated, then the Ulcer is nasty and stinking, the lips are swoln, thick, and pale or wan.

The Prognosticks.

1. In the general, every *Cancer* is a most grievous and a dangerous Disease; and such as is seldom or never cured. For the Cause thereof being over thick is obstinate and malignant; and oftentimes it seizeth and surprizeth even those Veins also that lie low and deep; insomuch that it cannot be removed and taken away, either by the purgation of the Body, or by Repellers, or Discussives, or cutting and lancing, or lastly, even by actual Cauteries and burning; for as for the milder sort of Remedies, it sleights and contemns them; and as for the stronger sort of Medicaments, it is by them exasperated.

2. Where there are secret and hidden Cancers, there it is best not to cure them; For they that are cured die within a very short time after, but those that are not cured of these aforesaid Cancers live a longer time, so saith *Hippocrates*, in the sixth of his Aphorisms, Aphor. 38. For why, those Cancers that before were not exulcerated when they have Medicaments applied to them may and do easily become exulcerated.

3. They likewise that have Cancers in the Cavity of the Body, or in the palate of the mouth, or in the Buttocks, or in the Womb, if they be either cut or burnt, the Ulcers cannot by any means be healed up, and covered over with a Cicatrice. But those that are thus affected while they lie under Cure are tortured and tormented (even to death) by the afflicting pain they undergo; whereas without a Cure (and if they shall not at all submit themselves unto the means tending thereunto) they may live a longer time, and with far less trouble and grievance; as *Galen* hath it in his Commentary upon the aforesaid Aphorism of *Hippocrates*.

4. Those Cancers only therefore are to be attempted in the way of Cure, which are and appear in the outward part of the Body; and there likewise it will be more safe to attempt the Curing of them by Medicaments in the very first rise of them (while they are yet but smal and inconsiderable) than when they are grown and become great; for then they are not to be cured without the help of the Hand; (which we term the Manual

nual operation) neither indeed so, unless they have their residence and situation in those parts that may without danger be lanced and burnt, together with the very Roots, that is to say, the Veins in them that are full of burnt or adust blood.

5. For when the Cancer hath once gotten possession of a great part; or when it sticketh fast in a more noble part, or any other that may not safely and conveniently be cut or burnt, it is then altogether incurable.

6. Yea moreover, (in the general) there are very many, and indeed the most Physicians, that are of opinion, that no Cancer confirmed and exulcerated can possibly be cured.

And it is oftentimes observed, That although Cancers be cut out, and now and then cured in the external parts; Yet notwithstanding, that the same have returned again either in the very same part, or else even in some other parts; as for instance, when the Cancer hath been cured in the paps or breasts another hath soon after risen and sprung up in the Womb. And therefore we ought rather, so far forth (and no further) to cure those Cancers that are already inveterate, and of the greater size, that their further growth and augmentation may be impeded and hindered.

Whether an exulcerated Cancer be contagious?

Zacutus Lusitanus will have it to be contagious; & he proveth it,

1. From Reason.

Cardanus in his first Book of Poysons, and 12. Chapter, affirmeth that the Cancer is not contagious; and yet he giveth us no reason at al for this his Assertion; but presupposeth, and taketh it for granted, as a thing apparent and manifest. Neither (to my best remembrance) do I know any one, who accounteth and esteemeth the Cancer to be in the number of contagious Diseases; excepting only *Zacutus Lusitanus*, in the first Book of his Practice, and Administr. of Physick, and 124. Observat. who doth it, and endeavoreth to prove it both by Reason and Experience. His Reasons are, 1. Because that in an exulcerated Cancer there is present a certain putridness and noysom stench (as it were of a dead Carkass) that by its purulency infecteth the body that is nigh unto it. His second Reason is, Because the Cancer is the same Disease with an *Elephantiasis*, and Leprosie of one only Member; but now the *Elephantiasis* is most contagious.

An Answer thereto.

But these his Reasons do not sufficiently conclude any thing. For first, Al things that are putrid and ill savoured and noysom are not contagious. For in a Gangrene and *Sphacelus* there is an extraordinary putridness and stench; and yet notwithstanding the stander by is not therewith infected. And moreover, although a Cancer hath some kind of similitude and resemblance with an *Elephantiasis*; they are yet notwithstanding several and different affects, as *Cardanus* in the place alleadged hath very rightly determined.

2. From Experience.

And therefore Experience is to be consulted. Now *Zacutus Lusitanus* in the place before alleadged bringeth in and produceth this Experience: He there writeth, That a certain poor woman having had a Cancer exulcerated in her Breast for many yeers together, and lying in bed with her three sons, they were all infected with the like contagion; & that she after five yeers dying, two of these her three sons seized upon and dispatcht by this Disease departed this life; but the third (somwhat stronger of constitution than the other two) after that the Cancer had been cut away by the hand of the Chirurgeon, with much pains and ado was cured and healed. But this being but one example, Experience is yet further to be consulted: and the rather in regard that it may be here objected, that those her sons might contract this Disease, not by contagion, but from an hereditary infection.

An Answer to the aforesaid Experience.

The Cure.

As for what therefore concerneth the Cure of a Cancer not exulcerated, in the very first place (and this indeed is generally to be practised in al Cancers whatsoever) before any thing else be done, we are to use our diligent endeavor to prevent the encrease of black Choler, and that none be generated for the future; and that what is already in the body may speedily be evacuated. The breeding of black Choler and the Melancholy Humor is to be hindered and prevented by the Patients abstaining from those Meats that may any way yield and afford matter to the black Humor; such as are al things that are thick, feculent, salt, bitter; and such are old cheese, flesh that is thick, old, salt, or smoak-dried, Garlick, Onions, Mustard, Pepper, and al other Spices. Let the sick person likewise shun and avoid al those things that do any way conduce to the generating of the black Humor; such as are Grief, and sadness of the heart, overmuch watching and want of rest, and the like. But rather let the Patient use a Diet that is moderately moistening and cooling; viz. Ptisan of Barley, Lettice, Mallows, Borrage, Succory, the four cold Seeds, Veal, Wether Mutton, Kids flesh, Chickens, Reer Eggs, River fish, the Whey of Goats Milk, and such like.

Further-

Furthermore, If there be any aduſt Humor already generated in the Body, let it be with al ſpeed evacuated. And therefore in the firſt place (if it be at al requiſite) blood may be drawn forth by opening a Vein. In Women, the provoking and bringing down their Courſes wil be moſt proper and convenient; and in men let the Hemorrhoids be opened, if it may be done. After this, let the body be throughly purged with thoſe Medicaments that evacuate the black aduſt Humor; among which there is eſpecially commended Epithymum, (we vulgarly cal it Mother of Tyme) black Hellebore, Fumitory; and the Compounds thence derived, viz. the Pils of Fumitory, and the Confection Hamech. But now that the Purgation may the better ſucceed, that thick and groſs Humor is firſt of al to be prepared; yea moreover, whenas the whol Humor may not at once and al together be evacuated, then the Purgers and Preparers are often to be repeated, by turns, and ſucceſſively. Now for this Affect, thoſe things that are very proper and convenient, are, the Syrup of Apples, of Fumitory, of the Juyce of Borrage and Bugloſs, Syrup of Lupulus or the Hop: or other Compound Medicaments like unto theſe. Neither wil it be amiſs, or any whit incongruous, likewiſe to ſtrengthen the Heart and the Liver; and if there be any diſtemper chanced unto either or both of them, to amend and rectifie it by Medicaments, of Borrage, Bugloſs, Roſes, Citrons, Sanders, Corals, Margarites, Pearls, and thoſe other Medicaments that are made and compounded out of theſe.

And then in the next place, we are to apply our ſelves unto the very part affected; And, 1. By Topicks the Matter that hath flown in is a little to be driven back again, and diſcuſſed; and the part is to be confirmed and ſtrengthened; and thoſe Medicaments that have in them a power and vertue of Repreſſing, Corroborating, and Diſcuſſing, are to be applied. For by this means, ſo much of the Cancer as is already generated is quite taken away; and likewiſe the further growth and increaſe thereof is prevented. But now, let thoſe Medicaments have in them a mediocrity (or mean) of ſtrength and vertue; and let them not be ſharp and biting. For if the Medicaments be over weak, they then afford no help or benefit; and again, if they be too ſtrong and violent, they then indeed either repreſs or diſcuſs the more thin parts; but for the more thick, they do not only leave them behind, but alſo render them the more unapt and unfit to be afterwards diſcuſſed and diſſipated. There is for this uſe and purpoſe very convenient, the Decoction or Juyce of Nightſhade, and of the ſeveral Species of Endive and Succory. But more eſpecially there are commended the Cockle-fiſh boyled, River Crabs or Creviſhes; and principally green Frogs, out of which there is a moſt excellent Oyl to be diſtilled, for the moderating of the pain, and the healing of the Cancer; the deſtillation is by deſcent, after this manner:

Take *Green Frogs, living either in the Reeds, or in pure and cleer Waters; fil their mouths with Butter, and afterward put them into an Earthen Pot that is glazed, and having in its bottom many little holes. Let this Pot be put into another Pot, and that other Pot put into and ſurrounded with the Earth, in the which it is to be as it were ſhut up: and then let as wel the Pot that hath the Cover, as that Pot which is put into it be carefully luted and ſtopt; that ſo nothing may exhale. Afterward, let the fire be kindled round about the Pot on every ſide; and the Oyl wil deſtil into the lower pot, which is to be taken forth, and together with the Pouder of the Frogs mingled, for the making of an Unguent.*

Others there are that make up an Unguent with the Aſhes of Crabs or Crawfiſh mingled together with Coriander ſeed, and the Oyl of Roſes. And here likewiſe we are to make uſe of the greateſt part of Metallicks waſhed, and ſo becoming altogether without any biting quality (their power and vertue being here of ſingular uſe:) ſuch as are Lead, Tutia or Pompholyx, Litharge, Ceruſs, Antimony. Lead is chiefly and moſt highly commended by al; and it may likewiſe be adminiſtred any manner of way. Whereupon it is that al thoſe Medicaments that are to be applied in the Cancer are moſt fitly and properly made up in a Leaden Mortar, with a Leaden Peſtle, touching which *Galen* is to be conſulted; ſee in his 9 Book of the Faculty of ſimple Medicaments, and the Chapter of Lead; which is made by rubbing together two Leaden Plates (whereon the Oyl of Roſes hath been poured) ſo long until the Oyl become ſomwhat blackiſh, and that it hath gotten the conſiſtence of a Liniment; or if in a Leaden Mortar the Oyl of Roſes be ſtirred about with a Leaden Peſtle, ſo long, that it likewiſe wax ſomthing black, and become thick. Or,

Take *Oyl of Roſes two ounces; the Juyce of Nightſhade an ounce and half; Ceruſs or white Lead waſhed, Lead burnt and waſhed, of each one dram: Litharge, Frankincenſe, Pompholyx or the ſoyl of Braſs, of each half a dram; White Wax as much as wil ſerve the turn: make an Unguent.* Or,

Take *Terra Sigillata or the Sealed Earth of Lemnos, Bole-armenick, Ceruſs, of each half an ounce; Tutia prepared two drams: Pouder of green Frogs three drams: Litharge one dram and half; Oyl of Roſes an ounce and half; Oyl of Frogs an ounce; Vinegar ſix drams; Wax a ſufficient quantity: ſhake and ſtir them about for a good while in a Leaden Mortar, and ſo make an Unguent.*

And indeed this is the ſafer way of curing Cancers that lie hid and ſecret in the body, and ſuch as are not as yet exulcerated. For albeit *Avicen*

command

command that the leſſer ſort of Cancers (and ſuch as may be perceived) be cut up by the very roots, and after this exciſion that the thicker blood ſhould be preſſed and ſqueezed forth on al ſides, and round about, and that the place be afterward ſeared and burnt with a Cautery, that ſo by this ſaid burning the reliques or remainders may be conſumed, the Member ſtrengthened, and the Hemorrhage or flux of blood hindered; yet notwithſtanding this kind of Cure hath much danger in it; and we ought here to remember that above alleadged 38. Aphoriſm, Section 6. For the Cancer (eſpecially if any thing great) if it be wholly cut forth, and as it were ſtub'd up by the roots, then inſtantly there wil follow thereupon (the Veins and Arteries being cut aſunder) an extraordinary and dangerous flux of blood; which if it be intercepted with a binder, then there wil be an extraordinary great and grievous pain excited in the other parts; if they be ſeared and burnt, this likewiſe cannot be done without much inconvenience; and yet nevertheleſs there wil be great danger of its returning.

The Cure of an exulcerated Cancer.

But now, whereas the moſt are of Opinion that the exulcerated Cancer is not at al to be attempted or medled with, yet notwithſtanding it being very inhumane to leave the ſick perſon (even in ſuch a Diſeaſe) altogether deſtitute of help and aſſiſtance, there is therefore by Phyſitians appointed and ſet down a twofold way and method of curing theſe exulcerated Cancers; the one true and genuine, which tendeth to the removal of the very Cancer it ſelf; the other only Palliative (as they term it) which eaſeth, aſſwageth, and in ſome ſort qualifieth the Cancer, ſo that the ſick perſon may live with ſomwhat the leſs pain and grievance. The true Cure is performed either by Inciſion, or Searing, or burning Medicaments; which indeed are moſt eſpecially to be adminiſtred, if the Cancer hath not yet attained unto any conſiderable growth and bigneſs; or elſe if it be in thoſe parts where it may without danger be cut forth, or burnt. It may be amputated and cut away even to the very quick, that ſo whatſoever is vitious and corrupt may be wholly taken away, ſo that there may be no fear left of any remaining contagion. And ſomtimes only cutting wil ſuffice, and by it the whol Cancer may be grubb'd up even by the very roots. The amputation being made, the blood is not to be ſuppreſſed and ſtopt from flowing, before it ſhal manifeſtly appear that al thereof that is vitious and corrupt be flown forth out of the Veins: afterwards dry Liniments are to be put upon the part that was cut, and the Ulcer is to be concocted or ripened, cleanſed, filled up with fleſh, and a Cicatrice drawn over it, and ſo the Vein to be ſhut up. But ſomtimes again, if the Cancer be overgreat, and black Choler hath likewiſe ſeized upon the greater and deeper Veſſels, then in this caſe Section alone wil not ſuffice, but beſides the ſaid cutting burning is alſo to be adminiſtred. And therefore in the firſt place, that Skin being taken off, the Cancerous part it ſelf, together with al the blackiſh Veins, is as much as poſſibly may be to be taken forth, and the blood likewiſe (according to the ſtrength of the Patient) is not inſtantly to be ſuppreſſed and ſtopt, but rather to be further preſſed and ſqueezed forth, that ſo al the black Choler may by this means flow forth of the Veins. After this the place is to be ſeared with a fire-hot Iron, that ſo the Hemorrhage and bleeding may thereby be ſtanched, and the reliques of the malignant matter waſted and conſumed. And at length thoſe things that take away the cruſt, cleanſe the Ulcer, generate and breed fleſh, and produce a Cicatrice, are to be adminiſtred. But others (leſt that the ſick perſon ſhould be endangered by the Hemorrhage and extream bleeding, or together with the loſs of his blood ſhould loſe his life alſo, and leſt the Chirurgeon by the flux of blood might likewiſe be hindered in his operation) do not in the like manner as aforeſaid amputate the whol Cancer, and after that at length burn the whol; but firſt of al they cut off a certain part thereof, and then (after that a ſufficient quantity and portion of the blood is flown forth) they burn and ſear the ſaid part; and then again a ſecond time they amputate and cut off another part thereof, and again burn it; and thus in this manner, by turns iterating and repeating the Section and amputation, as alſo the burning and ſearing, they do at length quite take away the whol part affected with the Cancer. The Cancer may alſo be burnt with Cauſtick Medicaments, among which there is commended Sublimate Arſenick. But there ought to be a ſpecial regard had unto the places and parts that lie round about it; neither in this reſpect may crude Arſenick be (without much hazard and danger) thus adminiſtred. That Arſenick is more ſafe that is poured forth mingled, and fixed with *Salnitre*, or the Salt of Nitre.

But now, in regard that the great fear that here eſpecially perplexeth Phyſitians is touching the recidivation and return of the Affect, thoſe Medicaments therefore that evacuate black Choler are often to be repeated, and likewiſe thoſe that have in them a power and vertue to draw forth the Hemorrhoids, and the Courſes. Inſtead of which (if they be wanting) ſome there be that cauſe Iſſues to be made. But in this caſe, we are not only to adminiſter ſuch Medicaments as prepare and purge forth black Choler, but thoſe likewiſe that reſiſt and oppoſe poyſons, and ſuch as are known to be expedient in regard of their whol ſubſtance, and ſuch as have in them the property and ſovereign vertue of Antidotes. And for this purpoſe we are to adminiſter Treacle and Mithridate, with Borrage, Cichory, and the Juyce or Syrup of Sorrel, the Broth of River Crabs out of Aſſes Milk, and

and the Antidote likewise that is made of their Blood.

Antonius Chalmetæus (in all kind of Cancers) commendeth this Water; which he likewise useth nine daies before the excision, or cutting forth of the Cancer.

Take *Thapsus barbatus or sweet white Mullein, the Root of Water Betony, of each two ounces; Dropwort, Spleenwort, Agrimony, Tormentil, Scabious, Avens, Toad-flax, of each one handful; Nettle seed three drams, Flowers of Elder, Rosemary flowers, of each one pugil or smal handful.* Make a Decoction, which may be dulcified with Sugar; with some part of which Decoction the place affected may be likewise fomented, and throughly washed, and afterward a *Magma* or sweet Confection may be applied in the form of a Cataplasm.

The other way of curing the Cancer is that that we cal a Counterfeit or Palliative Cure; by which we only use our endeavor that the Cancer may not be augmented and get any further growth; and that the pain thereof may be asswaged; that so the sick Person may lengthen out, and lead the remainder of his life with the less excruciating and afflicting misery. Such Medicaments are those that do not putrifie, neither corrode and bite the part, but do moderately dry and cool it; and they are such as are above mentioned; and more of them you may likewise see in the fourth Book of our Practise, Sect. 3. Part 1. Chap. 7.

Lupus *or the Wolf, and* Noli me tangere.

There may be referred unto a Cancer (or at least, certainly, thereunto subjoyned) those Tumors or Ulcers which they vulgarly call, *Noli me tangere*, and *Lupus*, the Wolf.

Now some there are that divide the Cancer into three Species or kinds; into the Cancer that is by the Greeks & Romans absolutely and specifically so called, and which is commonly and wel known by that name; into the *Noli me tangere*, and the Wolf. And they then only term it *Noli me tangere*, when there ariseth a Tumor or Ulcer upon the Chin, and especially about the Mouth and Nose, bearing a resemblance with, and being very like unto an exulcerated Cancer, growing and increasing very slowly at the beginning; which (as *Theodoricus* truly telleth us) continueth for one whol yeer no bigger than a Pustule, and is as it were a very smal and inconsiderable Push; and which afterwards and at all times creepeth less than the Cancer: and *Rogerius* in his fifth Chapter writeth, that the Cancer doth corrode more in one day, than *Noli me tangere* doth in a Month. And it is so called, either because it ought not to be rubbed (since the more it is handled and rub'd the worse it becomes) or else in regard that it is a Contagious Malady; or else lastly, because it is rather exasperated then mitigated by Remedies, and is thereby caused to creep into the sound parts.

But they cal it *Lupus* or the Wolf, if it be in the Shins, Ankle-bones, and Thighs. But in all other parts of the Body, although it retein stil the same pravity and malignancy, they conceive that it is not to be absolutely called *Lupus*. Yet notwithstanding (when it ariseth and appeareth in the midst of the Body) others term it *Cingulus*, a Girdle; as *Guido* tels us in his Serm. 7. Tract. 4. Summ. 1. Chap. 24. but it is so named by reason of its vehement corrosion, and eating through. The vulgar People likewise wil have it to be from hence so called, to wit, because like unto a hunger-starved Wolf it consumeth the Flesh of Hens, yea and other flesh also. This Opinion is indeed by *Joh. Philip. Ingrassias* exploded, and termed a fatuity and vain foppery. But that some such thing there is done, is related and asserted by divers, and it is confirmed by the History that *Mauritius Cordæus* relateth in his first Book, Comment. 7. upon *Hippocrates*, touching Women. *There was* (saith he) *a certain Noble and Choice Woman, living nigh unto the Castle of* Nenve, *that had all the right side of her Face possessed and overspread with a* Cancer, *and that likewise exulcerated of a long time, insomuch that her Face was most grievously tortured with pains and griefs of all sorts. She having in vain and to no purpose at all sought for help unto the Physitians, as wel French and Italian, as Spanish and Germans (together with other forreign Physitians) was at length perfectly cured by this following expedite and speedy Remedy that she had learned of an ordinary and vulgar Barber Chirurgeon. She cuts Chickens into very smal and broad pieces, the which she dayly applied unto the part affected, oftentimes changing and renewing them: and at length by this one only Remedy she recovered her former perfect health and soundness.*

Menardus (in his seventh Book, Chap. 1.) referreth the Tumor *Lupus* or Wolf, and likewise the *Noli me tangere*, both of them to the Tumor *Phagedenæ*.

Chap. 21. *Of a Watry Tumor.*

THere arise in like manner from a Watrish and wheyish humor divers kinds of Tumors; and from this humor it is, that somtimes certain parts of the Body, and somtimes again the whol Body is caused to swel up; of this nature and kind, are the Dropsie, *Hydrocephalus* or Head-Dropsie, Dropsie of the Lungs and Chest, *Hydromphalus*, *Hydrocele*, Dropsie of the Womb, &c. touching all which having already treated in their proper places, we wil here speak somwhat only in general concerning a watery Tumor.

The Causes.

The Cause (to wit, the next and immediate) of watry Tumors, is the collecting or gathering together of a watry or wheyish humor in some one or more parts. But now from what causes these watery & wheyish humors proceed and come to be gathered together, we have already declared where we treated of the *Hydrops* or Dropsie. Now for the place, the watry and wheyish humor is collected in some part that is loose, or that hath in it a Cavity or hollowness.

Signs Diagnostick.

These watery Tumors are soft, lax or loose, and without pain. If they be pressed and thrust down, the print of the finger that maketh the Impression doth not remain: and if we view them wel either by day-light, or Candle-light, they appear transparent, and such as may welnigh be seen through.

Prognosticks.

1. The very watry Tumors themselves that are fomented and cherished by some vice or default in any of the Bowels are not at all dangerous.

2. But those that have their original from somthing amiss either in the Liver, or in the Spleen, although they are not in themselves dangerous, yet they do notwithstanding threaten danger, in regard of the Bowels that are ill affected.

3. Although watry Tumors are not dangerous; yet notwithstanding they are not easily cured, since that the humor is hardly or not at all to be concocted, and is likewise discussed very slowly.

The Cure.

That so the Cure may rightly be performed, the the watry humor which causeth and cherisheth the Tumor is to be evacuated and emptied forth; and speciall care must be taken that no more of it be generated in the Body for the future, and the humor it self that is in the part affected is to be evacuated.

In the first place therefore, the watry and wheyish humors are to be evacuated by Stool, by Urine, and by Sweats; and we must likewise so order it, that the *Diaphoresis* and insensible transpiration may be free and uninterrupted.

Secondly, If there be present any fault in any Bowel that is by Nature destin'd and ordained for Concoction (by which this watry humor is supplied) this is to be corrected; and of this we have already spoken in its proper place.

Thirdly, The watery matter (the next and conteining Cause of the Tumor) is to be evacuated; which is to be performed, either insensibly by those things that Resolve and digest, and dry much; or else sensibly, by opening the Tumor, and pouring out the Matter. Those things that Resolve, Discuss, and dry up the watry humors, are, Rue, Wallwort or Danewort, Elder, Camomile, Dill, the Flower-de-luce root, Aristolochy or Birthwort, Laurel berries, the Meal of Beans, and of the bitter Vetch *Orobus*, Ashes, Salt, Sulphur, Ammoniacum, and Bdellium. As,

Take *Leaves of Rue, of the Elder Tree, and Wallwort, the Flowers of Camomile, of each one handful; Lawrel berries two ounces; boyl them in Ley and Wine, for a Fomentation.* Afterward.

Take *Sal Nitre half an ounce, Sulphur three drams, the Pouder of Lawrel berries one ounce, Ammoniacum half an ounce, Oyl of Rue and Wax, of each as much as will suffice; and make a Liniment.*

But if the matter cannot be discussed and scatterred, then let the Tumor be opened, and the mater emptied forth.

The Diet.

Let such a Diet be ordained and appointed that may not in the least make any supply, or add unto the watry humors; and let it have regard unto the Causes of the collection of the watry humor; touching which we have also already spoken in its proper place.

Chap. 22. *Of* Exanthemata, Ecchymata, Papulæ, Pustulæ, Phlyctenæ, *and* Eczesmata.

BUt now it is very rare (and a thing that but seldom happeneth) that one only humor should excite and cause any Tumor whatsoever; but for the most part, many humors mixed together, and especially the Cholerick, Salt, and serous or wheyish humors, meeting together (and somtimes also black Choler) do excite and produce divers sorts of Tubercles or small Tumors; of which we intend now to treat; and here in the explanation of their several names, we meet with much difficulty. And first of all, *Exanthemata*, and *Exanthesis* (that is to say, Effloreſcences) are so called, in regard that like unto Flowers they break forth in the Skin. *Hippocrates* 3. Epid. Comm. Text 51. calleth them likewise *Ecthymata*, from the Greek, because they impetuously break forth, as *Galen* in his Comment upon *Hippocrates* explaineth it. *Pliny* (in his Book 24. and Chap. 4. and Book 26. Chap 11.) calleth them *Eruptiones*. But now the name [*Exanthemata*] seemeth to be a general name; so that it may comprehend under it whatsoever of its own accord breaketh forth in the Skin; neither indeed is there any certain and particular species of those Tubercles or smal Tumors, whereupon it is that they are likewise called *Exanthemata Sublime* broad,

Exanthemata.

broad, red, round, smal, *Exanthemata* of sweats, *Elcode*, by *Hippocrates* in his third Book of Aphorisms, Aphor. 20. But whether or no there be any general Latin word that may answer unto this *Exanthemata* of the Greeks, I very much question. We indeed meet with the name of *Papulæ*, and *Pustulæ*, that is to say, Wheals, Blisters, Measels, and Pushes. But now whereas there is a twofold sort of *Exanthemata*, one that which only changeth the color of the Skin (as it is wont to be in those Feavers that we cal *Petechiales*;) and another, in which there are certain Tubercles breaking forth in the Skin, the name of *Papulæ* and *Pustulæ* seemeth not to agree with, and answer to both of them, but only unto the latter sort of the *Exanthemata*; for *Papulæ* and *Pustulæ* signifie only Tubercles in which there is some certain humor contained. And yet notwithstanding we find that the name of *Papulæ* is a more special name; and that it seemeth not to be used by *Celsus* and *Pliny*, in one and the same manner. For by *Pliny* the hotter sort of *Exanthemata*, and which are elevated higher than ordinary into a sharp-pointed head, are termed *Papulæ*; of which notwithstanding seeing that there are many differences (viz. red, hot, black, *Papulæ* of sweats) this name seemeth to be general enough. But now with *Celsus* the name *Papulæ* is a special and peculiar name, and signifieth only that affect which the Greeks cal *Lichenes*, and the Latines *Impetigo*. For thus he writeth (in his fifth Book, and 28. Chapter) That the *Papulæ* by the smalest sort of Pustules do exasperate the Skin, and likewise that they corrode and creep forward but slowly; and that where the Disease beginneth round, there it also proceedeth after an Orn-like and round manner; and that that which is less round is more difficultly cured; and that (unless it be taken quite away) it turneth into the *Impetigo*. For he maketh two species of *Lichenes*, as the Greeks likewise do. One he termeth *Agria*, that is, wild; the other more mild; and that the wild *Papula* is cured by rubbing it with fasting Spittle. All which things before mentioned agree with the *Lichenes* of the Greeks.

The name likewise of *Eczesmata* seemeth to be general. For although some by these *Eczesmata* understand only *Hidroa*, or *Sudamina*; and others refer them unto the Head alone; yet without al doubt this name is general, and signifieth a Pustule, or very hot *Papula*, as the name it self importeth.

Of the Tumors Phlyctænæ.

But that we may treat of these in their several species or kinds; the first in order to be handled are those we cal *Phlyctænæ*. Now they are called *Phlyctænæ*, *Phluctides*, *Phluzacia*, and *Phlusis* (from two Greek words that signifie to Boyl or become fervent hot) being Pustules, and little Bladders, excited and caused by the humors when they are as it were boyling hot, and most sharp; like unto those Pushes and smal Bladders that are raised by the fire, and scalding hot water. By others they are likewise named *Ignis Silvestris*, or wild fire. The Arabians cal them *Sabafati*. And indeed these kind of Pustules and little Bladders very frequently break out in the Skin, or rather in the Scarf-skin; and sometimes privily in the *Cornea* Tunicle of the Eye; touching which we have already spoken in the first Book of our Practice, Part 3. Sect. 2. Chap. 17. They oftentimes arise in the Thighs; and in Infants they sometimes break forth in their whol body; but seldom so in men.

The Causes.

The *Phlyctænæ* proceed from a Cholerick and extream hot humor, mingled together with a humor that is salt and wheyish. But now from what Causes such like humors are generated, we have elsewhere declared. They sometimes likewise befal women, by reason of their Menstruous blood over long retained and corrupted. But now those Humors are called forth unto the Skin, when any one having been in the cold suddenly approacheth neer unto the fire, or else betaketh himself to a hot Bath; and so on the contrary, when after heat the pores of the Skin shal be altogether close shut up by the external cold.

The Signs Diagnostick.

The little Bladders that resemble those that are raised by the fire or scalding hot water do suddenly break forth; and when they are broken, there issueth forth by little and little a yellowish humor: the Crusts thereof wax hard, and then they fal off. By reason of the acrimony and fervent heat of the humor they excite an itching in the Skin.

Prognosticks.

1. *Phlyctænæ* (as *Aetius* tels us, Tetrab. 4. Serm. 2. Chap. 63.) abide and continue sometimes for two or three daies.

2. *Phlyctænæ* if they be not wel and rightly cured, they now and then degenerate into an *Herpes*.

The Cure.

If such like vitious humors abound in the body, then (in the first place) such a kind and course of Diet is to be prescribed that wil not encrease those like Humors, but such as may rather correct that Cacochymy. And moreover, the said vitious Humors are by convenient Medicaments to be evacuated.

Now as for Topicks, let the *Phlyctænæ* first be fomented with the Decoction of Lentils, Myrtle, and Pomegranate Rinds. Or,

Take *the Mucilage of Fleabane or Fleawort*

seed, Rose water extract six ounces; the Juyce of Purslane, and Nightshade, of each two ounces: mingle them, and let the place affected be anointed therewith.

If they break not of their own accord, and thereupon cause a grievous pain, they are then to be prickt and pierced through with a needle; and the Pustules are to be hard squeezed; and upon the Ulcer lay this following Cataplasm:

Take *Barley Meal, the Meal of Lentils, and of Beans, the pouder of Pomegranate Rinds, of each an ounce; with a sufficient quantity of the Oyl of Roses make a Cataplasm.* Or,

Take *the Leaves of Plantane, Mallows, Myrtle, of each one handful; boyl them to a softness, and pass them through a hair sieve; then add unto them Barley Meal, the Meal of Lentiles, and crums of white Bread, of each as much as will suffice, and make a Cataplasm.*

Or else let a Liniment made of Swines Fat, with the Spume or Froth of Silver, in a Leaden Mortar, be laid on. Or,

Take *Juyce of the Root of sowr Sorrel, and Scabious, of each two ounces; Oyl of Roses four ounces; the Fat of an old Hog six ounces; boyl them until the Juyces be consumed; and afterwards add Litharge of Gold one ounce; live Sulphur six drams; Turpentine half an ounce; stir them wel together in a Leaden Mortar, and make a Liniment.* Or,

Take *Litharge, live Sulphur, Myrtle Pouder, of each one ounce; stir them wel together with Vinegar in a Leaden Mortar; and adding thereto a sufficient quantity of the Oyl of Roses, make an Unguent.*

See more of this in *Aetius*, Tetrab. 1. Serm. 4. Chap. 21.

Chap. 23. *Of* Vari *or Pimples.*

Vari are Tubercles or little Swellings somwhat neer of kin unto *Psydracia*, by the Greeks called *Fonthoi*, because that like unto Dung they are the defilement and the disgrace of the Countenance, by fouling and disfiguring of the Face. *Galen* in his second Book of the Method of Physick, Chap. 2. reckons up these among those names that neither represent the place affected, neither the cause that produceth them. They are likewise by some named *Acne* or *Acna*, as *Aetius* tels us, Tetrab. 2. Serm. 4. Chap. 13. Although *Hermolaus* in his Gloss upon *Pliny* reads the word *Acmas*, as if this kind of Affect were commonly so termed by the Greeks, in regard that it is wont to seize upon those that are of ripe and ful age. *Celsus* in his fifth Book, Chap. 6. writeth thus: *It is almost but a meer folly* (saith he) *to attempt the curing of these* Vari *or Specks, and Pimples in the Face, or the little Pushes and beat-wheals of the same. But* Vari *and Lenticulæ or Pimples, are very wel and commonly known: and yet notwithstanding you cannot possibly take from Women the care they take in tricking themselves up, and especially in trimming their Faces.* In *Galens* Opinion (as we have it in his fifth Book of the Composition of Medicaments according to the place, Chap. 3. and in his Book of making those Remedies that may be provided, Chap. 51.) *Fonthos* is an hard and little swelling in the Skin of the Face, raised from a thick Juyce that is there gotten together. The which in regard that it is altogether void of the wheyish moisture, it is therefore not at al itching, neither doth it require or stand in any need of scratching.

This Humor is for the most part alimentary, insinuating it self into the Pores of the Skin. But yet there is likewise oftentimes therewithal mingled an excrementitious Humor, and atrabiliary blood.

Signs Diagnostick.

We have before told you out of *Celsus*, that this Tumor is sufficiently and commonly known.

Prognosticks.

1. This Affect hath in it no danger; so that *Celsus* thinks it meer folly so much as to will or desire the Cure of this Tumor.

2. Those *Vari* that arise only from the thicker and grosser Aliment, are firm and stable. But if an Excrementitious Humor be mingled with them, the Tubercles pour forth an Ichor or thin Excrement; and if they be suppurated they turn into Ulcers.

3. If together with the Pushes there be an Intense and extraordinary redness in the face, the Malady is then very hard to be cured, if not altogether impossible: and although the Pustules may be removed by strong Medicaments, yet the redness wil notwithstanding remain, and encrease unto a higher pitch.

4. When there is a redness conjoyned with the swelling and puffing up of the Face, and a hoarsness of the voyce, this is a very shrewd sign of an approaching Lepra, or Leprosie.

The Cure.

These Tubercles are to be cured by Emollients, Discussers, and likewise (unless they in a short time yield and give place) by corroding Medicaments. As for instance,

Take *Meal of Lupines, of the bitter Vetch Orobus, of each one ounce and half; of Mallows peeled, and Flowerdeluce Root, of each two drams; Salt Ammoniack one dram; with Mucilage of Gum Tragacanth make Trochisques, which at the time of using them may be dissolved in Milk.* Or,

Take *Honey, and the sharpest or sowrest Vinegar, of each one ounce and half. Mingle them.* Or,

Take

Take *Litharge of Gold three drams*; *Turpentine half an ounce*; *common Oyl as much as will suffice*: *mingle them.* Or,

Let the Face be anointed in the Evening with bitter Almonds wel pounded and made into a Mash, and so mingled with Vinegar; and in the morning wash the Face with Milk.

If the *Vari* be harder than ordinary,

Take *Black Soap half an ounce*; *Ammoniacum, Frankincense, of each a dram and half*; *let them be dissolved in Water, that they may get the thickness of a Cerote.* Or,

Take *the Juyce of the sharp Dock two ounces*; *Vinegar of Squils half an ounce*; *Gum Ammoniack dissolved in Vinegar two drams*; *Borax a dram and half*; *Allum half a dram*; *mingle them, &c.* Or,

Take *the Root of sowr Sorrel, and Elecampane cut into smal pieces, of each one ounce*; *Hyssop and Penyroyal Leaves, of each half an ounce*; *boyl them in Vinegar until they be soft and tender, and then bruise them very smal. Add hereto of soft Soap half an ounce*; *Ammoniack dissolved in Vinegar two drams*; *Myrrh, Frankincense, Borax, of each half a dram*: *mingle them.*

Chap. 24. *Of* Sudamina, *and* Sirones.

SUdamina (which the Greeks cal *Hidroa*, and likewise *Exanthemata*) are with us those Efflorescences or Pushes, or Wheals that stick and have their residence in the utmost Skin of the body, like unto the grains of Millet, that by their exulceration do exasperate the Skin. Some there are that wil likewise have them to be called *Ecxesmata*. By *Pliny* in his third Book, and Chap. 4. they are termed *Papulæ Sudorum*, or sweating Pustules. *Rhases* and *Avicen* name them *Asef*, or else (with the Article) *Alasef*, or *Hasef*, and *Alhasef*. It is an Affect that is very common and familiar unto Children and yong persons (especially those that are of a hot temperament and constitution, and such as in the hot Summer time use overmuch motion and exercise) happening and arising in the Neck, Shoulder-blades, Breast, Arms, and Thighs; but yet notwithstanding more frequently neer about the privy parts, and the Fundament or Arse; whereupon it is that *Hippocrates* in the third of his Aphorisms, Aph. 21.) reckons it up among the Summer Diseases.

The Causes.

Now these *Sudamina* have their original from the many Cholerick and sharp biting sweats that corrode the Skin, and cause a roughness or ruggedness therein, exulcerate after the manner of Ulcers, and excite in the said Skin a certain kind of itching. And they arise more especially in a hot and moist Summer, after the use of those things that are hotter and sharper than ordinary, extream labor and pains, from inhabiting in a place hot and moist, a wind not sufficiently piercing and purifying, overgreat and excessive sweats; and lastly, the filthiness and nastiness of the Apparel.

Signs Diagnostick.

These Tubercles are sufficiently manifest. For in the Skin there appear a roughness, and itching Pustules.

Prognosticks.

The Affect is not in the least dangerous; but for the most part is cured by the help and strength of Nature, without the use and application of any Medicaments.

The Cure.

And therefore let the Patients wearing Apparel be sweet and clean, and let him often shift himself.

If the Affect be mild, gentle, and moderate, it is then cured by only washing with Rose Water, or Plantane Water; unto which notwithstanding there ought to be added a grain or two of Camphire.

But if it be more grievous, and if that Cholerick Humors abound in the Body, they are to be altered and evacuated.

Afterward this Bath is to be made use of:

Take *the Root of sowr Sorrel, and white Lillies, of each half a pound*; *Briony three ounces*; *of these Herbs following*, viz. *of Mallows, Violets, Marsh-mallows, Pellitory of the Wall, Bears-foot, of each one handful*; *Fumitory three handfuls*; *the flowers of the Water-Lilly, Red Roses, and Beans, of each one handful*; *Bran two pound. Boyl them in pure and sweet Water for a Bath.*

After the Bath, if there be occasion let this Unguent be administred:

Take *Oyl of Violets, of Roses, of the Water-Lillies, or as some cal it, the Water-cress, of each half a pound*; *Juyce of* Lemmons *three ounces*; *Litharge one ounce*; *Cerus or white Lead half an ounce*; *Camphire one dram*; *let them be wel stirred together in a Mortar, and make hereof a Liniment.*

Sirones.

Hither likewise belong those Pustules that the Germans cal *Seuren*, that arise either in the hollow of the Hand, or on the soles of the Feet, or both, in the which there lieth hid and secret an exceeding smal sort of Worms under the Scarf-skin, which they term *Sirones*, or *Chirones*. Now the Affect ariseth chiefly in these places, because that the more thick and gross *Ichores* or ulcerous Excrements are in every scabbiness detained and held

held under the Skin which in the aforesaid place is more thick than elsewhere.

Signs.

We may know whether or no these Worms lie hid in the Pustules, if the itch that is here felt be greater than that which is wont to be (at other times) perceived in these places.

These *Chirones* are (for the most part) digged forth with the Needle; and after this (that so they may not be bred anew) the place is to be wel washed with Wine or Vinegar, in which Salt, Alum, or Nitre hath been dissolved; or else with a Ley that is made of the Ashes of Broom Sprigs, or the Boughs of the Oak Tree. After it hath been washed and throughly dried again, let it be anoynted over with this Unguent following, *viz.*

Take the sharp Dock (or as some call it, sowr Sorrel) Scabious, Wormwood, Tansey, the Leaves of Peaches, of the Ash tree, of Henbane, and of the Walnut, of each one handful; let them be al wel and throughly bruised together; and together with those Juyces, take of the Fat or Lard of an old Hog, two pound let them boyl all together until the Juyces be consumed: and afterwards add of Ship Pitch one pound and half; and let the whol be streined through a Cloth; and then,

Take *Myrtle, Frankincense, Mastick, of each two ounces; let them be poudered very smal; and let them be put into the streining; and then let them be moved and stirred about with a Spatula until they have the likeness and consistence of an Unguent.* And whensoever there is any occasion to make use of, and to do and act any thing herewith, then unto six ounces of this Unguent we may add one ounce of Quick-silver, extinguished and killed with fasting Spittle, or shaken together with the white of an Egg, and by this means you may Cure within fifteen daies all kind of Scabbiness whatsoever it be of this Nature, or those *Sirones* that are accompanied with an itching. And thus much may suffice to have been spoken touching these Tumors (or rather Tubercles) *Sudamina* and *Sirones*.

Chap. 25. *Of* Epinyctides, *and* Terminthi.

Epinyctis is so called, because it ariseth in the Night; as *Galen* (in his second Book of the Method of Physick, Chap. 2. and *Celsus* (in his fifth Book, and 28th Chapter) hath informed us. Yet notwithstanding *Paulus Ægineta* (in his 4. Book, Chap. 9.) and *Aetius* Tetrab. 4. Serm. 2. Chap. 61. conceive that they are so called, not because it ariseth in the night, but because in the night time it doth more vehemently excruciate and torment the Party thus affected. But both these reasons may very wel stand together, to wit, that this Tubercle ariseth by night, and that it doth likewise in the night time most grieve & excruciate the Party affected therewith. *Paulus Ægineta* therefore, and *Aetius* (in the places alleadged) define the *Epinyctides* to be small Ulcers breaking forth of their own accord, like unto *Phlyctænæ* or Blisters, somwhat reddish, which being broken there issueth forth a bloody filth and matter. They do not greatly excruciate the Party in the day time; but by night they torture and torment him with a pain that is more then usual in an Ulcer. But yet, although *Paulus* and *Aetius* define *Epinyctides* by litele Ulcers; yet notwithstanding without all doubt they understand Pustules degenerating and turning into Ulcers. Neither are they generated only of Cholerick and bloody filth and corruption, but likewise from other humors also. And therefore *Pliny* in his Book 20. and Chap. 6. calleth them pale and wan Pustules, and such as disquiet in the night time. But *Celsus* in the place alleadged doth most cleerly and plainly describe them, in these words; *It is* (saith he) *the worst of all kind of Pustules, that is called* Epinyctis. *It is wont to be in colour either somwhat pale and wan, or somwhat black, or else white. About this there is also a vehement Inflammation, and within there is found a snotty and nasty exulceration. The colour is like unto its humor from whence it ariseth. The pain that it causeth is greater than its bigness, and transcendeth its magnitude, for it is no bigger then a Bean. And it likewise ariseth in the eminent parts, and most commonly in the night time; for which cause it hath this name* Epinyctis *imposed upon it by the Greeks.*

There are some that conceive these *Epinyctides* to be *Essere* of the *Arabians*; but they are mistaken, as it wil appear by the Chapter following; for *Essere* (unless it be very much scratched and clawed) poureth forth no humor at all.

The Causes.

The Causes of this Tumor are a Salt and wheyish humor, and Flegm, together with which there is sometimes mingled some of the Blood, and Cholerick *Ichor*, and now and then likewise some of the black Choler. From whence also it is that the colour is not alwaies one and the same, and by reason of the Flegm therwith mingled the Pustule being opened there is found within a certain snotty and filthy exulceration. And the Tumor is almost if not altogether such as that which causeth the Carbuncle, but only that there is here no malignity present; neither is the Tumor likewise here so great as it is in a Carbuncle; neither is it (as we told you out of *Celsus*) bigger then a Bean. But that it is more exasperated by night, the Cause hereof is a black humor (that is wont to be moved more in the night) and the nocturnal cold, which shutteth and closeth up the Pores of the Skin.

Signs

Signs Diagnostick.

It is not at all needful that we declare the signs and tokens of this Tumor; since that it may be sufficiently known from the aforementioned description of *Celsus*.

The Prognostick.

To tel you the truth, these Tubercles are not dangerous; and they denote the strength of the expulsive faculty: yet notwithstanding they are very grievous and troublesome by reason of the pain they cause; and they bring restlessness likewise upon the Party in the night time, and they signifie that an adust and vitious Juyce doth superabound in the body.

The Cure.

And therefore the naughty and vitious humor is to be evacuated; and if the blood too much abound, a Vein is then to be opened; and withall there is such a kind of Diet to be prescribed that may not generate and breed an adust humor.

As for Topical Remedies, such a like Bath, or Lotion, may be appointed, *Viz.*

Take *Mallows, Violets, Pellitory of the Wall, Bearsfoot, of each three handfuls; Nightshade one handful; Marshmallow seeds, and the four cold seeds wel bruised, of each one ounce; boyl them in sweet water, for a Bath.*

Paulus and *Aetius* commend the liquor of *Laserpitium*, with salted water, in regard that it drieth without any corrosion at all; as also the Leaves of the Hemlock or Henbane bruised and pounded smal together with Honey; as likewise the Green Coriander, and Nightshade bruised and mingled together; or the Leaves of the Wild Olive bruised. For those Ulcers that spring and arise from Pustules, this following Medicament is very proper and convenient;

Take *Ceruß half an ounce, Litharge one ounce and half; Fenugreek seed half an ounce, Roses two drams, the Juyce of Endive as much as wil suffice; let them be mingled and stirred together until they attain unto the thickness of Honey, or a Liniment: but let there be a careful abstinence from whatsoever is sharp, acid, and salt.*

Terminthus.

Some there are that refer likewise *Terminthus* unto these *Epinyctides*. But it doth not yet sufficiently appear what this Tumor *Terminthus* of the Ancients is properly; but only what we have from *Galen*, who in Epidem. 6. Comment 3. Text. 37. thus writeth; that the name of *Terminthi* doth signifie certain black Pustules, arising especially in the Thighs, derived from the likeness and resemblance they have in figure, colour, and bigness with the fruit of *Terminthi*, that is *Cicers*, (as they vulgarly render it; but as others, and that more rightly, the fruit of the Turpentine Tree.)

Chap. 26. Of Essere.

THere is also a certain kind of Tumor (which we but very seldom meet with in the writings of the Greeks and Latines; but oftentimes mentioned by the *Arabians*, and now & then likewise by the Physitians of our own time, such especially as live neer us in our own Country) which they cal *Essere*, *Sora*, and *Sare*; to wit, when little Tubercles, inclining to a red colour, and somwhat hard, do suddenly and unexpectedly seiz upon the whol Body, together with an extraordinary & troublesom itching; Just as if the Party had been bitten and stung by Bees, or Wasps, or Gnats, or stung with Nettles; and yet notwithstanding so that after a long time they vanish again; & the Skin likewise (without the issuing forth of an ichorous excrement, or any other moisture whatsoever) recovereth its former smoothness and colour. There are some indeed that refer these kind of Tubercles unto the aforesaid *Epinyctides* of the Greeks; but they are herein mistaken. For *Epinyctides* and *Essere* are Tumors altogether differing one from the other; in regard that *Epinyctides* pour forth out of them a certain humor, which *Essere* doth not, but vanisheth without any kind of humor issuing therefrom. Moreover the *Epinyctides* (according to the name they have thereupon Imposed on them) do afflict and grieve the Patient most of all in the night time; but the *Essere* very rarely break forth in the night, but (for the most part) in the day time. The way and Method of Curing them is likewise very various and different.

It is somwhat doubtful whether or no this kind of Tumor was at all known to the *Grecians*; since that we meet not (in any of their writings) with the true and proper kind of this Tumor; neither do they make any the least mention hereof; unless haply there be any that will refer this Tumor *Essere* unto *Exanthemata* that are without any Ulcer.

Serapio in the fifth of his Breviary, and Chap. 8. maketh a twofold sort of this Tumor, differing according to the Nature and quality of their Causes. The one he deriveth from cholerick blood; the other from a salt and nitrous Flegm; but this more rare. Others there are that assert that this kind of Tumor doth arise from an exhalation or vapour of hot fervent Blood, or else the admixture of the Cholerick and Salt humors.

The Causes.

Whosoever knoweth and understandeth the Nature of serous wheyish humors wil not deny that such like Tubercles may possibly be excited from serous or wheyish humors, being such as are sharp and easily moved, and likewise such as without much ado vanish and are discussed. Which appeareth, and may be confirmed even from hence, that

that this Malady may be, and is removed especially by Venesection or blood-letting, which said Venesection doth chiefly and principally qualifie and allay that extream and fervent heat of the serous and wheyish part of the blood. Yet notwithstanding the itch that is somtimes greater, and somtimes less, likewise teacheth us, that there is not one alone difference of this wheyish humor; but that somtimes this said whey is more mild and moderate, and somtimes again more sharp and hot; somtimes thinner, and somtimes thicker; as likewise thus much (which I my self have very often observed) that these Tubercles (while the the Patients are in a hot place) they then break forth and appear, and that when they expose themselves unto a cold Air, the *Effere* then vanish; and as soon again (on the contrary) to bud forth in the cold Air, and to vanish in a hot place: the former whereof seemeth from hence to happen, to wit, because the humor is very thin and moveable, and therefore is instantly driven in again by the cold ambient Air; but the latter, because the Humor is not altogether so movable and thin, but somwhat more thick, which for that very cause cannot transpire in a cold Air; but in a hotter Air it wil transpire or breathe through.

But this wheyish and thin Humor is for the most part generated from the fault of the Liver; which from some preternatural cause is disposed to generate and breed this humor. Now that said Humor waxeth extreamly hot from the Causes Procatartick (as they cal them) that stir and move the blood. And this happeneth likewise in the Winter time, and in cold Regions, rather than in hot.

Signs Diagnostick.

It is easily known by those notes and marks that are above mentioned; to wit, there somtimes goeth before an Ulcerous Lassitude; and then there break forth in the whol body itchy Pustules; as if the party had been pricked by Bees, or stung with Nettles.

The Prognosticks.

1. These Tubercles vanish of their own accord within a very short space, although there be no course taken for the curing of them; and they are not suppurated; neither doth there issue forth of them any humidity at al. And if this should somtimes so happen, yet this chanceth rather by reason of the scratching of them, and also from the vehemency of the Itch (which is extream troublesom to the sick persons) than by means of the Tumor.

2. Somtimes these *Effere* go before Cholerick Feavers; and therefore such as are very frequently molested and grieved with these Tubercles ought not in any case to neglect the Cure, left that they fal into Feavers, and some more grievous Disease.

The Cure.

For the most part, there is no need at al to administer Topicks; but if the fervent heat of the Blood and Humors be (by Venesection and the administring of Medicaments that alter) qualified and kept under, the Tubercles wil then soon vanish, and the smoothness and Natural color will forthwith return unto the Skin. To wit, in the first place a Vein is to be opened, and so much of the blood drawn forth as the state and condition of the body requireth. And afterwards, if there be any need at al thereof, the Cholerick and wheyish Humor is to be drawn forth by Tamarinds, Myrobalans, Rheubarb; afterward let there be administred the Juyce and Syrup of Pomegranates, Ribes, Syrup *de Agresta*, of Varjuyce, Whey; with the Emulsion of the four cold seeds, and the like; Milk tart and sowr, &c. It is likewise very requisite to put the sick person into a Bath of warm Water.

Let his Diet likewise be cooling and moistening.

Chap. 27. *Of* Scabies, *or Scabbiness.*

Scabies or Scabbiness ariseth likewise from adust matter, as doth also the Itch; that is (as it were) a certain *Præludium* and forerunner of Scabbiness, and the like Affects. Now *Scabies* by the Greeks and Latines is called *Psora*, an Affect sufficiently known; in the which there is not only present some kind of foulness and deformity of the body, but a distemper also even of the very Skin, together with a swelling and exulceration; from whence it is, that the actions of the Skin are likewise hurt. But more especially, in the *Scabies* or Scabbiness, the top and utmost part of the Skin is affected; insomuch that out of it (as *Galen* tels us in his fourth upon the Aphorisms, and the 17. Aphor.) there is some such like thing cast forth, that beareth a likeness and resemblance with the casting of Serpents. From whence it likewise differeth from the Itch: for in the Itch there is only a roughness of the Skin, in which there is nothing that fals off notwithstanding the scratching; whereas in the *Scabies* there is not only a roughness of the Skin, but likewise a distemper with a swelling; from which (by scratching) the bran-like bodies are easily and readily separated; and together with them divers *Ichores* likewise, and filthy purulent Excrements.

The Causes.

But what the Cause of the *Scabies* is, in this Authors seem not so wel to agree. *Galen* in his Book of Tumors, Chap. 1. & 3. tels us that *Scabies*

bies alſo, and *Lepra* are Melancholick Affects; and likewiſe in the ſeventh Sect. Aphor. 40. that *Cancers*, *Elephantiaſes*, *Lepra's*, and *Pſora's*, are al of them Melancholy Affects; and the ſame he alſo tels us in other places. But *Avicen* in the ſeventh Book of his fourth Tome, Tract. 3. Chap. 6. writeth that the matter of *Scabies* is the blood; with the which Choler is mingled, and that converted into Melancholy or ſalt flegm: and with him the other Arabian Phyſitians agree. But the very truth is, that although in the *Scabies* the humor be not alwaies one and the ſame, yet in every *Scabies* there is ſome kind of mixture of the aduſt and melancholy, hot and dry humor. And furthermore, there is one ſort of *Scabies* that is moiſt, another that is dry. The moiſt, in the which there floweth forth a certain matter that is moiſt, and withal rotten, filthy, and purulent; but the dry is that in which there is but little or none of the aforeſaid matter caſt forth. And concerning this latter it is that *Galen* ſeems to ſpeak, as being ſuch wherein that melancholy humor doth more ſuperabound. But *Avicen* and the reſt of the Arabian Phyſitians underſtand hereby al kind of *Scabies* whatſoever. Now albeit the next cauſe of *Scabies* be a humor ſharp and ſalt; yet notwithſtanding *Avicen* doth not altogether abſurdly aſſert that blood is the matter of the *Scabies*. For ſeeing that *Scabies* is an Uniververſal Affect of the whol Body, it cannot therefore eaſily proceed from any other humor, unleſs that blood be likewiſe therewith mingled; and yet notwithſtanding the blood cannot properly be ſaid to be ſimply the cauſe of *Scabies*; to wit, ſo long as it retaineth its benign and temperate Nature. For whileſt it continueth benign and good, it can in no wiſe excite and cauſe the itching, neither yet thoſe Ulcerous Tumors or Swellings. Wherefore, before ſuch time as the blood can poſſibly produce and breed the ſaid *Scabies*, it muſt of neceſſity be corrupted, and other humors that are ſharp and biting therewith mingled. And true it is indeed, that yellow Choler is ſharp and corroding, but then it ſcarcely floweth in ſo great abundance, or is of that thickneſs as to excite ſuch like Tumors. But black Choler and ſalt Flegm are Humors very fit and moſt apt to produce the ſaid *Scabies*. For theſe Humors being thick, hot and dry, and withal biting and corroding, if they chance to be thruſt forth unto the Skin, there they ſtick faſt in it; and there they excite a hot and dry diſtemper, an itching, a ſwelling, and an exulceration.

But now as for the primitive Cauſes (and more eſpecially for the generating and breeding of thoſe ſalt, biting, and ſharp humors) the kind and ordinary courſe of Diet that is kept doth exceedingly advance and further the ſame, Meats (to wit) of a bad juyce, and that afford an unwholſom and corrupt aliment; ſuch as are ſalt, ſharp, and that are eaſily corrupted. And hence it is, that the poorer ſort of people (who live upon theſe kind of unwholſom corrupt meats) are moſt frequently infeſted with the *Scabies* or Scabbineſs; as likewiſe Children, and yong people in general, in regard that theſe are altogether careleſs and heedleſs in their Diet; whereupon they contract great ſtore of excrements, that being retained in the outward part of the body are there corrupted, and ſo they get an acrimonious quality. But then from theſe bad and naughty meats thoſe ſharp and ſalt humors are the more eaſily bred if there be preſent a hot and dry diſtemper of the Liver. And hitherunto likewiſe relateth the uncleanneſs and naſtineſs of the body, to wit, when there is altogether a neglect in the keeping it ſweet and clean; and if the foulneſs and impurities of the Skin be not duly waſhed off, or the garments not ſhifted and changed often enough; whereupon it is, that filth and impurities ſticking in the ſuperficies of the body do not permit ſo free a paſſage forth unto the excrements; and by this means the ſaid excrements acquire a certain acrimony, and ſo corrupt the other humors. The *Scabies* ariſeth likewiſe ſometimes after a Criſis, and after Diſeaſes both acute, and thoſe alſo that are of a long continuance; to wit, when Nature expelleth forth unto the Skin thoſe naughty and depraved humors, which it is not able any other way to diſcuſs and evacuate. And laſtly, *Congium* is likewiſe accounted and reckoned up among the principal cauſes of *Scabies*; which cauſe *Galen* alſo acknowledgeth, in his firſt Book of the Differences of Feavers, Chap. 2. and Book 4. of the Differences of Pulſes, Chap. 3. For in the Superficies of the Skin of thoſe that are Scabby there is a certain viſcous and clammy moiſture gathered together, which being either by the Apparel, or by ſome other means communicated to the body, corrupteth the humors therein, after the like manner, and produceth the like Affection, and that eſpecially in theſe bodies that are now already diſpoſed unto the *Scabies*. And indeed the humid or moiſt *Scabies* is the more contagious, in regard that in this there is generated more of the aforeſaid viſcid and clammy humidity.

The Differences.

Some there are that reckon up very many Differences of *Scabies*; as that one is new, another old and inveterate; and that one ſeizeth upon the whol Body, another upon the Hands only, and the Thighs: but the main and ſpecial Difference is that which is taken from the Difference of the Humors; that one ariſeth from a black and melancholy humor, (and this is called a dry *Scabies*) in which although there be a concurrence of other humors, yet notwithſtanding the greateſt part thereof is of this laſt mentioned humor; from whence it is, that out of the parts affected with this *Scabies*, either there is nothing at all ſent forth; or if there be any thing iſſuing out,

it is thick, dry; and the Ulcers themselves, as likewise the prints and footsteps (as we may so term them) of these Ulcers are wan and pale, and sometimes black: another is humid and moist; in which there aboundeth a salt flegm; out of which there plentifully floweth forth much moist filth and corruption, that is thin and subtile, sharp; and now and then likewise it wil be thick.

Signs Diagnostick.

The *Scabies* or Scabbiness, is an Affect very wel known, and it may easily be discerned, (as may also its Differences) and from those signs and tokens especially that we but even now mentioned. And yet notwithstanding those signs do now and then vary, and are something changed, according as the aduction of the other humors is greater or less.

Prognosticks.

1. Now although the *Scabies* be in this respect troublesom, to wit, in regard of the foulness and deformity that it causeth in the Skin, rather than that it bringeth with it, or threateneth any other danger nigh at hand; and that in youth it oftentimes preserveth, and likewise freeth from other Diseases: yet notwithstanding it is not alwaies secure and safe. For if it be of any long continuance, it may (and somtimes doth) turn into the *Lepra* or Leprosie; and in Ancient persons it is contumacious and stubborn, and hard to be cured.

2. And among the several species and kinds of them, the dry is more difficult in curing than the moist. And therefore (whatever kind or sort it be of) it is not at any hand to be neglected; but by a due and fit Cure (even for the very deformities sake, if there were no other cause) speedily to be taken away and removed.

Of the Scabies retiring inwardly.

That *Scabies* that hath its rise and original, not from any contagion, but from some internal default of the humors, for the most part breaketh forth (as it were) critically, and ariseth from some internal vice of some one or other of the Bowels; in which so soon as any vitious humors are generated, they are immediately by Nature thrust forth unto the outward part of the body: the which motion if Nature be not able to perfect and accomplish it; or in case she be by Medicaments administred unseasonably hindered in her operation, divers Diseases are from hence excited. Touching the Quartan we have spoken before, where we treated of Feavers. There are oftentimes other Feavers, (long continued, and sufficiently dangerous) and likewise very often intermingling Feavers; but for the most part, they are inordinate Feavers that arise in this manner, and by this means. Of this I here cured (in the yeer 1636. in the month of *April*) a certain man of a melancholy Constitution; and who had withal likewise a continued Feaver, together with a sore and very grievous Cough, by means of which he cast forth and brought away much Spittle, and somtimes also great store of blood; he was likewise afflicted with a difficulty and shortness of breathing, insomuch that there was now great cause to suspect and fear a *Phthisis* or Consumption. Now having for eight daies made use of Medicaments to very little purpose, I made a further and more strict enquiry into the Cause of the Disease; and then the Patient gave me to understand (which until now he had concealed from me) that before he was taken with this Disease he had the *Scabies* (or scabbiness, as we cal it) the which was no sooner vanished and gone, but this Feaver and Cough followed thereupon. The which I no sooner came to understand, but that I used the utmost of my endeavor, (by Medicaments made of Fumitory, and such like) to cause the Scabs again to break forth. Which I had no sooner effected, and administred such other Medicaments as I thought fit, but both the Feaver and the Cough ceased; and the man is yet living, and perfectly sound, without any the least fear of a Consumption.

Many Diseases proceeding therefrom.

An example of a continual Feaver from the Scabs retiring inwardly.

I have told you elsewhere of a certain Student; this man affected with this *Scabies* (after, and immediately upon the striking in of the Scabs) became instantly blind, and for two daies could see nothing at al; this his blindness was likewise accompanied with an extraordinary streightness of the Breast, difficulty of breathing, and black Urines. This man upon the use of fit and conveniene Medicaments that were administred to evacuate the adust humor (as Fumitory, and such like) within four daies recovered his sight again. The same party (a quarter of a yeer after) being again afflicted with the same Malady did not lose his sight as formerly, but had one fit of the Falling-sickness. But yet notwithstanding, having had fit and proper Medicaments prescribed him, he again recovered.

Another example of blindness from the same cause.

And likewise of the Epilepsie.

I have likewise seen many that from Scabbiness have been surprized and invaded with prickings and shootings in the Breast, with the bastard Pleurisie, and dangerous stitches, and likewise with the *Cachexy*. I knew also a youth (aged fourteen yeers) that upon the unseasonable use of inunctions (against the *Scabies*) made his Urines black, lost his sight; and at length being seized upon by the Epilepsie (and the fits thereof being become very frequent) in the end he died thereof. Wherefore we say that this *Scabies* is no way to be sleighted,

And many other discommodities and inconveniences arising from the same cause.

ſleighted, neither driven inwardly, or up and down; and if it ariſe from any internal vice of the humors, and the Cacochymy, then externall Medicaments are by no means to be adminiſtred before the uſe of Purgers, and other internal neceſſary Medicaments.

The ſame is likewiſe to be taken and underſtood touching the Achores in Infants:

But now what hath been ſaid touching the *Scabies* or Scabbineſs; the ſame is likewiſe to be aſſerted touching the *Achores* or running ſores in the Head, yielding a thin excrement in Infants. Concerning theſe *Hippocrates* (in his Book of the Epilepſie or Falling ſickneſs, which he calleth *Morbus Sacer*) writeth thus; *Thoſe Infants* (ſaith he) *that have Ulcers breaking forth upon their Heads, and upon their Ears, and upon the reſt of their Body; and ſuch as ſpit often, and abound with Snot, theſe are they that in the progreſs of their age live moſt at eaſe. For hither floweth (and from hence is likewiſe purged forth) that Flegm which ought to have been purged in the Mothers Womb; and theſe Infants that are thus purged are never ſeized upon by the Falling ſickneſs.* Whereas on the contrary, if either the Phyſitians, or the Women-Doctors (as they call them) do without due caution and unſeaſonably adminiſter aſtringent and Repelling Medicaments, and therby heal up the ſaid *Achores*, the Infants muſt then unavoidably fal into Feavers, the Epilepſie, Convulſions (the vitious humor retiring and running unto the internal parts) and ſometimes likewiſe they (within a very ſhort ſpace) even die hereupon.

The Cure.

Now therefore in the firſt place, there is a due care and regard to be had in point of Diet; and there muſt be a totall abſtinence from thoſe Meats that generate aduſt and ſalt humors; *Viz.* all things that are ſalt, ſharp, bitter, Oyls themſelves, and whatſoever partaketh of an oyly Nature: and on the contrary, Meats of a good and wholſom Juyce are conſtantly to be fed upon. And this may alſo be obſerved, and taken for a general rule, that it is more convenient that the food that is given unto Perſons that are thus affected (to wit, with Scabbineſs) be rather boyled than either roſt or fried. For what is either roaſted or fried, doth eſpecially generate a more ſharp and dry humor. After this, the acrimony & ſharpneſs of the humors is to be qualified and tempered; and the diſtemper of the Liver is eſpecially to be reduced unto its priſtine Natural ſtate; and the ſalt and ſharp humors are likewiſe to be evacuated. And therefore (in the very beginning) the firſt waies and paſſages (as we term them) are to be purged and emptied; as for example;

Take *Electuar. Diatholic. half an ounce, Powder of prepared Sene half a dram; and ſo with Sugar make a Bole.*

If there be preſent any extraordinary ſtore of Blood, that the humors are overhot, it wil then be very requiſite and proper to open a Vein in the Arm. For Nature is wont to expel the vitious humors out of thoſe greater internal Veins unto the external branches, and thoſe that lie under the Skin; which from thence (a Vein being opened) are together with the Blood evacuated.

Afterwards (in a moiſt *Scabies* from ſalt Flegm) Preparatives are to be adminiſtred, of Cichory, Agrimony, the Hop, and Maiden-hair; and Purgers of Agarick, Rheubarb, and Sene Leaves. In a dry *Scabies*, Preparers of Fumitory, Borrage, Bugloſs, Violets; and Purgers, of *Epithymum* (we commonly call it Mother of Tyme) Polypody, Sene, black Hellebor: from whence (for this preſent purpoſe) various forms and Receipts may be made and compounded. As,

Take *the Roots of Cichory one ounce, Polypody, ſowr Sorrel, the inward rind of the black Alder Tree, of each half an ounce; of Saſſafras wood, raſped Liquoriſh, of each two drams; Fumitory, Sorrel, Agrimony, Scabious, of each one handful; Epithymum, the Flowers of Borrage and Bugloſs, of each half a handful, Raiſins one ounce and half; boyl them in a ſufficient quantity of common water, or elſe Whey; and for two pound of the ſtreining clariſied, add of the Syrup of Endive and Cichory with Rheubarb, of each half an ounce; of Elder Vinegar, two ounces. Mingle them wel together, and let the Patient take hereof four or five ounces.* Or,

Take *Cichory roots ſix drams; Licboriſh three drams, Fumitory two handfuls, Endive one handful, Flowers of Borrage, Violets, Bugloſs, of each half a handful; the ſeed of Melons, and Endive, of each one dram; the Leaves of Sene one ounce, the Rinds of Mirobolans Citrin. and Ind. of each half an ounce; Polypody of the Oak five drams, the whiteſt Agarick four drams, choice Rheubarb two drams, Spike one ſcruple, Cinnamom, and Ginger, of each half a dram; let them boyl in a ſufficient quantity of Scabious and Fumitory water for two lib.; let them ſtand for one night, and afterward ſtrain and clarifie them; and let them be aromatized and ſpiced with Lign. Aloes, and red Saunders, of each one ſcruple. The Doſe is four or five ounces.* Or,

Take *the Decoction of Sene nine ounces, Syrup of Fumitory, Epithymum, and of Cichory with Rheubarb, of each two ounces; Mingle and aromatize them with Cinnamom, and Spec. Diarrhod. Abbat. half a dram; give hereof at once four or five ounces.* Or,

Take *Fumitory one handful, the four Cordial Flowers of each one pugil, Epithymum half a dram, raſped Liquoriſh two drams, the Leaves of elect and choice Sene three drams, black Hel-*

lebore one scruple, Polypody of the Oak three drams, Raisins stoned two drams, Anise seed one scruple; boyl for four ounces. In the streining infuse of the most choice Rheubarb one scruple, Cinnamom half a scruple, Spike and Schænanth, of each three ounces; unto the streining pressed forth add of the Syrup of Fumitory, and Bizantin. simp. of each three drams; Make herewith a Potion to drink; and let it be taken down as often as need requireth.

If it be requisite, and that the Body stand in need of any further purging, then let the stronger sort of Purgers be administred. As,

Take *Confection of Hamech three drams, Elect. Roses of* Melues *one dram and half, and so make a Bole. Or, dissolve these Electuaries in the simple water, or the Decoction of Fumitory, three ounces thereof; and then add Syrup of Epithymum and Fumitory one ounce, and mingle them: After other preparations and purgations, we may then safely use the infusion of black Hellebore, in this manner prepared.*

Take *the roots of Cichory, and Polypody of the Oak, of each one dram and half; Fumitory half a handful, Flowers of Borrage, Bugloss, and Cichory, of each one pugil; Epithymum and Raisins, of each two drams; boyl them for five ounces: in the streining infuse for the space of one whol night, of the true black Hellebore a dram and half; Cinnamom one scruple, Carrot and Anise seed, of each half a scruple; Cloves five grains; unto the streining pressed forth add Syrup of Fumitory, and of Cichory with Rheubarb of each three drams; Let them be aromatized with one scruple of the Species of Diarrhodon Abbatis.*

But more especially there is here to be administred (as that that is of singular benefit) the Whey of Milk, and chiefly that of Goats Milk; which indeed (in the moist *Scabies*) may first of all be administred, with one ounce of *Succus Rosarum* or the Juyce of Roses, that it may withall purge; and after for four or five daies may only alter. If the *Scabies* be dry, then there may be added two or three ounces of the Juyce of Fumitory, or also two ounces of the Emulsion of the seed of Melons; and thus it is a most efficacious Medicament both against the *Scabies* and the Itch.

Or else the Whey may likewise be prepared after this manner.

Take the Whey of Goats Milk one quart, Mirobalans bruised two ounces, Epithymum one dram and half; infuse them for a night, and in the morning give the Patient one ounce of the streining. Or,

Take the Roots of Cichory, Fumitory, Sorrel, the Sprouts or tendrels of Hops, Agrimony new gathered, of each one handful; Wormword and Rosemary of each one pugil; boyl all these in a sufficient quantity of Goats Milk while it is yet warm, until a fourth part thereof be consumed. Afterward let there be dropt thereinto two or three spoonfuls of Elder Vinegar; and when the Milk is Curdled, the thin and cleer Whey may be taken in the morning, either alone, or (which is better) with the Syrup of Cichory with Rheubarb.

When the Body is sufficiently purged, then it wil not be amiss to administer those things that provoke Sweat. As,

Take Treacle, and Mithridate, of each one scruple, the thickned Juyce of Fumitory half a scruple, Syrup of the Juyce of Sorrel, two drams; dissolve them in Fumitory Water, and so let them be taken in the morning; and the Patient being wel covered in his Bed, let him Sweat for some hours. For this use and purpose, Fumitory alone may be administred, and so may Pimpernel, Columbines, and Elder. But if the *Scabies* be stiff and stubborn, and wil not yield unto the Remedies aforesaid, we may then also use the Decoction of Sarsaparilla; unto which notwithstanding it will not be amiss to add, and therewith to mingle the Water or Syrup of Fumitory.

When these things have been made use of, we are in the next place to betake our selves to Topicks. And here we commend unto you (in the first place) the use of Baths, as wel sweet Baths, as Mineral and hot Baths, among which those that proceed from Sulphur are chiefly commended: the continual use whereof, notwithstanding since that it doth extreamly dry, for this reason it is somtimes requisite and convenient in a dry *Scabies*, by turns to make use of the sweet and Sulphury Baths, so that the Patient make use of the sweet Baths twice, and four times of the other, to wit, the Sulphury. For by the only use of such Baths, and Whey alone, even the most contumacious *Scabies* is oftentimes cured. But seeing that those mineral Baths are not every where to be found, we may therefore substitute and appoint others in stead of them, that have a faculty and power to digest and cleanse, and to open, throughly cleanse, and purge the Pores of the Skin; which if they be mingled together with those things that cool, and mitigate the pain and itching, you have then a most excellent and soveraign Remedy. As,

Take Alum one ounce and half, Sulphur two ounces, Nitre one ounce, Salt a handful; Make hereof a Powder which may be cast into a Kettle full of warm water. Or,

Take Common Salt half a pound, Alum three ounces, Vitriol four ounces, Tartar and Nitre, of each two ounces; let them be throughly bruised, and then cast into the Bath.

In the Bath there may likewise be boyled, Mallows, Fumitory, Scabious, Mugwort, Beets, the Root of four Sorrel; and a Bag hung therein, filled with Bean meal and Bran. There may likewise this following Bath (or such like) be provided. *Viz.* Take

Take Roots and Leaves of the ſowr Sorrel three handfuls: Elecampane Root three ounces: Briony half a pound: Mallows, Scabious, Fumitory, Selandine, Sopewort (which ſome cal Bruiſewort) of each two handfuls: whol Barley, Lupines, Beans, of each half a pound: Bran one pound: Camomile flowers three handfuls: boyl them for a Bath.

For this ſame uſe and purpoſe, Liniments likewiſe and Unguents are prepared; a great number whereof we meet with every where in Authors. They are compounded and made (as I have told you) of ſuch Medicaments as cleanſe and purge the Skin; ſuch as are Nitre, Flowerdeluce, bitter Almonds, Southernwood, Hellebore, the Root of Briony, of white Lillies, Bean meal, the meal of the bitter Verch Orobus, the meal of Lupines, Turpentine, Sulphur, Tartar: Unto theſe you may add and mingle therewith Anodynes, that is to ſay, thoſe Remedies that mitigate the itching, and aſſwage the pain that is excited by other Medicaments; and ſuch are theſe, viz. Oyl of Roſes, Oyl of Dill, and Oyl of Camomile, the Fat of a Hen, Gooſe Fat, the Fat of a Calf, new and freſh Butter, Hogs Lard, &c. Adding likewiſe thoſe things that correct and amend the diſtemper of the Skin; and ſuch are theſe, to wit, the juyce of Sorrel, Milk, the ſeed of Melons: thoſe Medicaments are likewiſe herewith to be mingled that are of thin parts; as Vinegar, and the juyce of Lemmons.

From al which, and other ſuch like (as we ſee occaſion) divers Medicaments are compounded; according to the nature, condition, and conſtitution (together with al other circumſtances) of the body thus affected. For al kinds of *Scabies* or Scabbineſs are not eaſily to be cured with one only Medicament: and whoſoever they be that attempt this, they are juſtly to be accuſed either of negligence or ignorance. For the milder ſort of Medicaments are moſt fit and proper in a mild and moderate *Scabies*, in Children, Women, tender and delicate perſons; and ſo on the contrary: And likewiſe the moiſt *Scabies* requireth one kind of Medicaments, the dry another.

The milder and gentler ſort of Remedies are theſe that follow: Viz.

Take Litharge firſt diſſolved and diluted with Roſe Vinegar, the Roots of white Lillies, of each two drams: Oyl of Roſes two ounces: Bean meal one ounce: Juyce of Lemmons two drams: Camphire four grains: thoſe of them that are to be pulverized, let them be beaten into a very ſmal and fine pouder, and ſo mingled with the reſt into the form of a Liniment. Or,

Take Juyce of ſowr Sorrel, and Elecampane, of each one ounce: Juyce of Lemmons ſix drams; Turpentine an ounce, Litharge half an ounce, Ceruſs two drams, common Salt half a dram, Oyl of Roſes as much as wil ſuffice; and make a Liniment. Or,

Take the Fat of a Hog an ounce and half: Oyl of Roſes one ounce. Turpentine half an ounce: Oyl of Tartar, and the Yelks of Eggs, of each one dram: Pouder of Frankincenſe two drams: common Salt one ſcruple: and mingle them carefully. Or,

Take freſh Butter, and Turpentine, of each four ounces: Oyl of Roſes, and Myrtles, of each one ounce: two Yelks of Eggs: Ceruſs one ounce: Salt two drams: Mingle them wel. Or,

Take the juyce of ſowr Sorrel, and Elecampane, of each an ounce and half: Vinegar half an ounce: Oyl of Roſes and Wax, of each a ſufficient quantity: and make an Unguent. Or,

Take Turpentine waſhed with Roſe water half an ounce: the juyce of ſowr Oranges three drams: the Yelk of one Egg, Butter two drams, Oyl of Roſes as much as wil ſuffice to make a Liniment. Or,

Take Turpentine waſhed in Scabious water one ounce: Oyl of Roſes half an ounce: freſh Butter and Hogs Greaſe, of each two drams: Salt half a dram: Litharge one dram: the Yelks of two Eggs: Juyce of Lemmons ſix drams: Wax as much as wil ſerve the turn to make an Unguent. Or,

Take Juyce of ſowr Sorrel one ounce: Turpentine, and Styrax liquid, of each a dram and half: Elecampane Root two drams: Frankincenſe one dram: the Yelk of one Egg: Salt one dram: Vinegar a dram and half: Hogs Greaſe and Oyl of Roſes, of each half an ounce: Wax a ſufficient quantity to make a ſoft Unguent. Or,

Take Litharge half an ounce: Ceruſs two drams: Maſtick, and Frankincenſe, of each two drams: the juyce preſſed forth of an Orange (the Orange being cut in pieces together with its rind) one ounce: Oyl of Roſes as much as wil ſuffice. Stir them wel about al together in a Leaden Mortar, and ſo make an Unguent.

For the Rich, and ſuch as are tender and delicate, there are wont to be made Unguents of Apples; which they therefore cal *Pomata's* or *Pomada's*; as for inſtance, thus:

Take Cinnamom and Cloves, of each three drams: Lavender flowers two ſcruples, Nutmeg two drams, Styrax Calamite one dram, Benzoin five drams, Camphire one ſcruple, ſweet ſmelling Apples one pound and half, Roſe water the like quantity, Wine four ounces, the fat of a Hog freſh and ſweet one pound: boyl al, and ſtrain them, and then add of Musk half a ſcruple: and make a Liniment.

But in ſuch as are of ful age (eſpecially where the *Scabies* is confirmed and ſetled) the ſtronger ſort of Medicaments are neceſſary. As for Example:

Take the Juyce of ſowr Sorrel one ounce; Sulphur Citrine three drams; Nitre two drams; Liquid Styrax, and Lupine Meal, of each two drams and half; Oyl of Roſes as much as will ſuffice;

ſuffice; a little Wax; and ſo make an Unguent. Or,

Take Sulphur half an ounce; Nitre one dram; Oyl of Roſes, and Oyl of Nuts, of each one ounce; Juyce of Lemmons two drams: mingle them, &c. Or,

Take the Roots of Elecampane, ſowr Sorrel, of each one ounce; boyl them in Vinegar, and let them be paſſed through a fine ſieve. Then add of live Sulphur one dram; common Salt half a dram; of the Juyce of Lemmons ſix drams; of the white Unguent of *Rhaſis*, and of the Citrine Unguent, of each half an ounce; Oyl of Tartar, and Oyl of Roſes, of each as much as wil ſuffice; a little Wax: Make an Unguent. Or,

Take good Wine that is ſweet ſcented, a pint and half; Sulphur three drams; Frankincenſe two drams; Salt one dram and half; Hogs greaſe three ounces; Wax one ounce and half; let them boyl together to the conſumption of the third part; and in the end add of liquid Styrax a dram and half; Mingle them. Or,

Take Root of Pimpernel, ſowr Sorrel, Elecampane, of each half an ounce; let them be infuſed in the Water of Fumitory, and afterward let them be boyled; unto the ſtraining ſtrongly preſſed forth add Turpentine three ounces; Oyl of Roſes two ounces; let them boyl until a third part or the one half be conſumed; and then add of Sulphur half an ounce; Allum two drams; Salgem, and Nitre, of each half a dram; Oyl of Eggs and Wax, of each a ſufficient quantity; and make an Unguent. Or,

Take unſalted Butter four ounces; Turpentine an ounce and half; Sulphur two drams; Salt half a dram; the Yelk of one Egg; and mingle them wel together. Or,

Take Turpentine four ounces, Citrine Sulphur half an ounce; the Root of Pimpernel, Elecampane, *Lapis Calaminaris*, of each half a dram; Salgem three drams; Litharge, and Ceruſs, of each one dram; the Yelks of two Eggs; Allum two drams; a little Vinegar, and Oyl of Roſes as much as wil ſuffice, and make an Unguent.

There are ſome likewiſe that mingle Quick-ſilver and Sublimate with thoſe Unguents and Liniments they make uſe of in this Affect. But in regard that there oftentimes thereby accreweth unto the Patient much dammage and danger; it is therefore the more ſafe and adviſed courſe (in the ſaid *Scabies*) altogether (or as much as poſſibly may be) to abſtain from Quick-ſilver and Sublimate, inaſmuch as the ſaid *Scabies* may be cured by other Medicaments.

And ſometimes likewiſe (for the anointing of the Hands) there are provided little round Balls, Sopes, and thoſe Waſhballs they commonly cal *Smegmata*; as for example:

Take Pouder of the Flowerdeluce Root half an ounce; of Elecampane two drams; Feculæ Brion. and Gerſæ Serpentariæ (by both which you are to underſtand a Pouder made by Art of the freſh Roots of Briony, and Wake-Robin or Cuckowpint, the pouder of which laſt is called Gerſa Serpentaria, and it is as white as Starch or Ceruſs) of each one dram; Choice Frankincenſe two drams; Oyl of Tartar three drams; Liquid Styrax two drams; the meal of Lupines half a dram; the Juyce of ſowr Sorrel three ounces; Venice Sope diſſolved in Roſe water and Fumitory water, as much as wil ſuffice; Musk if you pleaſe half a ſcruple, or ſomwhat more; mingle al theſe, and make a Maſs, and of it little Balls that may be wrapped about with Silk. Or,

Take the diſtilled Water of ſowr Sorrel one pint; the Juyce of Plantane two ounces; Roſe water one ounce and half; Juyce of Lemmons one ounce; Litharge three ounces; Ceruſs two drams; Mercury ſublimate ſix drams; common Salt two drams; Sulphur one dram and half; Pouder what is to be poudered, and then mingle them in the Waters; let them ſtand infuſing twenty four hours, and afterwards deſtill them.

Another experimented Remedy, in al kinds of *Scabies* or Scabbineſs.

Take Roots of ſowr Sorrel (while they are yet green) and of Elecampane, green likewiſe, of each half a pound, Swines fat three ounces; bruiſe the Roots wel in a Mortar, and let them boyl a little over a gentle fire; and after let them be hard preſſed and ſqueezed, and ſo make hereof an Unguent.

Of Malum Mortuum.

Some Phyſitians make mention of a peculiar kind of *Scabies*, which they cal *Malum Mortuum*, becauſe therein the body appeareth black, and as it were mortified; which is a *Scabies* with a wanneſs and blackneſs, and cruſty Puſtules that are black, foul, without any matter, ſenſe, and pain, eſpecially in the Hips and Ankles, taking its Original from Natural Melancholy when it is become aduſt; and thereupon it is that it followeth the uſe of Melancholy Meats, the obſtruction of the Spleen, and the retention of the Hemorrhoids; and without doubt, it wanteth not the ſcorbutical malignity. And it is a Malady (as are likewiſe al Melancholy Affects) of a long continuance, and very hard to be cured.

But yet it is to be cured by preparing the Melancholy Humor, and purging of it in a fit and convenient manner, and by correcting the fault of the Spleen (upon which it dependeth) touching which (as in the Scurvy, ſo likewiſe elſewhere here and there) we have already often ſpoken. The body being evacuated, we are to continue thoſe Medicaments that temper the Melancholy humor; unto which there are to be added thoſe Medicaments that are good and proper againſt the Scurvy.

Further-

Furthermore, let the body be washed with this Bath, prepared and made of the Roots of Polypody, sowr Sorrel, Elecampane, Flowerdeluce, the rinds of the Elder, Danewort, Wormwood, Fumitory, Parietary, and Mallows. When the Patient goeth into the Bath, let there be given him the Conserve of Fumitory, or the Syrup or Water thereof with Treacle.

Afterward let the place affected be anointed with *Unguent Diapompholygos*, or such like.

Take *Juyce of Fumitory, of sowr Sorrel, Selandine, Spoonwort, and Water-Cresses, of each an ounce; the fat of an old Hog three ounces; boyl them until the Juyces be consumed; and then add of live Sulphur half an ounce; Oyl of Nuts an ounce; Unguent Diapompholygos one ounce and half; Frankincense two drams; Turpentine half an ounce; mingle them wel together in a Leaden Mortar, and make an Unguent.*

Chap. 28. *Of* Lepra *of the Greeks.*

LEpra (so called from the Greek word *Lepis*, in Latine *Squamma*, in regard of the resemblance it hath with the scales of fishes) is a certain high, or indeed the highest degree of *Psora* or *Scabies*. But now (at the very first, and before we proceed any further) lest that any one should be troubled, and made to doubt in the reading of Authors, it is to be observed that we here speak of the *Lepra* of the Grecians, and not that of the Arabians. For that Affect which the Arabians cal *Lepra*, is the same with the Greeks Elephantiasis, touching which we shal speak in the next Chapter, which is nothing else than an universal Cancer of the whol body; as it is manifest from the description that is given it by *Avicen* in his *Tertia Quarti*, Tetrab. 3. Chap. 1.) where he saith thus: The *Lepra* is a Disease having its original from black Choler dispersed throughout the whol body; and from whence the temperament of the parts, the form and figure, and at length also the very continuity it self is corrupted; and it is a Cancer common to the whol Body.

But now again the Arabians cal the *Lepra* with the Greeks, *Albaram nigram*, or the black *Albaras*; as appeareth out of the same *Avicen*, in his *Septima Quarti*, Tetrab. 2. Chap. 9. *The black* Albaras (saith he) *is that very same affect that we otherwise also call* Impetigo Excoriativa; *and it is a scabbineß happening unto the Skin, rough, vehement; and it maketh scales like unto fish scales, with an itching, and it is accompanied with a melancholy humor, and it is one of those things that precede and go before the* Lepra: By al which words *Lepra* of the Greeks is manifestly described. For why? *Lepra* of the Greeks is a *Scabies* in the highest degree, and differeth from the *Scabies* only in the vehemency of the Affect. From whence also it is that *Paulus Ægineta* in one and the same Chapter, viz. Chap. 2. of his fourth Book, handleth both the *Lepra* and the *Scabies*: But *Avicen* (whom I had rather follow) treateth of them in several and peculiar Chapters; to wit, of *Scabies*, in the seventh Section of his fourth Book, Tetrab. 3. Chap. 6. But he handleth *Lepra* of the Greeks in the place alleadged.

Albaras nigra, *or the black* Albaras.

For in *Lepra* there is a far greater corruption of the Humors, and consequently a greater distemper than there is in *Scabies*: and in *Scabies* there fal off only certain bran-like substances; whereas in the *Lepra* that that fals off resembleth the scales of Fishes; so that from the itching, by the *Scabies*, there is an easie and ready passage unto the *Lepra*. For this itching is a certain kind of light roughnes in the Skin, in the which (unless haply it be the more violently scratched) there falleth off nothing at al from the Skin. In the *Scabies*, afterward the Humor becometh more evident; and upon the scratching there fal off certain branny bodies. In the *Lepra* the swelling is greater; and there fal off no longer certain smal branny substances, but scaly bodies, whether there be any scratching or not. For in the *Scabies* the matter is more thin, and preyeth upon the highest and utmost Skin alone: but in *Lepra* the matter is more thick, and therefore doth not only feed upon the utmost superficies, but likewise upon the deeper parts of the Skin.

Celsus *his Impetigo.*

And without al doubt, *Celsus* in his fifth Book, and 26. Chap. under the name of *Impetigo* propoundeth and comprehendeth this *Lepra* of the Greeks; and in no wise doth he understand the Greeks *Lichen* (which by others is called *Impetigo*) when he thus writeth: *But now* (saith he) *there are of* Impetigo *four species or kinds; of the which that is least hurtful that in likeneß representeth the* Scabies. *For it looketh red, and is harder, and is also exulcerated, and corrodeth. But it is distinguished from the said* Scabies, *because that it is more exulcerated, and hath Pustules like unto* Vari; *and there seem to be in it (as it were) little bubbles or wheals, out of which in proceß of time smal scales are resolved; and this returneth at some more certain times. A second kind there is worse than the former, almost like unto a* Papula, i. e. *Blister or Wheal, but rougher and redder than it, and having divers forms. There fal off from the utmost Skin smal scales, the corrosion is greater, its progress is swifter and broader; and at more certain and set times it likewise both beginneth and endeth; it is sir-named* Rubrica. *The third sort is yet worse; for it is thicker, and harder, and swelleth more; it is also cleft in the top of the Skin, and it corrodeth more vehemently. It is also in its motion forward scaly, but black; and it creepeth afar*

off

off both slowly and broadly. At certain times it either ariseth or endeth; neither can it be totally taken away, it is firnamed the Black. *The fourth and last sort is that which altogether refuseth to admit of any Cure, and differing in colour: for it is somwhat whitish, and like unto a new made Cicatrice or Scar, and it hath little pale Scales, and some of them are whitish, and some of them like unto a Pimple, which being taken away now and then Blood floweth forth. But otherwise its humor is somwhat white, the Skin is hard and cleft, and it proceedeth broadwaies. Now all these kinds do chiefly arise in the Feet, and Hands, and they also infest the Nails. There is not any one Medicament whatsoever more effectual then what (out of my Author* Protarchus *) I have already related, as appertaining to the* Scabies. *But Serapion hath prescribed of Nitre two pugils, and Sulphur four pugils, to be mingled together, and made up into a Mass with good store of Rosin; and this Remedy he himself likewise made use of.* Thus *Celsus.*

Neither is there any Author either Greek or Latine that hath made or mentioned so many kinds of *Lichenes*: which yet are easily found in the *Lepra* of the Greeks; neither do we meet with any one Chapter in *Celsus*, wherein he treateth of *Lepra*; which notwithstanding although it were unto him unknown, could not possibly be so unto the most studious and knowing *Hippocrates*. Moreover, the *Impetigo* is by *Celsus* said to be worse then even the least and lightest *Scabies*; and furthermore *Celsus* writeth that all the kinds of *Impetigo* do send forth Scales; which indeed is most proper unto *Lepra* of the Greeks; and it is thought likewise to have received its name from *Lepis*, that is, a Scale; whereas on the contrary, never any hitherto hath attributed any scales whatsoever unto *Lichen* of the Greeks. We now proceed to the Causes.

The Causes.

The Cause of this Malady is black Choler. For although there be also some certain of the Ancients that have asserted that *Lepra* likewise ariseth from salt Flegm: yet notwithstandinding this is not so to be understood as if *Lepra* did arise and might be excited from salt Flegm alone, but that salt Flegm is somtimes mingled together with black Choler. And therefore we say, that whatsoever generateth and heapeth up black Choler, the same causeth, or at least very much advanceth the breeding and production of *Lepra*. All which have been already made known out of our former discourse touching the *Scabies*; as for instance, an unfitting Diet, a dry temperament, the Hemorrhoids or monthly Courses suppressed, Issues stopt that had been long kept open and running and a Quartane Feaver. And lastly, Contagion likewise maketh very much to the generating of the *Lepra*, in like manner as it doth in *Scabies*. For albeit there be some that deny that the *Lepra* is contagious; yet notwithstanding they seem thus to do without any evident Cause. For if *Scabies* be contagious, then without doubt *Lepra* is so likewise, it being the worst *Scabies*; and the truth is, it is most agreeable to Reason, that the excess of the *Scabies* should be more contagious then the *Scabies* it self.

Signs Diagnostick.

Lepra is easily known, since that it hath the very same signs with the *Scabies*. This one thing alone is proper and peculiar unto *Lepra*, *viz.* that is sendeth forth Scales. The Sweat is stinking, and the Malady will hardly yield and give way to Remedies. The Skin (as in the *Scabies*) is rough, dry and withered, there is present an itching, and there are certain substances resembling the Scales of Fishes that fall off from them that are affected with it, whether they scratch or forbear scratching.

The Prognostick.

Now this Malady is difficult, very stubborn and contumacious. And unless it be maturely taken in hand, and dealt withall, it wil degenerate into the Leprosie or *Elephantiasis*; to wit, if black Choler be so heaped up together in the Body, that it now seizeth upon not only the exterior parts, but the internal also.

The Cure.

As for the Cure hereof: Seeing that *Lepra* is a *Scabies* in the highest degree, it therefore requireth likewise the same Medicaments that the *Scabies* doth; only they must be made somwhat stronger. Wherefore a good and fitting Diet being ordained, the Body is to be evacuated (as hath been said) the distemper of the Liver to be corrected, and the matter that hath invaded the Skin is by Digestives and cleansing Medicaments to be taken quite away. And in the first place, it will not be amiss here to provoke Sweating with the Decoction of Sarsaparilla, or *Guajacum* Wood. To cleanse, *Galen* (in his sixth Book of the making of simple Medicaments) doth especially commend a Myrepsick Suppository; which in regard that it hath a very strong astringent power, if Vinegar be therewith joyned, having laid aside, and put off its astringent power and virtue, will excellently well discharge the office of Cleansing, and deeply penetrating in all affects of the Skin. Sulphur is here likewise very commodious, by reason of its abstersive Virtue. The rest of the Remedies are specified in the precedent discourse of *Scabies*. And more likewise (which may very fitly be here made use of) shall be said below, in Chap. 4. where we treat of the *Elephantiasis*.

Chap.

Chap. 29. *Of* Vitiligo, *or* Leuce, *and* Alphus.

WHereas in the former Chapter we told you that the *Lepra* of the Greeks is by the *Arabians* called the black *Albaras* (for the *Arabians* mention two kinds of *Albaras*, the one white, the other black) and that the white *Albaras* of the *Arabians* is the same with *Leuce* of the Greeks; and seeing that *Leuce* is a Species of *Vitiligo*; we therefore judg it fit to subjoyn *Vitiligo* unto *Lepra* of the Greeks.

Vitiligo.

The truth is, there be some that strenuously dispute, whether or no *Leuce* and *Alphus*, and the like Evils that we shal anon propound, do belong unto Diseases, or else unto Symptoms; and they scrape together (out of *Galen*) divers places, in which he seems to assert, now this, now that, now one thing, and then another. But since our purpose in this Book is to treat both of the Diseases and likewise of the Symptoms of the extream parts; we wil not therefore scrupulously dispute hereof. Let it suffice that we give you notice of this, that if the recess from the Natural state (whether it be in the distemper, or in the Organical Constitution) be so smal that it hurteth no action, it is then no Disease, but only a symptom; and hitherunto are to be referred the changed colours of the Skin. For although in our former Books we propounded the Diseases and Symptoms of the parts severally and assunder; yet notwithstanding it could not here fitly be done, in regard that somtimes the same Affect (according to the greatness of the recess from the Natural state) is one while a Disease, and another while a Symptom only.

Now unto the word *Vitiligo* (from whence soever it be derived) there is no general Greek word to be found that answereth unto it; but it conteineth under it these three Affects, *Leuce*, and both the *Alphus*, to wit, the white and black. For so *Celsus* writeth, in his fifth Book, Chap. 26. about the end thereof. *There are* (saith he) *three* Species *of* Vitiligo; Alphus *where the white colour is somwhat rough, and not continued; so that there seem to be as it were certain smal drops dispersed. And somtimes it creepeth broader, and with certain intermissions.* Melas *differeth from this colour, in regard that it is black, and like unto a shadow, other things are the same.* Leuce *hath somwhat like unto* Alphus, *but it is more white, and it descendeth deeper, and in it there are white hairs, soft and tender as wool or down feathers. All these creep, but in some faster, in others more slowly.* But *Galen* (as we have already said) hath no common name under which to comprehend *Leuce*, and *Alphus*, but he propoundeth them as divers Affects; in his second Book of the Causes of Symptoms and the second Chapter.

Among the *Arabians* we meet with the word *Albaras*, which they divide into white and black not as one and the same Disease into its Species, but as a word into its significations. For different Affects they are, and *Albaras nigra* or the black *Albaras* is nothing else than *Lepra* of the Greeks, and the *Impetigo* of *Celsus*. But *Alba* or the white, the Greeks term *Leuce*; which appellation *Celsus* doth both keep, and maketh it a Species of *Vitiligo*. Like as *Pliny* also maketh mention of the white *Vitiligo*, in his Book 18. and Chap. 15. and in his Book 31. Chap. 10. But of *Nigra* or the black, in his Book 22. and Chap. 25. For there is no word or name to be found among the Latines that may answer unto the Species of *Vitiligo*, to wit, *Leuce* and *Alphus*.

To wit, Physitians do thus stile *Leuce*, (as *Galen* writeth in his third Book of the Causes of Symptoms, and Chap. 2.) from the Colour imposing the name thereon. For look what kind of flesh Locusts have, and so likewise almost al kind of Oysters, the like hereunto have they also that have their Skins fouled and defiled with *Leuce*. But *Alphoi* are so called from the Greek word signifying to *change*, to wit, because the colour of the Skin is changed; and yet notwithstanding not of the whole Skin, but up and down here and there great spots arise throughout the Skin; and for the most part in the Body also. And the truth is, their generation (as *Galen* there tels us) is of the like kind, to wit, from a vitious nutriment. Yet notwithstanding under these the whol flesh is not vitiated; but only in the very superficies and top of the Skin there are as it were certain little scales fastened thereupon: and the truth is, that *Alphi* or the white arise from a flegmatick, but the black from a melancholly Juyce. And yet they are not true and right scales, but there is a certain kind of roughness perceived in the Skin, together with the change of colour. For in this the black *Alphus* differeth from the *Lepra* or the black *Albaras* of the *Arabians*, that in *Albaras Nigra* or the black *Albaras* there are both excoriation and scales, whereas in the black *Alphus* there are neither.

Morphæa.

Alphus is likewise called *Morphæa*, without all doubt from *Morphe*, to wit, because the colour of the Skin is changed into white and black. *Celsus* hath used the Appellations of the Greeks, in distinguishing the several species of *Vitiligo*; and he hath named the first Species *Leuce*, or *Leuca*: but *Alphus* he calleth only by the single name *Alphus*; and the black he stileth *Melas*.

But now this change of colour (as wel in *Leuca* as in *Alphus*) doth not only consist in the Skin, but is extended likewise unto the Hairs; and as *Celsus* in the place alleadged writeth, in *Leuca* there are white Hairs, such as are like unto the

soft and tender Hair in new born Children; and the white *Alphi* likewise (as *Paulus Ægineta* tels us in his fourth Book, and Chap. 6.) produce white Hairs, and the black *Alphi* black Hairs. And *Johannes Philippus Ingrassias* (in his first Tract of Tumors, Chap. 1. P. 142.) assureth us, that he had more then once seen even old Gray-headed Men that have had some part either of their Beards, or of their Eye-brows black, like as it is in young Persons that are altogether black, to wit, when *Melas* is become inveterate, or that there be present the black *Alphus*; and yet notwithstanding all this while the part affected with the *Leuca* or the inveterate *Alphus*, hath continued white.

From what hath hitherto been said it is apparent and manifest, that by reason of the color there is truly an alliance and neer relation between these two Affects, *Leuca* and *Alphus*; and yet notwithstanding in other respects they much differ the one from the other, since that in *Leuce* there is a change not only in the color of the Skin, but of the flesh likewise, yea also a change in the very substance; whereas in *Alphus* only the Skin, or rather indeed the Scarf-skin, is changed in color.

The Causes.

For touching the generation of *Leuca*, *Galen* in his third Book of the Causes of Symptoms, and Chap. 2. thus writeth: *When the flesh* (saith he) *hath for some long time been nourished with blood both flegmatick, and withal glutinous and clammy, the flesh indeed as yet remaineth, but yet notwithstanding its form is changed, and turned into another species, and it becometh in a certain mean betwixt flesh that hath blood, and that that is altogether bloodless. But when it is become such it then so befalleth it that for the nutriment that is brought unto it from the rest of the body, it doth no more so much as attempt the converting thereof into the red species of flesh, but rather into the likeness of the flesh of Locusts. And so it cometh to pass, that very speedily it is rendered and becometh both white and flegmatick, and that not only in part, but wholly; in regard that it cannot convert the nutriment into a redness, and because that withal that flegmatick humor continually floweth thereunto.* And therefore what kind of flesh (even from the beginning) the Locusts have, (and almost al kind of Oysters) the like (from this transmutation) have they that are defiled and fouled with *Leuca*. For so they cal this vice of the flesh, imposing, to wit, the name from the white color, like as they give the name unto black and callous flesh from the Elephant.

But as touching the generating of the *Alphi*, *Galen* immediately subjoyneth, that the generation of them (together with the vices aforesaid) are of the like kind, but yet so notwithstanding that under them the whol flesh is not vitiated, but only in the superficies of the body there are as it were certain scales fixed and fastened.

But now *Alphus* is twofold; the white that proceedeth from flegm, and by the Arabians is called the white *Morphæa*; and the black that is generated from a melancholy humor, and is called the black *Morphæa*. But yet notwithstanding some there are that constitute other colors also; and they say that the Skin is sometimes changed unto a citrine yellowish color, and sometimes likewise unto a red, according unto the diversity of the corrupt humor. And indeed what they say is not altogether frivolous and to no purpose: for the Skin (true it is) is changed oftentimes, not only unto a white color, or a black color alone; but also very frequently unto a citrine and yellowish color.

The Antecedent causes of these Vices are Humors of the same kind heaped up in the Veins, and by Nature driven forth unto the circumference and superficies of the Body. But now those humors proceed from a default and error in the sanguification; which happeneth either by reason of an ill course of Diet, or else from some sickness and distemper of the Liver. And yet notwithstanding unto the black *Alphus* there concurreth likewise (and that more especially) the vice and distemper of the Spleen. But now with this malady men are more usually surprized and set upon than women. For in women those vitious humors are wont to be evacuated together with the monthly or menstrual purgation. Children are likewise less infested with this malady, in regard that their bodies are hot and moist, and therefore the less apt to breed these kind of Humors; their bodies are likewise open and permeable, and consequently most fit for insensible transpiration.

Signs Diagnostick.

Those Diagnostick Vices are known by the change of the color of the Skin. And indeed the signs of the black *Alphus* are manifest, in regard that there are broad blackish spots (scaly as it were) here and there spread, and dispersed up and down throughout the Skin. But because in *Leuce* and the white *Alphus* there is every where, and on al sides, a white color, these two vices are therefore to be distinguished. In the white *Alphus* the hairs in the place affected retain their natural color; but in *Leuce* there arise white hairs, like unto the soft and tender woolly hairs in yong Children. And likewise in *Leuce* the Skin is more depressed. Moreover in the *Alphi*, if the Skin be pricked with a Needle, there issueth forth blood; but in *Leuce* that which floweth forth is not altogether blood, but a certain waterish and white humor. And lastly, in the *Alphus* the spots are not continued, but disjoyned; but in *Leuce* they are altogether continued,

nued, by reason of the equal vice of the Skin underneath, and the flesh.

Prognosticks.

1. The *Vitiligo* (to tel you the truth) hath in it no danger of death; and yet notwithstanding it is a very filthy and loathsom affect.

2. If it be cherished by any default of the Liver or the Spleen, the Malady is then the harder to be cured.

3. *Leuce* is more difficult to be cured than *Alphus*; and the *Alphus* likewise that hath been of long continuance is more easily cured than *Leuce* that is but newly beginning.

4. That *Leuce* which waxeth not red when it is rubbed, and being pricked doth not bleed, is incurable.

5. That *Leuce* likewise is incurable which seizeth upon, and possesseth a large and spacious room, is of long continuance, and groweth and encreaseth every hour; and also, when all the Aliment that floweth thereunto is corrupted.

6. On the contrary, that *Leuce* that hath yet some kind of redness left in it, and is but smal, is curable.

7. That *Leuce* that is in the hand, or the foot, is of difficult Cure.

8. The white *Alphus* is likewise more easily cured than the black. And in the general, look by how much the color recedes from the Natural color of the body, by so much the more is the Malady the harder to be cured.

The Cure.

This Malady is cured if the Humor that exciteth it be wasted and consumed; and if a course be taken to hinder the further afflux of the like humor unto the skin; and this is done if care be taken that the humor that is already present in the body may be evacuated; and such a course likewise taken, that may prevent the generating of any new humor for the future.

In *Leuce* and the white *Alphus* there is no need at al of Venesection. For the blood doth not here superabound, but that which too much aboundeth, is the thick and cold humors: which are to be prepared by those Medicaments that heat, cut, and cleanse; and such as these are made and provided of Hyssop, Betony, the opening Roots, Stoechas, and others of this kind: and they are afterwards to be evacuated by those Medicaments that purge forth flegm; such as are Agarick, Mechoacan, Turbith, Colocynthis, and the like. *Avicen* maketh use likewise of Vomitories, and Diureticks, that is, those Medicaments that cause and provoke Urine. And then in the close and conclusion we are to administer Treacle, to consume and waste the cold crude humors.

Before Topicks may be applied in *Leuce* the place is first of al to be wel rubbed with course rough cloaths, that so the Medicaments may the better penetrate. Let the Topicks be so ordained and appointed, that they may cleanse, discuss, and draw the blood unto the affected part; such as are those that make red the place, which are very fit and proper in *Alphus*; but those that are stronger, and blisterers, and as it were Caustick, are required in *Leuce*.

Those Medicaments that cleanse, are, Lupines, the seed of the bitter Vetch Orobus, Gentian Root, Beans, Figs, bitter Almonds, the Asphodel or Daffadil Root, Alyssum or Madwort, Nightshade, Sulphur, Pellitory, wild Cucumber Root, and Briony Root.

Those things that attract and draw the blood, rubefie or make red the part, and that likewise excite and raise Blisters, are, Mustard seed, the Herb Rocket seed, Thlaspy or Treacle Mustard seed, Nitre, Euphorbium, Cantharides, the Root of Water Dragon, and other such like, that we have elswhere mentioned and explained.

From these there are divers Compositions to be made and formed. As,

Take *Root of the sowr Sorrel, wild Cucumber, of each one ounce; the greater Celandine, and Fumitory, of each one handful; boyl them in Water, and a third part of Vinegar; and then let the place be washed with the Decoction; and afterward anointed all over with this Unguent,* Viz.

Take *the Juyce of the greater Celandine, sowr Sorrel, Fumitory, and Scabious, of each one ounce and half; Mustard seed one ounce; the fat of a Hen as much as will suffice, and make an Unguent.*

Vesicatories or Blisterers, either of Mustard, or of the Flyes Cantharides, or such like, in *Alphus*, are to be held and kept at least so long in the part affected, until there be sensibly perceived a certain kind of stinging and biting; but in *Leuce*, so long until that the Scarf-skin be parted asunder, and that Blisters be excited and raised.

In the black *Alphus* let the place (the Patient being in a bath) be anointed over with the Pouder of Mustard seed mingled with Water, and made up into the form of a Pultis; and let it be so long there detained until there be felt and perceived a certain mordication or biting: or else let the Pouder of Mustard seed mingled with Sope be somwhat dissolved in Water, and so spread and anointed upon the part. Or,

Take *White Sope one pound; slice it, and let it be so dried that it may be reduced and made into a Pouder. Then add thereto Bean-flour, the meal or flour of Lupines, of each three ounces; Mustard seed one ounce; the Crumb of white Bread one ounce and half; let them be mingled well together with the Juyce of sowr Sorrel.*

But in the first place, it is mainly requisite that the Patient be careful in his Diet, that so the faults

of the blood may be corrected and amended. He must for this purpose feed upon meats that afford a good juyce; and he ought carefully to abstain from al sorts of salt meats, meats that are smoak-dried, and meats that are acid, thick, viscous or clammy. The place affected is dayly every morning to be wel chafed and rubbed, either with a rough course Linen cloth, or else with the hands, being first al over wet with the Oyl of bitter Almonds.

Chap. 30. *Of the Tumors*, Impetigo, *and* Lichen.

WE have already told you above in the 28. Chapter, That *Celsus* his *Impetigo* is nothing else but the *Lepra* of the Greeks. But now the *Impetigo* of *Pliny*, and that we likewise meet with in divers others of the Latins (and of which it is our purpose here in this Chapter to treat) is the same that the Greeks cal *Lichen*.

Mentagra

Unto these *Lichens* there likewise belongeth that that *Pliny* calleth *Mentagra*; touching which he thus writeth in his 26. Book, and Chap. 1. *Even the very face of men* (saith he) *is now sensible of Diseases that are altogether new, and in al former ages unknown, not only in* Italy, *but likewise throughout almost all* Europe. *Neither is it in all parts of* Italy *that these Diseases run up and down, neither throughout* Illyria, *or* France, *or* Spain, *as here at* Rome, *and the parts adjacent, where they most especially prevail and spread themselves; being (the truth is) altogether void of pain, and having in them no danger at all of death; but then they are so foul and filthy, and they so defile the face that any kind of death is to be preferred before this impure Affect. The worst and most grievous sort of these they cal* Lichenes *by their Greek name; but in* Latine *(in regard that the said Affect arose especially from the Chin) they first of all only in a jesting and sporting manner (as too many there are that are Naturally apt and forward to make themselves merry with the miseries of others) but soon after they commonly (and as by a generally received name) cal it* Mentagra, *because of its rise, as I said before, principally from the Chin) seizing upon, and in many places overspreading as it were the whol Countenance, the eyes alone being free, and thence descending both into the Neck, the Breast, and the Hands, together with a filthy kind of bran that it causeth unto the Skin. This Plague (if I may so cal it) was altogether unknown unto our Ancestors, and our Fathers before us were never sensible thereof. And it first of all crept into* Italy *about the middle of the Reign of* Tiberius Claudius Cæsar, *one* Perasinus *a Knight of* Rome, *and being then Quæstor, having been in* Asia, *and thence bringing along with him the contagion thereof. Neither were the Women only sensible of this Malady, or the Bond-slaves, or the mean Plebeians, or the middle rank of Citizens; but even the Nobles themselves catcht it by the swift and secret conveyance of a Kiss; and in many of them (those especially that had submitted themselves unto the Cure that was then practised) the Cicatrice was more foul, deformed, and unsightly than the Disease it self. For they were cured by Caustick; that so the body might not be burnt even to the very bone, where the Malady proved rebellious and refractory. And out of* Egypt, *from whence it first sprang, there came hither unto us such Physitians as undertook the curing of such Diseases; and the pains they took in the Curing of this one only Malady was very advantagious and gainful unto them. For certain it is, that* Manilius Torquatus, *one of the Prætorian Order, when he was sent Embassador into the Province of* Aquitain, *gave two hundred Sexterces for his being cured of this same Disease.* Thus *Pliny*.

There are some indeed that reprehend and blame *Pliny*, and that assert that many yeers likewise before the Reign of *Claudius Cæsar* these *Lichenes* were wel known unto the Grecians; because that *Hippocrates* in the third of his Aphorisms, Aphor. 20. and in his second Book of Womens Diseases, maketh mention of *Lichenes*; and that it is probable that the Malady vexed *Italy* in like manner; forasmuch as *Galen* also in his fifth Book of the Composition of Medicaments according to the places, Chap. 7. maketh mention of these *Lichenes* in the Chin; and yet notwithstanding he hath not one word of their rise and beginning under the aforesaid *Claudius*; and the truth is, that most of those Authors out of which he citeth the Medicinal Remedies against this same Disease, lived before *Claudius Cæsar*. But for this we must here know and take notice, that the *Lichen* is twofold; the one is that which *Hippocrates* & the other Greek Physitians before the time of *Claudius* the Emperor make mention of; and which *Pliny* (with al other the Latines, *Celsus* alone excepted) calleth *Impetigo*; the other that which was before the time of *Claudius*, and altogether unknown, the which others cal *Lichen agria & fera*, or the wild *Lichen*; but most of them have named it *Mentagra*. And this distinction *Pliny* seemeth likewise to have observed, in his Book 20. Chap. 1. and 9. and Book 22. Chap. 25. and Book 23. Chap. 7. and elswhere; and to have called these *Lichenes* of the Ancient Greeks *Impetigo*; but this new kind he calleth only by the single and bare name *Lichenes*, to wit, that so he might not (with the vulgar) make use of the word *Mentagra*, being the name that was at the first jestingly and corruptly imposed upon it. And that this latter sort of *Lichenes* was held to be contagious and Epidemical, *Galen* seemeth sufficiently to hint this unto us, when he writeth, and assureth

assureth us in his fifth Book of the Composition of Medicaments according to the places, Chap. 7. That one *Pamphilus* by the curing of the *Lichenes* got good store of Wealth at *Rome*, when the Disease *Mentagra* (as the vulgar cal it) raged and prevailed here in the City. Both kinds of this Disease *Celsus* in his fifth Book, and Chap. 28. seems to comprehend under the name of *Papulæ*, when he thus writeth: *There are* (saith he) *of* Papulæ *two sorts; the one whereof is, in which the Skin is exasperated by the smallest Pustules, and becometh red, and is gently and lightly corroded; having the middle part of it a little smoother, and creeping along but very slowly: and this same Malady most usually beginneth in a round manner; and for the same reason it proceedeth and creepeth along after the same round manner and fashion. But now the other is that which the Greeks call* Agria, *that is,* Fera, *or wild. In the which indeed the Skin is likewise but far more exasperated and exulcerated, and is more vehemently corroded and gnawed, and thereupon becometh red. And somtimes it also sendeth forth Hairs.* Thus far *Celsus*: All which agreeth very wel with that which *Galen* asserteth in his fifth Book of the composition of Medicaments according to the places, Chap. 7. as likewise *Paulus Ægineta* in his fourth Book, Chap. 3. and *Aetius* writeth in even very same (where he treateth of *Lichenes*) Tetrab. 2. Serm. 4. Chap. 16.

What Lichen *is.*

But now *Lichen* or *Impetigo* (that we may give you the general description thereof) is a roughness of the Skin with dry Pustules, and with an extream itching; creeping forward unto the neer adjacent parts, and in a short space much extending it self.

The Causes.

The Cause is a serous or wheyish, thin, and sharp Juyce, mixed together with a thicker humor. Now this humor is generated either from a bad and corrupt kind of Diet, and salt and sharp meats; or else also from the heat of the ambient Air; which being afterwards thrust forth unto the Superficies of the Body, it there exasperateth the same, and as it were superficially exulcerateth it. And this happeneth more especially in the spring time; whereupon it is, that *Hippocrates* (in the third Book of his Aphorisms, Aphor. 20.) reckoneth up *Lichenes* among the Diseases of the Spring. It likewise now and then happeneth in the Winter time, if by the Air the Pores of the Skin chance to be close shut up, and that sharp and salt humors be therein detained. And yet notwithstanding this Malady may likewise proceed and be contracted from Contagion, or Infection.

The Differences.

Now there is a twofold sort of *Impetigo* (as we told you before out of *Celsus*) the one whereof is more mild and gentle, in the which the Skin is less and by the least sort of Pustules exasperated; and it hath its middle part somwhat more smooth; and it creepeth forward but very slowly. The other that which the Greeks cal *Agria*, the Latines *Fera*, or wild; in the which the Skin is more exasperated and exulcerated.

Signs Diagnostick.

The *Impetigo* is known by this, that the Skin is made hard, dry, rough, and as it were ful of scales: there is likewise present an itching, and the Malady groweth broader from day to day; and from a very smal and inconsiderable beginning it diffuseth it self unto an extraordinary great breadth.

The Prognosticks.

1. This Affect is not in the least dangerous; and that which is newly begun, and mild, is very easily cured.

2. But that *Impetigo* that is called *Agria*, or the wild *Impetigo*, and that which ariseth from a worse kind of humor, is not to be cured but with much more difficulty; and it may soon pass and turn into the *Lepra* or Leprosie.

The Cure.

Such a kind of Diet ought to be ordained, that will not heap and treasure up such like vitious humors, to wit, those that are salt, and sharp.

Moreover if there be any signs, that many of these kind of vitious humors do abound in the body, they are then by convenient Medicaments to be altered, and evacuated.

As for Topicks; the Spittle of one that is fasting (if the part affected be therewith anoynted) healeth and helpeth a mild and Recent or new begun *Impetigo*; and so likewise doth that liquor or moysture that sweateth forth of green Wood while it is burning; as also the Leaves of Wall-Pellitory, or the Root of sour Sorrel bruised with Vinegar: as also the Gum of Prunes, if the part be anoynted therewith; that which is here of singular use and benefit, is, the Oyl of Eggs, and the Oyl of Tartar by draining; especially if mingled together with other fit and proper Remedies. Or,

Take Oyl of Roses one ounce, Tupentine washed in Rose Water, three ounces; Oyl of the Yelks of Eggs six drams, and Oyl of Tartar by draining two drams; and mingle them. Or,

Take Unguent Diapompholyx, one ounce; the White Unguent of Camphire half an ounce, Oyl of Tartar by draining two drams; Mingle &c. Or,

Take Oyl of Wax one ounce, Oyl of Eggs three drams, and of Tartar by draining two drams; Mingle, &c. Or,

Take

Take Frankincense, Ammoniacum, of each half an ounce, Oyl of Yelks of Eggs two ounces, Wax half an ounce; Mingle them, &c. Or,

Take live Sulphur one ounce, Frankincense and Myrrh of each two drams, Camphyre one dram: bruise them into a very smal and fine powder, and add of Borax one scruple, Rose Water a Quart; and destil them. Or,

Take the Flour of Cicers one ounce, Alum half an ounce, Honey as much as wil suffice, make an Unguent. Or,

Take the Raddish root, make it hollow by taking forth as much of the pith as you please; and then fill it up with Salt, Mustard, and Wine, let them stand for the space of one whole night; and then anoynt the *Lichenes* with the Liquor. Or,

Take Chalk beaten to a powder, and let it be mingled with the Juyce of Sengreen in the manner of a Liniment, with which let the place affected be anoynted.

But if the *Impetigo* be fierce, contumacious, and of a long continuance, then there wil be need of such Remedies as do cleanse more forcibly. And here we must commend unto you (as that which is very efficacious) that liquor that is destilled out of the Oyl of Tartar *per de liquium* or by draining, and Quick-silver; as for example,

Take Oyl of Tartar by draining half a pound, Quick-silver two ounces, destil them by a Retort. The Quick-silver wil first come forth; and after it a Water that is excellent against all contumacious and stubborn *Lichenes*. Or,

Take Turpentine washed in Rose Water one ounce, Oyl of Roses half an ounce, Swines Fat three drams, live Sulphur two drams, Nitre a dram and half, Alum, Sugar, Salt, of each one dram, Seed of Stavesacre, Litharge, of each one scruple; Yelks of two Eggs, Wax as much as wil suffice, and make an Unguent. Or,

Take the Flour of Darnel one ounce, Stavesacre seed two drams, the Spume or froth of Silver six drams, Cerus two drams, burnt Lead, and Antimony, of each a dram and half, Swines Fat one ounce, the Juyce of Scabious and of Lemmons, of each six drams; Quick-silver extinguisht or kil'd with Hogs Grease half an ounce, Oyl of the Yelks of Eggs, and Oyl of Tartar by draining, or (as it is usually prescribed) *per de liquium*, of each two ounces; Mingle and make a Liniment. Or,

Take the Leaves of Willows, of Mallows, of the Bur, of the Ivy Leaves, of each one handful; boyl them in red Wine. Let the place be washed with the Decoction; and after the washing, let the leaf of the Bur be laid thereon.

This following Unguent is likewise commended by *Valescus* and *Guido*; *Viz.*

Take the Seed of Juniper shaken wel together, one ounce, boyl them, and to the straining add of Hogs Grease six ounces, Turpentine one ounce; dissolve all over the Fire. When they are removed from the Fire, and cooled, let the watry part be poured off from them, and then let the remainder be diligently stirred about in a Mortar, adding thereto of live Sulphur one ounce, and so make an Unguent.

But if so be that the Malady wil not yield, nor be removed by these Medicaments, but that the part become Callous, we must then make use of Excoriatives, such as *Pamphilus* heretofore used at *Rome*; touching which, and other the like Remedies against the *Impetigo*, we are to consult *Galen*, in his fifth Book of the Composit. of Medicaments according to the places, Chap. 7. and *Aetius*, Tetrab. 2. Serm. 4. Chap. 16.

Chap. 31. *Of* Gutta Rosacea.

A Tumor neerly allied to this *Impetigo* is that which the more modern stile *Gutta Rosacea*, and others *Gutta Rosea*; the *Arabians Albedsamen*, or *Alquasen*, and others likewise *Albutiqaga*, which is a spotted redness, or rather a redness with Tubercles, with which the Cheeks, the Nose, and the Face is defiled and polluted, as if it were all to be sprinkled with Rosie drops. And sometimes these Tubercles get a growth and increase, in so much that the Face becometh unequal, and frightful to look upon, and the Nose augmented unto an extraordinary bigness, and deformity. There lived a yeer or two ago (not far from *Dresda*) a man affected with this Malady, whose Nose grew to such a vast greatness, that it hindred him in his reading; which Malady brought him to that pass, that in the yeer 1629. he was content to have some certain parts and small parcels of his Nose pared away and quite cut off.

Nicholaus Florentinus Serm. 7. Tetrab. 6. Summ. 2. Chap. 15. maketh three Differences of this Malady. *For there is sometimes present* (saith he) *a preternatural redness without any Pustules, Bladders, or Ulcers; and this we call absolutely a red Face; and sometimes this redness is accompanied with Pustules, or Bladders, and then it is called a Pustulous or Bladdery redness; and sometimes it hath attending it an Ulcer; and then we call it an Ulcerous redness.* And this last Difference seemeth very little to differ from that Affect that we call *Noli me tangere*; which they thus describe, to wit, that it ariseth in the Face, and especially above the Chin, neer about the Mouth, and the Nose; and they conceive that it is so called, in regard that (even by those Remedies that seem most fit and congruous) it is rather irritated then any waies mitigated, and notwithstanding all the means that are used, it is more and more carried on by eating and consuming the sound parts. And hereupon it is likewise, that in one and the same Chapter they treat both of *Gutta Rosacea*, and the *Noli me tangere*.

tangere. There is notwithstanding another Affect which they likewise vulgarly cal *Noli me tangere*, touching which we have already spoken above in the 20. Chapter.

The Causes.

The Cause of this Affect is acknowledged to be a hot blood; and the same is likewise thick and gross, and generated through some default in the Liver, that producetb such like blood; the which being carried especially unto the face (as otherwise we see, even in blushing, the blood is easily and soon carried thither, and there diffused) whenas by reason of its thickness it can neither retire back again, nor yet be discussed and scattered, it there sticketh fast in that place; and first of al it causeth a red color of the Face, and soon after likewise (if the said Malady continue long) it generateth red Pustules. Now this distemper happeneth unto some through a default and somthing amis in their Natural Constitution; and these let them live never so soberly and temperately, yet notwithstanding they are nevertheless subject and liable unto this Affect. But however for the most part this evil is contracted and procured by such persons as are addicted to the pot, and given over to drunkenness and swilling; and they are not only those that are excessive drinkers of Wine, but likewise such as exceed in drinking of Beer: and I once knew a Student that was notoriously affected with this Malady, and he had gotten a most foul and deformed Face. This man travelling afterwards into *Italy* and *France* (where there is not that plenty of Beer) at his return home again was much the better, and far less afflicted with the aforesaid Malady than formerly he had been. For Beer is much thicker than Wine, and therfore it also breedeth and supplieth a more thick and gross blood.

The Prognostick.

This Malady is very hardly cured, and especially if the Face be ful of Pustules, and as it were exulcerated; and for the most part it accompanieth the person that hath it so long as he liveth.

The Cure.

Now this Affect is not any other way to be cured, but by taking away the fault of the blood, and what is amis in the Liver. For albeit that the containing cause (as we cal it) of this Malady may be dissipated in the Face; yet notwithstanding it wil not be long ere there be made a new and fresh supply of the same matter. And therefore there must not only be an evacuation of the blood and the cholerick humor (which for the most part is mingled together with the blood) and Cupping-glasses with scarification oftentimes fastened and affixed unto the Shoulder-blades; but especially and in the first place, the extream heat of the blood and liver is to be brought unto a due and fit temper, and the obstructions of the Liver are to be opened; touching which we have sufficiently spoken before, in the third Book of our Practice, Part 6. Sect. 1. Chap. 1. touching the hot distemper of the Liver, and there likewise, Chap. 2. of the obstruction of the Liver. Those Medicaments that are made and provided of Strawberries, Cichory, and whatsoever Compositions that have in them any of the said Cichory, are here most useful and proper.

As for Topical Remedies, let them be cooling, when the Face is only red, and not yet defiled with Pustules; but if with the redness there be also Pustules accompanying it, then the Medicaments ought likewise to be such as have in them a power and vertue to discuss.

Now these Remedies are administred in the form of Waters and Liquors, as also of Liniments and Unguents. As first thus:

Take the Root of Solomons Seal three ounces; Flowers of Elder, of the Valley Lilly, of the bitter Mushroms, of each six ounces; white Tartar an ounce and half; white Wine a pottle; Camphire two drams. Let them stand infusing in the Wine ten daies, and afterward destil them.

Take Wheaten Meal as much as you think fit, Goats Milk one quart; make hereof Dough, and making it into Loaves bake them in the Oven; and let this Bread be again macerated in Goats Milk for the space of twelve hours. After this add the Whites of twenty Eggs, Camphyre one ounce; burnt Allum two ounces; Destil them, and make a Water. Or,

Take Strawberries a pint, Goats Milk a quart, the Whites of twenty Eggs, the Seed of Quinces two ounces, Camphyre two drams, Allum and Sulphur, of each half an ounce; mingle and destil them.

Lac Virginis (as they cal it) is likewise very good for this purpose, made of one part of Litharge, and three of Vinegar. But this following is more efficacious:

Take Litharge half an ounce; Vinegar four ounces; let them boyl to the consumption of the third part; and in another Pot boyl of Salt and Allum, of each half a dram; Frankincense one scruple; Rose water half a pint: Mingle both these Liquors, and pass them through a Linen strainer; and keep it for your use. Or,

Take Sulphur two drams; common Salt, and Camphyre, of each half a dram; Cerus, and Litharge of Silver, of each two drams; make them into a Pouder, and then mingle them carefully with the Water of Bean flowers, Rose water, white Lilly Water, the Water of Solomons Seal, of each two ounces: Mingle them, &c. Or,

Take Camphyre one dram; pour unto it into the Mortar by a little at once, and stirring it wel about,

about, of the Oyl of sweet Almonds three drams; afterward pour thereunto of the Oyl of Tartar by drawing two drams; and then moreover add of the Yelks of two Eggs, and mingle them wel together. After this add of *Saccharum Saturni* or Sugar of Saturn, half a dram; mingle them with al possible care, and then at the length pour in unto al the aforelaid (by a little at once) the Water of Bean flowers, of white Lillies, and of Strawberries, of each two ounces; and so mingle them al wel together. Or,

Take Litharge one ounce; Allum three drams; Ceruss half an ounce; Vinegar two ounces; the Water of Roses, and Plantane, of each four ounces; boyl them until a third part be wasted away, then strain them; and to the straining add a little of the Juyce of Lemmons; and with this mixture let the Face be anointed in the Evening. Or,

Take the Kernels of Peaches clean peeled, bitter Almonds blanched, of each in number six; beat them wel in a Mortar with a little milk; and then let their milky Juyce be presséd forth; unto which add of burnt Allum as much as a Nut. Afterward take of Quick-silver as much as a great Pease in quantity; which together with Spittle shake wel, and stir it about in the Mortar until it become black, and be as it were mortified; and then mingle it carefully with the former Liquor, with which about bed-time let the Face be anointed; and then in the morning following let it be washed with Rose water, or the Water of Bean flour. Or,

Take the whitest Tartar, Allum, and Nitre, of each four parts; Sulphur one part; bruise them wel, and then Calcine them; and in a Cellar from them make an Oyl *per deliquium* (as they speak) or by drawing. Or,

Take Kernels of Peaches hulled four ounces; the seed of Gourds peeled two ounces; let them be bruised, and then the Oyl pressed out of them; with which let the Face be wel anointed both morning and evening, and afterward washed with Rose water, and Bean flour Water, and the Water of Solomons Seal. Or,

Take Camphyre, Litharge, burnt Allum, of each half a dram; live Sulphur a dram and half; White Vitriol, and Frankincense, of each one dram; let them be poudered, and carefully mingled with Rose water, and Bean flour Water. Or,

Take Live Sulphur one ounce; Choice Frankincense three drams; Myrrh two drams; Camphire one dram; Ceruss half a dram; Pouder them al very smal, and pour thereto of Rose water one pint, mingle them; and when the Patient goes into his Bed let his Face be anointed with the said Liquor; and the morning following let it be washed with the water of the infusion of Bran. Or,

Take Oyl of Tartar one dram; Sulphur two drams; Camphire half a dram; Ceruss and Litharge, of each half an ounce; Rose water as much as wil suffice; and so let them stand in the Sun in a Glass close stopped. Or,

Take one whol Egg, and put it into the strongest Vinegar for four daies, until the shel be softened; afterward take forth the white, and fill it up with Frankincense, Mastick, and Ceruss, of each one dram; mingle them, &c.

Chap. 32. *Of Crusta Lactea, Achores, Favi, Tinea, Ficus, Helcydrium, Psydracia, and Phthiriasis.*

OUt of the Humors mingled together there are likewise generated both Tumors and Ulcers in Infants, that seize especially upon their Heads; touching which we have already treated in the fourth Book of our Practice, Part 2. Chap. 3, 4, 5. where we handled the Diseases of Infants, and therefore I conceive it altogether needless here to repeat any thing of what was there at large delivered. I shal only therefore here further acquaint you with these few things following. The first whereof is this, That these Affects here propounded, as likewise those which we have next of al explained, are indeed by the most referred unto Tumors: and yet notwithstanding (because there is here an Ulcer evermore conjoyned with these Affects, and the truth being that the Ulcer seemeth rather to have in it the Nature of a Disease, than the Tumor hath, which is indeed but very smal and inconsiderable) we judg that they may alike fitly and properly be referred unto Ulcers. But yet however our purpose is to continue the same Method (and as I may so say, to spin the same thrid) that we find begun by most Authors, and according to their guidance and direction. And moreover, as for what concerneth the Affects here propounded, what we are to understand by *Crusta Lactea*, and what we mean by *Achores*, *Favi*, and *Tinea*, we have already told you in the place before alleadged: as for *Helcydria*, *Psydracia*, and other the like Affects of the Head (comprehended under the general name *Exanthemata*) they are al together handled by *Galen* in his first Book of the Composition of Medicaments, according to the places affected, and the last Chap. but by the rest of the Greeks in divers and distinct Chapters. *Halyabbas* seems to comprehend them al under the name of *Tinea*, whenas in the eighth Book of his Theory, and Chap. 18. he thus writeth: *But these Ulcers* Tineæ (saith he) *are very smal, and they happen unto the Head; and there is in them a bladder that hath many species and kinds. The first whereof is that we cal* Favosa, *which hath its original from a salt flegm: the sign whereof is this, That there is an Ulcer whereby the Skin of the Head is perforated, and ful of little holes,*

in

THE THIRD DISCOURSE.

Of Atomes and Mixture.

Chap. 1. *Of Atomes.*

NOT only Words (like Money) are current by uſe, but alſo Opinions; and thoſe Opinions of Philoſophers which were in requeſt in daies of old, have been by the ſpringing up of other Opinions baniſhted with the Writings of the ſaid Philoſophers. There were anciently (by the Teſtimony of al Antiquity) moſt wiſe men, *Pythagoras*, *Empedocles*, *Democritus*, *Socrates*, *Anaxagoras*, *Parmenides*, and very many more, whoſe Opinions nevertheleſs are either altogether unknown, or ſuch are attributed to them as ſeem more like old Wives Fables, than Opinions becoming a wiſe man, as *Fr. Titelmannus* ſpeaks, *Lib.* 5. *Philoſ. nat. cap.* 15. which if they were by us rightly underſtood, peradventure we ſhould think them not altogether to be rejected; which nevertheleſs now at the firſt appearance, when they are not underſtood, are laughed at as abſurdities, and rejected as unworthy of Philoſophers. Truly *Ariſtotle* in his Works, every where recounts the Opinions of the Ancients, and ſharply oppoſes the ſame; but *Pererius* ingenuouſly confeſſes in *Lib. Comment. de rer. natur. princip. cap.* 16. That he cannot deny but that *Ariſtotle* in making Inquiſition into, and judgment upon the Opinions of the Ancients, was too hard and ſevere a Judg and Arbitrator. And in the ſame place he relates the Opinion of *Simplicius*, who conceived that thoſe ancient Philoſophers were accuſtomed to hide their Opinions under ænigmatical and allegorical obſcurities: and therefore *Plato* and *Ariſtotle*, fearing leſt rude perſons as were too dul-headed to underſtand their abſtruſe ſence, underſtanding them according to the firſt appearance ſhould fal into Error, did ſo handle their Opinions as that they might ſeem to common Readers to diſlike and reprove the ſame. Not to ſpeak of others, *Democritus* who lived when *Hippocrates* lived, as appears not only by the Epiſtles of *Hippocrates*, but alſo out of *Diogenes Laertius*, and *Pliny*, *Lib.* 30. *cap.* 1. was a man moſt ſtudious of Philoſophy, and diligently weighed the Opinions, not only of *Anaxagoras* (whoſe junior he was by forty yeers, as is reported) but alſo of the Outlandiſh Philoſophers, and many years together (to attain Wiſdom) he travelled ſtrange Countries, *Chaldæa*, *India*, *Perſia*, *Æthiopia*, *Egypt*, and heard and conſulted with the great and wiſe men of thoſe places, as it is to be ſeen in *Ælian*, *de varia Hiſtoria*, *Lib.* 4. *cap.* 20 Diogenes Laertius *in his Life*, Clemens Alexandrinus, *Lib.* 1. *ſtromat.* and Euſebius, *de præparat. Evangel. Lib.* 10. *cap.* 2. Pliny, *Lib.* 30. *cap.* 1. And during the long time of his Life (for he died in the hundred and ninth year of his age) he diligently examined al things, and did ſo excel in Philoſophy that he was called commonly *Pentathlos*, the Champion at five Games, viz, Becauſe he was eminent in Natural, Moral, Mathematical, and other Diſciplines; termed by *Hippocrates* in his Epiſtle to *Damagetus*, the *Wiſeſt of Men, the moſt Wiſe Man*, and in his Epiſtle to *Democritus*, *The moſt excellent Interpreter of Nature and the World*; and by *Ariſtotle* himſelf in 1. *de generat. & corrupt. cap.* 2. *text.* 5. he *is* preferred before al other ancient Philoſophers in the Science of Nature. And by the Senate and People of *Abdera* he was ſo highly eſteemed, that they

The praiſe of Democritus.

they write in their Epistle to *Hippocrates*, That they feared it *Democritus* should be sick the City of *Abdera* would become quite desolate; and in the same Epistle he is termed the *Body of Wisdom*. Yea, they called him *Philosophy* it self, as *Ælian* relates in the place fore-alleadged. And this alone argues his great care in the study of Nature, that *Pliny* writes *Lib.* 14. *cap.* 2. Whereas there are innumerable and almost infinite sorts of Vines, and almost as many as there are Fields, yet *Democritus* was the only man that conceived their kinds might be numbred, professing he knew al that grew in *Greece*. It is not therefore credible that so sagacious a Philosopher, a most wise man (as *Hippocrates* called him) one so useful to Humane Life (as *Pliny* calls him, *Lib.* 28. *cap.* 8.) should entertain such absurd Opinions as are at this day fathered upon him; nor is it (indeed) likely (to use the words of *Pererius*, *Lib.* 4 *Phys. cap.* 4.) that so discreet and wise a man, so many wayes commended by *Aristotle*, should beleeve and reach things so evidently false and absurd, not only secretly contrary to Reason, but likewise openly against the very Verdict or the Senses.

The Doctrine of Atomes a most ancient Doctrine.

Now amongst other Opinions ascribed to *Democritus*, *Empedocles*, and other most noble ancient Philosophers, is this; That they held Atomes or individual Bodikies to be the Principles of Natural things, from the various mixture whereof other Bodies have their Original. And this Opinion was a most ancient Opinion, and is now attributed to one *Mochus* a *Phœnician*, who is reputed to have flourished before the destruction of *Troy*; yea, and that it was the common Opinion of Philosophers before *Aristotle*, is apparent from the beginning of his Second Book *de Generat. & Corrupt.* *Aristotle* was the first that relinquished this Opinion, and held that those Atomes or smallest Bodikies were not only united in mixture, but also by mutual action and passion one upon another so altered and wrought upon, that they ceased to be what they were before their mixture, and were changed into a Body so similar, that every smallest part imaginable could be no longer called Fire, Water, Air, or Earth, but a mixt Body. Of which we shal speak more largely when we come to speak of Mixture. And although the Doctrine of Atomes and Indivisible Bodikies be commonly set out after an odious manner; yet if rightly explained it seems not absurd. Yea, the Reasons brought for this Opinion are not light or foolish, but strong and urging, and which can hardly be answered, as *Aristotle* himself confesses, *Lib.* 1. *de Generat. & Corrupt. cap.* 2. *text.* 6. and which he cannot certainly promise to answer, but he would try what he could do. And doubtless he knew he could not sollidly refute this Opinion, and therefore he used not proper and Physical Reasons as he ought to have done, but Mathematical and extravagant ones.

'Tis founded on Reason.

The Doctrine of Atomes explained.

Now I conceive the Doctrine of Atomes may be thus explained. In Natural things subject to Generation and Corruption, because there is a perpetual Interchange of Generating and corrupting, there must needs be certain simple bodies, each of a nature by it self, out of which the Compounds may be generated, and into which Compounds are again resolved. For *Democritus* seeing that Bodies Natural were neither made of nothing, nor made of Points, he was forced to hold they were made of the smallest Bodikies. Where it is to be noted, That *Democritus* did not enquire, Whether there were an individual Mathematical Magnitude; but whether there were Natural Bodikies of an indivisible smalness, out of a multitude of which gathered together a certain sort of natural Body does arise. These Bodikies are therefore termed the smallest particles in Nature, Atomes, *Atoma corpuscula*, indivisible Bodikies; because in the resolution of Natural Bodies there is no further progress to be made beyond these into any thing smaller; and contrariwise Natural Bodies have their original from these. Which Bodikies are indeed really in Nature, but are so smal as they cannot be discerned by the Senses. Of them *Plato* in his *Timæus* thus writes: Touching these so smal Bodikies we are thus to think, That if you take only one single one of a kind, there is none of them can be seen by us in regard of its smalness; but if many are collected together, their bulk and magnitude is discernable. For neither are those little Bodikies we see floating up and down in the Sun-beams such Atomes as we speak of, but compounded Bodies. Al the Learnedest Philosophers have acknowledged that there are such Atomes, not to speak of *Empedocles*, *Democritus*, *Epicurus*, whose Doctrine is suspected, perhaps because it is not understood. And *Galen* makes mention of them 1. *de Elemens. cap.* 9. And indeed every where amongst Philosophers and Physitians both Ancient and Modern, mention is made of these little Bodikies or Atomes, that I wonder the Doctrine of Atomes should be traduced as a Novelty. That I may not speak of others besides those whom I have already praised, who may be suspected as Contemners of the Ancient Philosophy, and desirous of Novelties; *Franciscus Aquilonius*, *Lib.* 5. *Opticæ defin.* 5. thus writes: Amongst

the manner of Atomes.

Many have held there are Atomes.

Elementary

Elementary Qualities, the two which are termed passive are exceeding far from the Nature of Light. For neither does Humidity signifie a Quality, nor Humectation an alteration. For humidity in the substance of Water is the same thing that fattiness is in the substance of Oyl; and as fat makes Greasie by being smeared upon a thing, so moisture moistens only by sticking to a thing. Again driness is only the defect of moisture, and exsiccation the consumption of Humor. And among the active Qualities Cold sends forth no coldness out of it self: which though it may to some seem strange, yet is it agreeable to reason, and experience manifestly demonstrates the same. For the coldest body that is (to feel to) as Ice, does send forth no sense of coldness to ones hand that is neer it; but al cold things are perceived to be so only by handling them. Which (to such as denied the same) I have often made appear by a pleasant experiment: for their eyes being blinded and their hand held forth, I would ask them if they felt the coldness of the Ice neer their hand. For sometimes they would say they felt somwhat when there was nothing near them; and otherwhiles they would say they felt nothing when the Ice was so neer their hand as it did almost touch the same. And a while after he saies; Heat seems to diffuse it self abroad like Light. Moreover, I account it (truly) most likely that from the kindled fewel a kindled vapor does flie abroad, which being secretly conveighed through the Air does heat every thing it touches, and also burns the same if it have any thickness. Hence it comes to pass that things set near a blazing fire are burned though they do not touch the visible fire it self, which is often seen in Paper and Tow; but much more apparently in Naphtha, Asphaltum, Amber, and such like, which draw the flame to them from afar. Hence also it comes to pass that the fire heats more strongly and fiercely aloft than beneath or on the sides, viz. Because the inflamed vapor attenuated by Heat endeavors to mount upwards. Which truly does not properly agree to a quality, but to a substance. Nor can you rightly say Heat is Light, but that which is hot. For that being by the force of heat rarefied becomes lighter; as that is heavier which by condensation of the matter is brought into a narrower compass. Hence also the true cause may be rendred, why in the Winter flames do blaze more lustily: for the surrounding cold hinders the heat from spreading it self abroad in the Air. And in the same Book, *Propos*it. 2. We must cal to mind what was said, *definit.* 5. of this Book, how that the Heat of the Fire is not carried along by a continual action, but is secretly conveighed through the Air, just as smels which breath out of odoriferous Bodies, and being received in the thin Air, and founded in a secret exhalation, are carried this way and that way by *bab nab.* So (I say) the fiery heat being carried in a certain kindled Spirit is thrust strait along, as much as the power of the fire is able; very speedily upwards, but the more slowly by how much the more downwards. But being set at liberty it wanders more freely through the Air, and is driven any way by the lightest motion, and by its sticking to them things never grow warm, as those which are placed by odoriferous bodies do smel sweet only by exhalations sticking to them. Soldiers in their Camps find this by experience, when having cut down a great deal of Wood they pile it up and set it on fire in the middle of a field, and stand round about the same. For they that have the wind on their backs do feel hardly any heat although they stand close by the fire, the fiery spirits being thereby carried unto the opposite side; which the wind could not do if only a quality were carried through the Air; for that being no body would give the wind a free passage through the Air. Thus far *Aquilonius.*

'tis proved that there are Atomes.

But what need we Authorities when the matter is plain enough of it self? For if we consult with Experience, which *Aristotle* so commended in *Democritus*, we shal find both the Generations and Corruptions of things to be made by Atomes, and that there are every where in Nature examples of the uniting and separating of Atomes. And since there is not only one kind of Atomes, but that they are various according to the variety of Bodies, I conceive it wil be best to consider them both in respect to the Elements so called, and in respect to bodies compound.

For in the first place, The Elements themselves are resolved into such Bodies, and the said Bodies joyning again do make up not only Compounds, but also the bulk it self of the Elements. Now these Atomes or indivisible Bodikies of the Elements do arise both out of the resolution and corruption of Compounds, and likewise out of the Terrene Globe (wherein are al Elements) and are carried up into the Air; whence proceed sundry mutations of the Air, and Generations and Corruptions, which variously affect both Man and Beasts, and Plants. For it is very true of the first Atomes or indivisible Bodikies, that if we take but one Atome of a kind there are none of them visible: but if many of them be gathered together their magnitude and bulk is discernable, which (as hath been said) *Plato* also teaches us in his *Timæus.* Since therefore these Bodies are most smal and subtile,

they do both easily pierce into other Bodies, and afford matter also to others.

Fiery Atomes or Bodikies. To run through al kinds of Natural Bodies, and first as to Elements; Fire insinuates it self into Iron and Water. The same being insensibly in the Summer mixt with the Air makes soultry hot weather; yea, and (as Experience shews) hath burnt up Woods sometimes. It is variously mingled also with other things, and according to its various commixture makes sundry sorts of things. Fire indeed of it self (as *Jul. Cæs. Scal.* teaches) neither shines nor burns; but that it shines and burns it comes to pass by the admixture of another Body, and the propinquity of the parts, by whose co-action in a smaller space the substance is greater, and therefore the force is greater. But being rarefied it burns not, nor does it shine. That smoak which ascends hath much fire in it. Nor yet hath it any burning Faculty, nor shines it at al with any light: and such things as are roasted on Spits are not touched by that fire which we see; yet are they so touched by fire, as that they are somtimes burnt to a Coal. Yet is not that fire visible which burns them. And the same *Scaliger, Exercit.* 325. *Sect.* 7. Fire is much more transparent than the Air, because it is thinner. The Fire which we use is yellow because of mixture. For there is fire in a vapor, in smoak, in burning coals, in a flame; and *Aristotle* cals a flame burning smoak, and that not amiss. For the flame seems to be no other thing than the meeting together and union of the particles of fire, the heterogeneal substances being separated. For whereas by reason of distance and commixture of Contraries the smal bodies of fire could not joyn together, the obstacle being taken away they begin to be united. Hence it happens that if the chamber where fire is kept be close shut the fire wil not flame, but as soon as the Air is let in, and those heterogeneal bodies are discussed, the flame breaks forth. Nor yet is flame absolutely pure, but contains in it self some heterogeneal Matter, which the color alone does shew. But that fire which is above the flame is purer; and therefore is not seen. For by reason of the different concourse of the Atomes divers bodies seem to arise which yet are of one Nature. The Fire is but one thing, yet undergoes divers names, according to the different concourse of its smal bodikies. The Concourse of many homogeneal bodikies of fire is requisite to make fire in such a condition as to shine and burn; which two things though fire does not, yet is it fire stil.

Aerial Atomes. Now Air is in al bodies almost. For since most Natural Bodies are porous, Air fils those empty spaces naturally. Not to speak of other things, some Metals are sounding, others not. And those which sound have Air in their pores, which is the subject of sound. So Woods are apt to admit sound, which happens only by means of the Air contained in them. And this is most frequent in dried Woods; because the watry moisture being consumed, which was unfit to receive sounds, Air comes into its place by its quality more fit to receive and advance sounds. And if a man touch a stick at one end, and put the other end to his ear, he shal hear a sound. Which comes to pass by means of the Air which is contained in them, seem they never so solid. And Soldiers are wont to try whether their Enemies are coming by clapping their Ears close to the Earth.

Watry Atomes or Bodikies. Water or moist Air (which is nothing but Air ful of the vapors of water) does so insinuate it self into wooden things that they wil even be thereby swollen in bulk. And therefore folding doors many times when the Air is moist, wil neither open nor shut. And tubs that leak being laid in water come to hold again, because the boards which were contracted and made chinks, are by the water distended.

Earthy Atomes or Bodikies. Finally, The Earth though it be thick, yet it insinuates it self by its smal bodikies into other things, and is mixed with them. So we see in Baths, Icesickles, and stoney substances grow to the Channels, so that a man might wel wonder how such a body could lie so long concealed in clear and transparent Water. If therefore Air and Water can so insinuate themselves into solid Bodies, and Earth can be so mingled in transparent Water as not to be discerned by the sight, why therefore may not fire do the same which is much more subtile? So that there is now no need to dispute how red hot Iron burns, since really it contains in it the Atomes or smal bodies of fire, which vanishing away it returns to its Natural actual coldness. For the same cause also Metals are melted, and afterwards growing cold become hard again. Of which we shal speak anon.

Alteration what it is. What heating is. Which if a man diligently consider, he shal observe, That alterations commonly so called are not mutations only in Qualities, but the participation of another Body: that the heating of water is its participation of fiery Atomes, by means of which also it hath the power to burn, which vanishing the water returns to its ancient coldness. Which also may be known even by Experience; for hot water shut up in Peuter Pots wil retain its heat ten hours and longer in the Winter time; by which means Beds are warmed in the Winter, and Gentlewomen

women travelling by Coach defend their feet from the Winters cold. For if the water had contracted only heat from the fire, that imprinted quality in a cold place, in a Vessel made of Metal, and in the cold air, could not continue so long a time. There are therefore (doubtless) fiery particles, which being shut up in a thick Metalline Vessel do for some time abide therein, before they can al leisurely creep out through the pores of a compact Body. So in the Summer time we are taught by this following Experiment, That Wine and Beer do not only contract an hot quality in the heated Air, but that they also receive into themselves fiery particles, viz. If two Vessels be filled at the same time with Wine or Beer, and both be plunged a good way into cold water, and then one be stopped, the other open, that Wine or Beer in the open mouthed Vessel is sooner cooled than that in the stopt vessel; which therefore happens because the fiery Atomes which did heat the Liquor being compelled by the force of contrary coldness do sooner exhale when they have a free passage than when by stopping the vessels mouth they are restrained. Yea, and it is not absurd to say the Air in our stoves is not only altered, but receives into it some of the substance of the fire. Nor is it impossible that the fire should pierce through the furnace, since air (not so subtile as fire) pierces both into Iron and stone Jugs. Yea, and the thing it self testifies thus much; for we see paper, cloaths, and other combustible things being held near the hot stove do oftentimes take flame. And if those supposed alterations are meerly such, how can heat and cold be in the same part of the water; and seeing no accident operates but by vertue of its form whence it flows, how can that heat springing from the fire act both upon the cold and upon other Bodies, the fire whence it came being now absent and quenched. Now whether is more absurd to hold that in water there is also fire, from whence as its proper subject heat flows? or to hold heat to be both in its own proper, and in a strange subject? And that this is true many most learned men have acknowledged, and amongst the rest *Averrhoes*, who in his B. *de Anima, text.* 115. writes: We must not think that water is heated remaining pure and meer water, nor that Air is cooled remaining meer and pure Air; but this happens by reason of hot or cold bodies being mixed with them. Also this is manifest in the cold air, which nips Plants less being stirred with winds than if it be stil and quiet. For the cold Atomes mixt with the air and sticking to the Plants do more hurt than when they are stirred. *Julius Cæsar Scaliger* grants as much, when in *Exercit.* 12. *Sect.* 3. he saies that Brass becomes hot by the parts of the fire entring into the pores thereof. The same *Scaliger*, *Exercitat.* 14. teaches us, That boyling water is fiery, or hath in it fire and dryness; and he writes that the fire exhales out of hot water: *There is* (saies he) *fire and dryness in hot Water, which in the steam ascending we perceive by our understanding, and by our sense also; for it burns. The heat which is in water is fire mingled with its contrary.* Yea, and *Galen* taught this long ago, who in his 1. Book *de Element. cap.* 6. saies, *I say that he who in the time of frost is warmed with the fire, does receive fire into his Body.* And that the substance of fire and air does penetrate into other bodies, this also argues that the digestions which are performed in dung or hot water can never be exactly accomplished in the Embers, whatever degree of heat you shal use; and because in an hot and dry subject a thing is easily burned, but not in an hot and moist. Also the Cure of burns, and of parts nummed with cold, as also other things congealed with cold do shew, that alterations hitherto so esteemed are not meer alterations, but the mixture of a certain kind of Atomes. For if a man shal put frozen Eggs or Apples into hot water (which should be done were it a meer alteration) they wil be spoiled: but if he plunge them in extream cold Water, the frost is drawn, and sticks like Ice upon the out side, and they are preserved. So those that travel in the Winter, as is wel known to the Inhabitants of *Norway* and other Northern Countries (nor is it altogether unknown to our people) and have their Members frozen as it were; if they come presently to the fire or into an hot room, they are very much hurt and exceedingly pained, and many times the part becomes gangrenated, the cold parts (I do not say the coldness, but the cold parts or atomes) piercing inward, and extinguishing the natural heat. But if their Members are first rubbed with Snow, or are plunged into cold water, the water or Snow do draw unto themselves by reason of similitude those atomes and petty cold bodies which had gotten into the part. Contrariwise, when any Member is any waies burnt, if it be plunged into cold water (which the Law of alteration requires) it is most certainly endangered. Contrarily 'twil be cured if it be put, not into cold but hot water, which may by similitude draw to it self those hot bodikies: and if the burning be not great, the Member may be held to the fire, or hot embers may be applied thereto. Of which *Fernelius*, 6. *de Method. Medendi, cap.* 20. As the fire, if a part which is burned be held neer the same, becomes a cure of the evil it self caused, and by drawing back the fire eases it of its pain; so

some

some things externally applied do by their heat draw out the heat of the fire, and so by ceasing the Inflammation they cure burnings. For fire and hot things do by similitude draw out the fiery Atomes. And for this very cause (as *Aristotle* writes in the 13. Probleme of the 24. Section) hot things are faster cooled in the Sun than in the shade, because the beams of the Sun draw out the fiery Atomes.

The Fire is no Accident.

But that same Opinion of *Thomas Fienus* is altogether absurd, who in his Apology against *Sanctacruz*, Page 50. saies, that this Fire of ours which we use (he cals it artificial and earthly, unfitly; since it is most natural and of the same substance with that Fire which is in other parts of the world, although it be in a thicker matter) is an Accident; and he conceives that those things which are said to be Fired, or those substances which men are wont to call Fire, as Iron, Coals, Flame, are indeed Substances: but that which is in them more than their own substance, by reason of which they are called Fire, or are said to burn, he denies to be a substance, and thinks that the fierineſs adds nothing to the burniug Iron, Wood, or Furnace, but an Accident, viz. a most intense Heat, and that he endeavors thus to prove.

First, He saies, a substance is not capable of more or less. That same firineſs in the Iron, Wood, Furnace, admits of more and less. *Ergo* it is no substance.

Secondly, When the Iron is red hot or the smoak flames, the whol Iron is fired, and the fire is in all the parts thereof. If therefore the fire were a substance, in all the parts of the burning Iron there would be another substance, and consequently one substance should be in another, and so there would be a penetration of dimensions; which is absurd.

Thirdly, He saies: When the Iron becomes red hot, either the substance of the fire comes into the Iron from without, or it is generated in the pores thereof. He conceives neither of these can be: Not the first, because neither the Coal of the fire because it is thick, and stirs not, but lies stil, nor the flame of the fire, because of its extream thinneſs and lightneſs, can enter into the hard substance of the Iron. Moreover, if the fire entred into the Substance of the Iron, when the Iron cools, the flame that went in should come out again: but no man (he saies) did ever see fire fly or go out of a cooling Iron. Also (he saies) the latter is impossible, because the substance of the Iron should be turned into the substance of the Fire; which is false, because the Iron remains Iron stil.

Fourthly, If the Iron became fire, it should lose its Heavineſs, Hardneſs, and Consistency.

Fiftly, A Substance is a Beeing subsisting by it self, not existing in another thing, nor inhering in any thing as its subject. But the fire by it self no where subsists, but is alwaies in some other thing, as in its subject, after the manner of accidents; and its subject taken away wherein it sticks, there is no such thing as Fire. *Ergo* it is an Accident.

Sixtly. Every Body of it self hath Quantity: for Quantity springs from matter, and the determination thereof from the form: But Fire hath neither it self any Quantity, nor hath it any determinate figure, but it hath only the Figure and Quantity of the subject wherein it inheres, as other accidents. Therefore it is no Body.

But this Error *Julius Cæsar Scaliger* long since observed and refuted in *Cardan, Exercit.* 10. For nothing is accidentally in any thing, which is not essentially, primarily, and of it self in some other; since every accident flows from a certain substance. And therefore since Heat is accidentally in the Iron, of necessity there must be a substance wherein it is primarily, and by which the Iron becomes hot: But such there can be none but the Fire. And if fire be a Quality, its first and proper subject must be some substance. But those reasons whereby *Fienus* was brought into that opinion are so slight, that I wonder so learned a man should thereby be moved so to hold.

For, in the first place, we deny that the firineſs in the Wood, Iron, Furnace, Smoak, receives more and less. But that the fire sometimes burnes more, sometimes less, happens by reason of the application thereof to the Patient. For Virtue united is stronger, and therefore Fire in a compact substance, as Iron, burnes more than in a thin substance, as Stubble or Straw.

To the second I answer: That Smiths can tell that Iron is porous; and therefore the fire can easily insinuate it self thereinto. And whereas *Fienus* denies the Iron to have pores; that is contrary to sense: for Smiths know how to distinguish the sorts of Iron, and discern Iron from Steel by the variety of the pores. Nor is that of any moment which he further objects, that if the fire were only in the pores of the Iron, the solid parts thereof should not burn, nor would the Iron be light all over, many parts thereof would be dark. For indeed

Fienus

Fienus was ignorant of the nature of the small individual Bodikies or Atomes, nor did he consider what dayly happens in Nature. For if Water can so penetrate into all the smallest parts of Wood, that there shall be no part thereof which is not moistened; Why may not the moist subtile fire much more pierce the Iron? And therefore to his third Argument we Answer, That the substance of the Fire doth certainly enter the Iron from without. For although the Coal it self stir not, and enter not into the Iron; yet the fire which is in the coal exhales in smal Atomes, and insinuates it self into the Iron. And the thinness of the flame does not hinder the same, but rather help it to enter the hard substance of the Iron. And when the Iron cools again, then the fire exhales out of it; which though it be not discerned by our bodily eyes (for who can see the pure Elements of Fire and Air?) yet Philosophers discern it sufficiently by the effect.

To the fourth I answer, the Iron is not made Fire, but it receives the same. Which while it does, it loses indeed its hardness and consistency, so that it may be bent and beaten by the Hammer, yea, and it may be melted.

To the fift I say; It is false that Fire no where exists by it self, but is alwaies in some other thing as a subject; which the sense teaches. And although fire be in the Iron; yet is it not there as an accident in its subject; just as when water is in a Vessel, it is not there as in a Subject.

To the sixt I answer; That the Elements of themselves have no determinate figure nor quantity, but they are determined and receive figure from the things which compass them about.

Contrariwise, Cold Atomes having no hot body mixed with them, being abundant in the Air in the Winter time, they cause extream cold, and congeal al bodies whereinto they insinuate themselves. *Refrigeration.*

Nor did the Ancients only teach, That these first Atomes of the Elements did variously spread themselves up and down, and penetrate into other bodies; but that of them also mixt Bodies were made; and they held them to be nevertheless immutable, and to retain their own Nature however they were mixed, and being separated from the things wherewith they were mixed they held their Nature entire as before. For thus *Lucretus* writes in his Second Book. *Of the Elementary Atomes mixture is made.*

What came from Earth goes back to Earth again,
And Heavenly parts do fly to Heav'n amain.
Nor does grim Death consume our Bodies so
As to destroy the Matter, but unsew
The joyned Parts.

Most Meteors (truly) are no other than a mass of Elementary Atomes variously congregated. For Exhalations and Vapors are not continued bodies, as is commonly thought, but crowds of infinite Atomes; which is manifest from the vapors arising from water which heats over the fire. For these though far off they seem to be a continued body, yet he which is neer at hand, or who walks on a Mountain top when the Air is misty, may even discern with his eyes that these vapors are not continued Bodies, but a throng of Atomes. A Cloud is nothing else but an infinite multitude of Atomes. For as when we see a smoak ascend from burning Pitch or any other thing, we think afar off that it is a continued united body; but if we come neerer and diligently look upon the smoak, we see that it is no continued, no nor contiguous body neither; and so it is with Clouds, which until the smal bodies are again joyned together (which happens in Rain and Snow) they are no continued bodies, but many millions of millions of petty Atomes or smallest bodies. And Clouds as they are of divers kinds, so when they grow together again divers things are bred of them, as Rain, Snow, Hail, Winds, Lightnings, and other Meteors so called. Somtimes nevertheless the Atomes of Bodies perfectly mixed are mingled amongst the Meteors. *The Meteors are made of Atomes.* *A Cloud.*

For there are (in the second place) Atomes of another kind besides the Elementary (which if any man wil term first mixt bodies, he may do as he please) into which as similar parts other compound bodies are resolved. And indeed in the mixture of Natural things, or that which happens in lifeless things, these bodies of which the mixt things consist are so broken and divided into smal particles, as that none of them can be discerned and known by it self. Also in al fermentations and digestions and coctions, which are made by Nature or Art, nothing is done but to reduce things into their smallest parts, and unite them as neerly as may be. Contrariwise, the Resolution of Natural Bodies, both that which is done by Nature, and that performed by Art, is nothing but the resolving of them into their smallest parts or Atomes. *The second kind of Atomes.*

But

Chymical Operations prove Atomes.

But Chymical Resolutions do in a special manner discover that there are Atomes, and teach sufficiently what little bodies there are. So Spirit of Wine pierces through writing paper four times double into the Alembick; and in Distillations and Sublimations such Atomes are raised from Plants and Minerals into the Alembick or Recipient, many millions whereof nevertheless when they joyn together again do sometimes hardly make one drop or sensible quantity of Liquor. Nor let any man here perswade himself when he sees a vapor rise out of water or Spirit of wine, or a Smoak arise out of Pitch, Sulphur, or burning wood, that these bodies are changed into Air; but the water, spirit of wine, and other bodies, are resolved into the smallest Atomes, which when they joyn together again, they turn to water, spirit of wine, or some other body again; which the Alembicks of Chymists and their Recipients do teach. Also whiles spirit of Vitriol and other Spirits are distilled, the Recipient Vessel is often ful of such smal, but not yet smallest bodies for two or three daies together, and every moment some millions of such bodies are present and follow one another. Yet a smal quantity of Liquor comes of them when they meet and are condensed; so that those Atomes which are present at the same moment, of which nevertheless there are some millions, do hardly constitute one drop. We see the same in other Resolutions. If a man set on fire a little bit of Pitch, and suppress the flame, an huge space of Air is filled with the smoak thereof, which is no one continued body, but a multitude of little Atomes or smal bodies. And what difference there is betwixt a body compact and resolved into Atomes, we may learn only by the putting out of a Candle. For if one blow out a burning Candle, the smoaking Snuf, which is hardly so big as a Pease, does presently send forth so great a quantity of Atomes that a great part of the Air is filled therewith. So flower of Brimstone melts into Brimstone; Mercury precipitate, or sublimate, or however resolved, does return again to living and running Quick-silver. So the water wherein Metal is dissolved, although it seem cleer water, and is so exactly mixed that it wil pass through a paper: yet the Metal preserves its own nature therein entire, and is easily precipitated to the bottom in form of a most very fine pouder, which is afterwards melted into a Metal again. So also if one Mass be made of Gold and Silver melted together, and they be so mingled in their smallest Atomes that no man would think them but one simple body; yet in the mean while in those smallest Atomes each Metal preserves its form and nature, and may be separated by *Aqua fortis*, and reduced into its former Nature. Hence the cause of many Chymical Operations and things done in Chymistry may be rendred. If to Lead any way calcined you pour distilled Vinegar, the Lead is indeed dissolved in the Vinegar, but the salt of the Vinegar unites its self to the Lead, so that if it be drawn off by distilling, it comes away quite without tast, the salt of the Vinegar remaining with the Lead, whence comes that same sweet mixt body which they cal *Saccharum Saturni*, or Sugar of Lead. So if Crabs-eyes, Corals, Pearls, be dissolved by Vinegar or other acid Liquors, and be reduced to pouder, so that they may be also strained through a paper, and the salt of those acid Liquors by reason of the similitude joyns it self with the bodies dissolved (so that if it be distilled it cannot be separated without much ado) yet if into the solution you drop Oyl of Tartar made by *Deliquium*, the salt of Tartar does by similitude unite it self to the salt of Vinegar, and the dissolved Pearl or Coral is precipitated to the Bottom. So if to Quick-silver you pour Oyl of Vitriol or Sulphur, the Quick-silver is dissolved in them, but the salt which is in those Spirits is united to the Quick-silver, whence arises Mercury precipitate, which hath therefore such a corrosive faculty. Of Quick-silver, Vitriol, Salt, is made *Mercurius sublimatus*. Of Mercury and Sulphur sublimed together, is made *Cinnabaris*. Thus Metals are reduced into pouder when being dissolved in corrosive Liquors they are precipitated to the bottom. Yet they return and are reduced into their former Nature, that Body or Salt being taken away which they borrowed from the Solvent, which Operation is called Reduction. Which may be performed divers waies. Mercury precipitate if it be rubbed in a Mortar with Oyl of Tartar or Salt of Tartar dissolved *per deliquium*, the Salt which cleaves to the Mercury is united to the Salt of Tartar, and forsakes the Mercury, whereupon it turns to Quick silver again. So, if Mercury sublimate be mixed with Quicklime, and put into a Retort, the Salt of Vitriol, and the common Salt which is in the sublimate, sticks to the live or unslak'd Lime, and so the Mercury returns to its former Nature, and becomes Quick-silver again. The Calces or Pouders of Metals are turned into molten Metals when the Salt mixed therewith is dissipated by a strong fire, yet it is done sooner if some of those Pouders they cal melting Pouders be mixed therewith. For the Salts of which those melting Pouders are made do draw to them the Salt which adheres to the calcined Metal; from which when they are freed, the Atomes of the Metal by reason of similitude unite themselves, and so return into their ancient

Precipitation.

Reduction.

Body

Body and shape. And indeed, how many external forms Bodies natural being mixed with others may put on (their substantial form remaining safe and sound) even Mercury alone may teach us, which puts on so many external forms, that it may be wel called Many-shap'd Mercury. 'Tis changed into a clear water, into a Liquor like Butter; 'tis sublimated, precipitated, reduced into pouder, into Glass, the likeness of Lead, Gold, Silver, so that it may be wrought into Plates, and I know not how many forms besides; al which nevertheless it laies down, if that which is mingled with it be therefrom separated. *Many-shap'd Mercury.*

This Doctrine also of Atomes is manifestly confirmed by anointings with Mercury and Fumigations made thereof; wherein the Quick-silver being reduced into smal Atomes penetrates the whol Body to the very jaws and mouth where it may be received by pieces of Gold held in the same. Yea, and it hath been found that after nointings with Mercury, Quick-silver hath been collected in the Cavities of the Veins and Bones.

Yea, There are Atomes not only of inanimate Bodies, but also of some animate bodies: and the Soul it self may sometimes lurk and preserve it self in such smal bodies; as we shal hereafter shew when we treat of the Spontaneous Original of living things; and upon this Doctrine of Atomes the most learned *Fortunius Licetus* hath built in a manner al his Treatise of the Spontaneous Original of live things. Of which we shal speak in its place. *Atomes of Animate Bodies.*

Plants (truly) do manifestly declare that there are Atomes. For who would beleeve that in cleer and transparent Wine there were a stony substance, unless it appeared by separation, whiles the Tartar separated from the Wine sticks to the sides of the Vessels? And matter unfit to nourish the body being thrust into the joynts stirs up arthritick pains, and there at length it grows into a kind of stoney substance. The Generation also of other diseases shews the same: For seeing many superfluous things unfit to nourish are taken in with our meat, they though they are bitter, and sowr, and salt, and otherwise pomaint, strong and different; yet (as *Hippocrates* saies, *de Prisca Medicina*) being mixed and mutually tempered together they are neither perceived, nor do they hurt a man: but when any of them is separated and by it self, then it becomes apparent, and troubles a Man. *The Atomes of Plants.*

Also the Atomes of Purging Medicaments do make the Milk purging, as also *Hippocrates* saies in 6. *Epidem. com.* 5. *text.* 33. If a woman or a she Goat eat Elaterium or the wild Cucumer, their yong ones are purged. For although as we have also said in our *tr. de Dissens. chymicor. cum Aristotelic. & Galen.* a purging Plant eaten by a shee Goat is digested in her stomach, and mingled with the Chyle, that Chyle is turned to Blood, that Blood in the Goats Dugs becomes Milk, this Milk is drunk by the Nurse, and there are so many mutations: yet in all these the Atomes of the purging Plants remain intire, and keep their Vertues. *The Atomes of purgatives*

Milk also it self, though it seem but one body, yet the Whey, Butter, and Cheese do shew being separated, that there were divers smal Bodies mingled together therein. So the Blood of Animals, although it seems to be one homogeneal Body, there are nevertheless therein not only divers parts which afford nourishment to different Members; but also if it be distilled, Volatile Salt which before did not shew it self sticks in great quantity to the Receiver. Which also happens if the Horns and Bones of Animals be distilled.

Yea, and the consideration of whol entire Animals may bring us to the knowledg of Atomes. *Aristotle* in the 5. *Histor. Animal. cap.* 3. writes that in old Wax and in Wood a certain Animal is bred (which is the least of al living things) called *Acari*. There are also a sort of Lice called *Sirones*, so smal that they cannot be seen but by a sharp sight, and in an augmenting Glass. Yet these are Animals, *ergo* they have an animal, motive, nutritive, and sensitive faculty in an Organical Body made up of very many Organs. They draw, concoct, assimilate their nourishment, and are moved. They have therefore animal Spirits, and natural, which are themselves also bodies; they have Organs wherein they are generated, and wherein they are contained. And al these again if we divide them into their first and smallest Atomes or bodies, how many thousand parts wil they make? and if the little Creature Acari, or a smal Louse, be divided into so many thousand parts, how very exceeding little must those parts be?

And although those Atomes be so exceeding smal; yet the essential forms of things remain in them entire, as was lately said, and experience it self does witness. For if Gold and Silver be melted together, the Atomes of the Gold and Silver are so mingled in their smallest parts, that no sense can discern the one from the other. Yet both of them do retain their forms entire. Which appears hereby in that if you put *Aqua fortis* upon the said *Atomes retain the forms of things.*

Mass, the Silver melts and turns into the Liquor, but the Gold remains in form of a Pouder. If the dissolved Silver be precipitate it settles to the bottom in form of a most delicate fine Pouder. Each of these Pouders molten by themselves do return into their former shapes of Gold and Silver. So if Quick-silver be sublimed, precipitated, turned to water, and undergo other changes, according to the various mixture of the Atomes whereinto it is resolved with other things; yet it alwaies retains its own essential form, is easily separated from the Bodies wherewith it is mixed, and returns into its old shape of running Quick-silver. Nor does this betide in Metals only, but also in Vegetables or Plants. For when distilled Waters and Spirits are made by Chymists, insensible Atomes arise out of the Plants, so that in the *Cucurbita* they cannot any waies be discerned; but when they joyn together in the Alembick, and turn to Liquor, they again shew themselves in their likeness, whiles one is Spirit of Wine, another of Juniper, &c. And if a Goat be nourished with certain purgative Herbs, and a Nurse drink the Milk of the Goat, it wil purge the Infant which sucks that Nurses Milk; as was said before out of *Hippocrat. 6. Epidem. com. 5. text. 33.*

That most learned Peripatetick *Jacobus Schegkius* acknowledged the truth of this thing, when in *Lib. 2. de Occult. Medic. facult. cap. 1.* he thus wrote, *The beating of a thing into a most fine pouder does not necessarily corrupt the substance thereof, seeing it is an accident of an accident for that which is continual to be divided into very smal bodies.* And a little after; *It does not follow that the substance is abolished, if a man shall say that Medicaments beaten into pouder are effectual in our bodies.*

Atomes are determinate. Howbeit, Atomes have their Laws from Nature, and doubtless the Atomes of Fire are more subtile than those of Earth, although we cannot discern so much. For so the case stands with Natural things that the forms consist not save in a certain quantity; and as they diffuse not themselves beyond their Natural bounds; so they cannot be conserved save in a certain quantity. This also *Franciscus Aguilonius* observed, who in the 5. B. of his Opticks, Propos. 8. declared this thing in the example of Light, when he wrote; Though there is not a smallest in quantity, yet Light hath a smallest in Nature, that is to say, so smal a Light that it cannot be smaller without perishing. After which manner there are also the smallest among Natural Bodies; which if they be any more divided they lose their form and essence. For as Bodies towards their natural subsistency do require some bulk of quantity, which is nothing but the measure of corporeal substance; even so Qualities also (unless they be in some degree of excellency) they perish of their own accord. And in Propos. 15. We affirm that Light cannot of its own strength and by it self exist solitarily in any degree whatsoever, but that there is a certain limit of smalness, beyond which we cannot proceed by dividing without the destruction thereof, which therefore we may not unfitly cal the *minimum naturale* of Light: but if it be joyned to a greater Light, although it be smal, nothing hinders but by help thereof it may be sustained, provided both together do at least attain to the *minimum naturale*, or smallest natural quantity of Light. Moreover, this imbecillity of subsisting is not proper to these Qualities alone, which admit the diversity of greater and lesser, but also common to al Bodies which vary their magnitude. For as these without some bulk, so they without some degree of excellency cannot free themselves from destruction. For being attenuated beyond their strength they fal to nothing and perish, no contrary thing destroying them, but only through defect of that measure, which being an indispensable Law of Nature, is requisite to the proper maintenance of each one. But what he saies of Qualities may be said much more of Forms from which the Qualities flow.

Things smallest in Nature.

Now those disputes against Atomes concerning the infinite division of that which is continued of indivisible Lines, are disputed not from Natural but Mathematical Principles. For the Question is not here (as was said before) Whether a thing continued be perpetually divisible Mathematically? but, Whether or no Nature in her Generation and resolution of Bodies does not stop at some smallest Bodies, than which there are not, nor can be any smaller.

CHAP.

Chap. 2. *Of Mixture.*

SInce the Doctrine of Mixture is exceeding neceſſary rightly to underſtand the Generation of al Natural Things, and the Foundation wel-neer of al Natural Philoſophy; it is worth our Labor duly to explain the ſame. Which that we may the better do, we are to know in the firſt place that the term *Mixture* hath ſundry acceptations. For (as *Thomas Eraſtus, Diſput.* 2. *Contra Paracelſ. part* 2. *p.* 195. writes) ſomtimes it ſignifies an Heap and Maſs of things blended together, as of Rye, Wheat, and other ſuch like things which keep their ſurface and Integrity. Somtimes it ſignifies the compoſition of two or three, or more Bodies, ſo confuſed together, that though each retain its own Nature, and they may be ſeparated again, yet one Body is made up of al. Such is *Crama*, which is made of Wine and Water mixed; which is not one in Form, but in continuation only. For although neither the Wine nor the Water be ſeparable by their bounds, yet they are both ſo contained under their Natural Form as Gold is in Silver, which may be ſeparated by *Aqua fortis*. Such a Body is Honey and Wine, Honey and Water, and infinite others compounded by Art. Thirdly, it is taken for a Body compounded of divers things, ſo that of all one thing is made, of a different Nature from al the Ingredients, and having a form quite different from their forms. And things ſo mixed are truly ſaid to be mixt bodies. The firſt manner (ſince therein no real mixture is made, but dry things are only blended together, which makes no difficulty in our minds) *Julius Cæſar Scaliger* omits, and propounds other three, *Exercitat.* 101. *Sect.* 1. There are (ſaith he) three Manners, Degrees, or Sorts of Mixture. The firſt is of thoſe things which after they are blended may again be ſeparated; as a mixture of water and wine. For *Pliny* reports they are ſeparated with Veſſels of Ivy as he had it from *Cato*; and we do it with a cloth. The other manner is as it happens in thoſe bodies natural which we cal imperfectly mixed, of which there are two degrees: The other more weak, as of a Cloud, Rain, Wind, Hail, Snow, Dew, Hoar-froaſt, and ſuch like. For they are exhalations mixt of divers Elements which may eaſily be diſſolved. But they hang together more cloſely than thoſe of the firſt ſort. The other degree is of a firmer union; as in clods of Earth and ſtones. For the parts of theſe are not eaſily ſeparated one from another. Yet they cal them rather mixt Bodies than by any other nobler Appellation, becauſe they ſeem to them to be things only begun. The third Mixture is of ſuch things as ſome are pleaſed after a peculiar manner to term Mixt Bodies. Such are Vegetable and Senſitive things.

Mixture, what it ſignifies.

Now concerning theſe three Manners, the Queſtion is, Whether they are in al mixt bodies made after one and the ſame manner. Which that we may rightly unfold we muſt know in the firſt place what Mixture is. Now *Ariſtotle* defines it to be the Union of things mixable after they are altered. And *Scaliger* in the place fore-alleadged; That it is the motion of Atomes or ſmalleſt Particles of Bodies to a mutual Contact, ſo as they may become one. And he further explains his meaning, and that rightly, how that every thing that is, is one, not only by continuation and privation of pure contiguity, but by act alſo, by vertue whereof it comes to paſs that thoſe parts become one body. Now by Act he means the Form, by which it comes to paſs that thoſe parts which by their own nature and aptitude might come together to an Union, are become actually one. And he concludes rightly, That thoſe things which are not one Beeing formally, but by accident only (as an Heap of Beans and Oats blended is one) are not properly mixt bodies, nor ought ſo to be called, but things jumbled, as Wine and Water, Silver and Gold; ſince ſuch things are not formally one, but ſo many things as there are parts within and without, and only one by accident; which though it be leſs manifeſt to the ſenſes, yet is it not hid to the underſtanding of wiſe Men; ſeeing they may eaſily be ſeparated, as Wine and Water by Ivy Veſſels, and by cloaths; and Silver and Gold by *Aqua fortis* ſo called.

What mixture is.

But by al that hath been ſaid the difficulty is not quite removed, nor the Nature of Mixture ſufficiently explained; but two knots do remain as yet to be untied, which being rightly unfolded they bring great Light to Natural Philoſophy and Phyſick. For although we muſt needs grant, that nothing is truly mixed but what is formally one; yet the queſtion ſtill remains: Firſt, Whether it be neceſſary that the mixable bodies which are united by vertue of one Form, and grow together into one mixed Body, ſhould loſe their own Forms? or, Whether in the mixed body they may al under another form retain their own forms ſtil? Secondly, Whether the Elements only are mixable, and every reſolution into the ſmalleſt

particles made in reference to Mixture does alwaies proceed so far as to the Elements? or whether other bodies more noble than the Elements may properly be said to be mixed? Both which Questions must be explained.

Whether things mixable do in the mixture retain their forms?

As to the first Question, That the same may be rightly explained, we wil only enquire concerning the Elements. For concerning them there is no doubt but that they are rightly mixed; but as touching other Bodies the matter is questionable. But whatsoever shal be said of the Elements, that hath also undoubtedly place in al other mixable bodies. Now there are chiefly two Opinions concerning Mixture; the one held by well-nigh al the Ancients before *Aristotle*, as *Empedocles*, *Democritus*, *Anaxagoras*, *Hippocrates*, yea, and by very many Philosophers since *Aristotle*, who al held that Generation and Corruption are made by the Conjunction and Separation of Atomes, and that the Bodies mixed do retain their forms entire in the thing made up of them. Which manifestly appears out of *Hippocrates*, *Lib.* 1. *de Victus ratione*, where he writes: *What I mean by Generation and Corruption I must explain for the sakes of many, viz. To be mixed and separated. Now thus the matter stands: To be generated, and to be mingled are all one, and to be separated and corrupted are all one.* According to whose mind, as I said before, *Jul. Cæsar Scaliger*, *Exercit.* 101. defines Mixtion; That it is the motion of Atomes to the mutual contact one of another, that they may be united. The other is the Definition of *Aristotle*. For he only separated from the Ancients in this point. For thus in the 1. *de Gener. & cor. cap.* 10. he writes against *Empedocles*: *We must not say, That such things as are mixed are mingled by their smal parts, which still retain their own nature. For that would be a composition, but not a temperature or mixture, nor would the part be of the same nature with the whol. We say, That if a thing be mixt the parts thereof are one like another, even as every part of water is water. But if mixture be a composition according to the smal parts, none of these things does happen, but that is only a mixture so appearing to the sense, and that which a dim-sighted man will account mixed, a quick sighted man will discern not to be mixed.* He teaches the same in the 2. *de generat. & corrupt. cap.* 7. *pag.* 47. the sense of which place *Toletus* thus propounds: *He reproves this manner of mixture* (which *Empedocles* supposed) *because one inconvenience follows*, viz. *That out of every part of the mixt body the four Elements could not be extracted, and so every part of the mixt body is not mixed: the Consequence is cleared, because as out of every part of a wall cannot be taken stones and bricks, because where the one is, the other is not: so truly it will be in a mixt body, which is made after the same manner of the Elements.* And thus indeed *Aristotle* opposes the Opinion of the Ancients; but he so propounded his own Opinion that hitherto for so many Ages there hath been Civil War amongst his Expositors, what his Opinion was, or how it is to be explained; whiles some (as *Averrhoes*) do hold that as wel the substantial Forms as the Qualities of the Elements do remain actually in the body mixed, only broken, allaied, and reduced to a mediocrity. Others (as *Scotus*) do teach that the forms and qualities of the Elements do quite perish in the mixture, and that a new form of the mixt body is generated, and a new quality, which is the temperature of the mixt body. Others (as most of the Latins) do conceive, That the forms of the Elements are no waies preserved in the mixt body, neither entire nor broken, yet they hold the Qualities remain in the mixt body, but broken and reduced to a mediocrity. Whose contentions to set down in this place is no part of my business. They may be read in *Zabarella* his Book of Mixture, in *Tolet. Lib.* 1. *de generat. et corrupt. cap.* 10. and other Expositors of *Aristotle* every where.

The Opinion of those Authors who hold the Forms remain in the mixt Bodies.

There have been found in the mean while most learned men of no smal note, who being moved with the evidence of the thing it self, have embraced the Opinion of the Ancients, as *Philoponus*, *Albertus*, *Aureolus*, *Zimara*; and amongst Physitians *Avicenna*, *Fernelius*, and very many more, who so stoutly defend the Opinion of the Ancients that some of them write, Whoever read their Arguments (if he be not a Mil-stone) wil consent, and those that think otherwise play the Sophisters, abuse the Works of Nature, and destroy and defile the Splendor of the Ancient Discipline. And especially *Avicenna* comes up directly to the mind of the Ancients, and holds, That the Elements in mixt Bodies do retain their Forms perfect and entire, howbeit divided and cut into very smal parts, so that their particles composed and knit together in a certain order do mutually cohere one with another. *Fernelius* follows *Avicenna*, who *Lib.* 2. *Physiolog. cap.* 6. cals the Opinion of those that hold the contrary, a childish and vain, nay, a monstrous Opinion; and he judges that those who so think have contemned the Philosophy of the Ancients. And they do indeed al of them wel, in that they adhere firmly to the Opinion of the Ancients, being moved thereto by most firm Reasons: but herein they take pains to no purpose, whiles they would make

this

this to have been the Opinion of *Aristotle*; since *Aristotle* in expres's words relinquishes the Ancients in their Opinion, as appears in that place lately alleadged. Yea, and very many others who differ from the Ancients saw this Truth, and nothing but the Authority of *Aristotle* hindred them from imbracing the same; and if the Authority of *Aristotle* be set aside, and the point debated only by reason, and no vain labor bestowed how to reconcile this Doctrine with *Aristotle*'s words, that is, Truth with Falshood, the case is very plain. Yea, *Aristotle* himself comes to this Opinion against his wil, whiles at the end of his 1. Book *de Ortu & Interitu*, he defines Mixture to be the Union of things mixable, being altered. For when he saies the Union of things altered, he intimates that the things mixed do not perish, but remain in the body mixed. For if they are altered and mixed they do not perish. Nor does the word Union oppose this Opinion, as *Zabarella* conceits in *cap.* 1. *de Mist.* but rather confirms the same. For Union is the Copulation of such things as have a real Being, but not of things that perish. And although of many things one be made: yet neither is it necessary that those simples should perish, nor is it a meer aggregation or blending, but the simples by a superior form are reduced into one body. And this Doctrine of the Ancients, viz. That the Elements and simple Bodies do keep their natures entire in the Compounds, is the key (in a manner) to al Natural Philosophy, and the greatest part of Chymistry and Physick.

Contrariwise, That only Opinion of *Aristotle*, That the Simples do not retain their Natures in mixt Bodies, hath cast the Expositors of *Aristotle* into Labyrinths and inextricable Controversies, and hath been brought into Natural Philosophy to the great dammage of Physick; which being rejected all things become plain and easie.

The ancient Philosophers, and late Authors which follow them, have been induced to imbrace this Opinion by very strong reasons. For first of al, the Nature of Mixture shews as much, since things that perish cannot be said to be mixed: which *Aristotle* himself in the end of *Lib.* 1. *de Ortu & Interitu* acknowledges. Nor could he do otherwise. For since (as in *Metaph. Lib.* 5. *text.* 3.) he declares, That Elements are that of which existing things consist; it must needs be that these Elements (if they were Elements) must abide and exist in the mixt Body. *Arguments for this Opinion.*

Moreover, Since Action presupposes Act, and in mixt bodies the actions of the Elements are apparent; of necessity they must be actually in them. Not to speak of others, *Aristotle* himself, *Lib.* 1. *de Cælo*, writes, That a mixt Body is moved according to the sway of the prevailing Element.

Finally, The Resolution of mixt Bodies into their Elements shews the same. For mixt bodies are resolved into the Elements; and *Aristotle* himself in 1. *de generat. & corrup. text.* 84. saies, That the things mixable may be separated again from the mixt body. And if so, then were they actually in the mixed body.

The force of which Argument is such, That those who have labored to answer the same, have shamefully foiled themselves. For the Conimbricensian Collegiates, while they deny that while Woods are burnt they are resolved into the four Elements, and deny that the water which drops out of the said wood, and distilled waters, are true water, they resist not only *Aristotle* himself, and other Peripatericks, but also their very Senses. For suppose that Liquor which drops out of burning Wood, or from an Alembick, is not pure water: yet our Senses, and the separation which is easily made, do witness that the greatest part thereof is water. And after this reckoning there should be no Element of Water in the whol World; since it is no where found pure. But others left they should go against their own Senses, do indeed grant that mixt bodies are resolved into the Elements, but they foolishly hold, that not the same Elements in number, but only the same sort of Elements come out of the mixt body; which is founded upon no reason, but is only hatched to palliate an absurd Opinion, yea, and it is repugnant to Reason and Experience. For when they hold that Elements return out of the mixt body by reason of the action of a like Element, whereby they recover what they lost in the mixture; how I pray you, in distillations and burnings can Water and Earth be extracted out of the Compound? since Fire by acting upon the mixt body introduces nothing that is watry or earthy, yea, the action of fire is adverse to water and earth, so far is it from augmenting or perfecting the same. The only agent in combustions is fire: and the force thereof equally affects al the parts of the mixt body, and yet nevertheless it brings out some hot, others cold, others moist, others dry, others bitter, others sweet, others other waies differing: which since they cannot proceed from one only action of fire, verily we must believe they were before in the mixt body.

And

And which way soever they turn themselves who hold the contrary Opinion, yet they can no waies dis-intangle themselves. For either the Form remains in the mixt body, or it does not remain. If it remain, it remains either entire, or broken.

He who holds they remain intire, consents with the Ancients. But *Averrhoes* and *Zabarella* hold they remain broken. But what they bring concerning the Refraction or breaking of the Forms, is a meer figment; and their Opinion who hold the forms of the Elements are capable of more or less are sufficiently refuted from the Latins disputing against the Opinion of *Averrhoes*; nor have they ever brought any so much as a probable reason for their Opinion, but have only simply and barely affirmed, that Forms have certain degrees, some of which may be taken away, and the rest remain. For the whol Nature of the Form consists in that which cannot be divided, nor does any Form receive more or less, but where ever it is, either it is totally there, or not at al.

But they which hold the Forms do not remain in the Body mixed, and that nothing remains but the matter, are very absurd and almost ridiculous. For what mixture is there where nothing remains? For since the Elements have no other matter than the first, and the first matter is common to al the Elements, I cannot say that one mixt body hath more fire than air. For whatsoever is, is by its form. And therefore if the Elements are not in the mixt body by their form, they are not there at al. And thus a mixt Body in respect of the Elements should be as simple as the Elements themselves; because although the matter be from the four Elements; yet because the Matter of Fire, Air, Water, Earth, does not differ, and the Form (according to their Opinion) of Fire, Air, Water, Earth, should be no longer present, the mixt body so called must needs be simple.

And that we may also consider what is wont to be objected to the contrary; if any shal ask, What were the Motives which caused *Aristotle* to forsake the Opinion of the Ancients commonly held in his time, we cannot find any of moment, save that which he chiefly propounds, in 1. *de Generat. & Corrupt. cap.* 7. and that is this: That he conceives from the Opinion of the Ancients this absurdity follows, That every part of a mixt body should not be mixed, and that out of every part of a mixt body the four Elements could not be extracted. But the Ancients wil answer, That this ought not to be done, and that this is *Aristotle's* Hypothesis, and that he laies that as a Foundation which is the matter in Controversie. For this Assertion seems contrary to the nature of mixture. For if there be a mixture, those things which are mingled must needs be simples. Nor is it necessary that those Simples should be mixed, but at last in the resolution we must of necessity come to Simples.

Others also do ad other Reasons. *Scaliger*, *Exercit.* 16. *Sect.* 3. The Forms remaining (saies he) mixture (according to *Aristotle*) should be but an heap; as it is in dry bodies. For the Natural Quantity of every smal part follows the existence thereof, but not continuation, for so should they be really the Atomes of *Democritus*. But *Scaliger* whiles he regards somtimes truth, other whiles Authority, contradicts himself, and answers this Argument, *Exercit.* 101. while he writes; That these parts retain their forms, but lose the prescription of their bounds, and so they are not a meer heap, but do make a mixt body. For that is false which some object, That things of different sorts cannot be continued. For whiles the Elements are united under the Dominion of one Form, they are really continued. Nor is it absurd (as the same *Scaliger* writes in the same place) to hold that there are many forms in one continued body. For these forms are every one the act of its own Matter. Which matters because they are by Nature ordained to a more labored composition, she hath provided that their forms as wel as themselves should be mixed. But the ultimate and most excellent forms, as of a man, since they are not ordained for any further work, they only are not mixed.

Moreover, Neither is this of any great moment which some object; If the Elements should remain perfect under the dominion of another Form, it would follow that the Form of the mixt Body should be an accident; since what is added to a perfect Being actually constituted is an accident. For the answer is manifest from what hath been answered to the former Objection. For as *Scaliger* saies there, those less noble Elements and Mixables are made for the sake of the more noble, and therefore submit themselves to the Rule of the more noble form, which supervening obtains the Office, not of an accident, but of a specifick Form. But those things only which are added to those more noble bodies, which are not ordained for any further composition, are accidents.

The principal cause of mixture. Now that many have not been able to attain the truth in this point, and have erred in a matter plain enough, the chief cause is, That they knew not the true and principal Cause of mixture,

mixture, and thought that al sorts of Natural Bodies did proceed only from the mutual fight of the Elements, and their mutual action one upon another; and to use the words of *Aristotle* himself, *Lib. 2. de Generat. & Corrupt. Cap. 9. text. 54.* they attributed powers and vertues to Bodies (by which they generate most instrumentally) neglecting the cause taken from the Form. But the sole concourse of Elements makes very few sorts of natural things, and none of those more perfect Bodies: and contrary to the mind of *Aristotle*, the Expositors father upon him, that he brings the Generation of Natural Bodies only from the Elements. For he expresly holds (as was said before, *2. de generat. & corrupt. text. 40. 53. & sequent.*) that the Qualities of the Elements are only Instruments, and the principal Cause is the specifick form of every thing. The same thing *Scaliger* teaches, *Exercit. 307. Sect. 20.* Unless (saies he) the four Elements have a Governor, they wil vainly tos and be tossed. For what is it that shal mix so much Earth with the rest? And there ought to be in every motion one first Mover. For they cannot move themselves to any work, but in Compounds they are moved to mutual connexion by a more excellent Form, in bodies imperfectly mixed by an external principle. *Erastus* was forced to acknowledg the same, who although in his Disputations against *Paracelsus* he writes, *Parte altera, pag. 196.* that there are no qualities in the whol world which can change whol Bodies applied to them, besides heat and cold, moisture and driness (and that therefore these Qualities must necessarily be held the Principle of Mixtures) yet compelled by the evidence of the thing it self he ads by and by: we do not say that they are principles in such a sense, as if we held them to be the principal Causes, but we say they are Instruments without which no form can make a mixture. But being further demanded, What that form is which is the worker of mixtures? he answers, It is the Divine Command whereby in the Creation God commanded the Elements that they should orderly meet together for the Generation of things; and that the Motion of the Heavens gives no smal assistance thereto. But this answer is partly from the purpose, partly false. For the Question is not about the first Cause of things, but the immediate Cause. Nor is it yet proved that God gave this Command to the Elements, but it is the Office of the Form to marshal the Elements in a mixt body. And although God created al things, and these lower Bodies are subject to the motions and influx of the Heavens; yet God hath given Nature, by which al things are generated, which is the form of every thing, and the Soul of things animate. It shapes it self its own body, and for the making thereof draws Elements and other Bodies, disposes, unites and governs them; whence it follows that they are now formally one, and being united under that which is actually one they become themselves actually one which before were many. And therefore the Elements do not concur of themselves, but are drawn by the Forms. Whereof *Scaliger* writes excellently in *1. de Plantis*: *The Soul* (saies he) *is Nature to a living thing. She shapes for her self Hoofs, Teeth, Horns to defend life: and therefore she uses them, and knows how to use them, without any object or any phantasie. He that made the Soul gave certain precepts thereto, partly general, partly special. Those are such as pertain to her preserving her union with the Body: of which there was to be no outward Author. Careful therefore hereof she moves the Heart, concocts in the Stomach, concocts again in the Liver, perfects the nourishment in the Veins, digests in the Members, changes it into the substance of the Body, bears it, unites it, restores it, repairs it.* Yea, he speaks Divinely in his *2. de Plantis*: *That* (saies he) *which is heavy, also ascends: For that work is performed by the distributing faculty, which also lifts the Earth upwards, and drives or draws the air downwards; being Lady of the Fire and Air, by the first Command of its Creator. For I doubt not but you hold that there was not one Spirit-maker of all things, and another the Preserver of them when made; nor that he which made all things of himself, and cannot be absent from himself, can be absent from the things he hath made. God, God, my good friends, neither idle, nor busied, neither in work nor out of work; but without work, the Head, Beginning, Middle, End, and all of the Work, and that I may in one word dispatch, compass in, and surmount all, He himself, who by his most simple and indivisible Understanding of himself made the World; wherein all have attained their End and Order.*

The Opinion of Erastus touching the Cause of Mixture.

Mixture how it is made.

Nature the Handmaid of God.

All things from God.

Zabarella also saw the same Truth in part; but he could not reach the whol, being hindred by a pre-conceived Opinion, whiles in his *1. de mist. Generat. & Interitu, cap. 2.* he distinguishes betwixt the generation of a mixt animated body and an inanimate, and saies rightly, That a living Creature is not generated by the Elementary Vertue, but by Vital Heat implanted in the seed, so that in the generation of a living thing al the Qualities of the Elements are instead of matter, and the immediate Agent is the Vital Heat implanted in the Seed, being proportionable to the Element of the Stars.

The Generation of a living and lifeless mixt Body does differ.

But

But whereas he saies that a mixt Body as such is generated by Elementary heat tempered by cold as the prime Worker, working upon the two passive Qualities as Matter; that is liable to many difficulties. I say rather, hardly any perfectly mixt body is generated after that manner as *Zabarella* supposes, and that there is no such mixt thing in Nature. For what (as was lately alleadged out of *Scaliger*, *Exercitat.* 307. *Sect.* 20.) should thus collect certain portions of Elements, and what should mingle so much Earth with so much Water? Nor is there any reason to fly to the fire in this case, whereof *Scaliger* speaks in his second *de Plantis*: If the Fire unites the three other Elements as parts, what shal unite it to the three? But most likely it is, that al perfectly mixt things are either parts of an animated Body, or sorts of Natural bodies made in the first Creation, which either yet remain such in the Individuals, or are continued by a new Generation; whereof *Scaliger* most rightly in the same Exercitat. saies, That every Form of every perfectly mixt body, although it be not a Soul, as that of an Adamant, is a fift Essence far different from the four Elements. For this form in Gold, Silver, and other Metals, in Jewels and Stones, aptly disposes the Elements and such matter as is fit for it self. From which it easily appears, that what is by *Zabarella* objected, *de Mistione*, *cap.* 9. is of no moment; where he writes, If in Mixture there were made a resolution into the smalleſt parts natural, there must alwaies be equal portions of the mixable Ingredients, or they must hold the same proportion one to another. For this is no waies necessary; but the Elements concur in an unequal and most divers proportion, according as the Constitution of the mixt body requires, or as the mixture is directed by the superior Form. For a Gourd and a Cowcumber draw more Water and less Fire; and a Pitch-Tree, a Pine-Tree, and a Fir, draw more Fire and less Water.

whether a fight of the Elements is requisite in Mixture?

Moreover, This also was no smal Cause (which yet agrees almost with the former) why many erred from the Truth, because they supposed that the Elements did no otherwise concur to Mixture than by their fighting one with another. For seeing mixt bodies consist of contraries, and contraries do mutually fly one another; that they may concur and friendly agree to make up a mixt body, some have thought that this friendship and agreement could not be procured unless by fight foregoing they were reduced to a mediocrity. Which agreement of the Elements how it should be made they are at variance amongst themselves, whiles some hold that it is sufficient that their first qualities be abated, though the forms remain intire; others conceiving that both the forms and the qualities were remitted and broken. But there is simply no need of this fight; it is sufficient if they be reduced into Atomes. For then it is that things contrary do fight together and shun one another, when notable magnitudes and portions of them do concur. But when they are reduced into their smalleſt Particles or Atomes, there is either none at al, or no considerable Skirmish. Which thing is apparent by many experiments. When water is poured upon burning coals, a noise is raised by the fight of those Contraries; but not when the fiery Atomes are mingled with the Water, while the Water heats and is turned into vapors; where by the confession of al men the Atomes both of Water and Fire are contained in the Vapors, and keep the peace. So also, if water be gently heated, it receives the fiery Atomes without any fighting: but if the water grow exceeding hot, and the fiery Atomes come thronging into the Water, or particles of fire bigger than atomes, there is fighting, and great bubbling and boyling. But when the water is resolved into vapors and smalleſt atomes, although it be joyned with atomes of fire, yet no fight is observed. Oyl admits no Water, nor is mixed therewith, by reason of the contrariety of its Nature. Yet if Oyl be reduced into Atomes it wil admit Water. For examples sake, distilled Oyls do swim upon Wine and distilled Waters, and mix not therewith; but if those Oyls be first mixed with Sugar, and the Sugar afterwards dissolved in Wine or Water, the Water receives the Oyl being reduced into smal atomes, and thereby a Medicinal Wine or Water is made, having the smel, tast, and vertues of the said Oyl. After the same manner in the dissolving of Pearls, Corals, Metals, first there arises a bubbling and a noise, the bubbles ascend; but when the Connexion of these Bodies is loosened, and they are divided into Atomes, al is quiet, nor do they act any more one upon another, although each of these bodies remains under its own form, as Precipitation and reduction teaches. So also in the preparation of *Tartarum Vitriolatum*, if Spirit of Vitriol be mingled with Oyl or Salt of Tartar, there arises a mighty battle, a noise, hear, and boyling. But when these two Fighters are duly mixed in their smalleſt parts, al the Quarrel ceases, nor is there any more noise or boyling. Nor let any man object, That those smalleſt Atomes therefore fight not, because they are by their mutual action one upon another tempered and reduced to moderation. For separation and reduction do shew the contrary,

which

which teach us, that those smallest Atomes do remain and subsist under their own proper Form, and are easily (being joyned together) reduced into their ancient body again. So the Spirit of Vitriol and Salt of Tartar do in their very mixture retain their Forms entire; which even distillation shews, by means whereof the Spirit of Vitriol is again separated from the Salt of Tartar, and being separated it subsists of it self with al its forces entire. Which if it be again poured upon the Salt of Tartar it raises a new combate, until these Combatants (being mingled in their smallest parts) come to a Friendly Agreement.

Whether in mixture the Ingredients must needs be reduced into Atomes?

From al which it appears, That although contrary Principles do concur in the Generation and Nutrition of mixed Bodies; yet for their uniting there is no prime necessity of a fight, but it suffices that they concur in their smallest Atomes. And this is that which *Hippocrates* writes in *Lib. de Prisca Medicina*: In a Man there are bitter, and salt, and sweet, and sowr, and harsh, and tastless parts, and an hundred other sorts, which being mingled and mutually tempered together are neither discerned, nor do they trouble a man; that is to say, when they are reduced to their smallest Atomes, and so mingled together. But when they exist apart, that is, when many Atomes of the same kind being separated from the rest are joyned together, so that they become a conspicuous coagulated Body, then they exercise their Activity. And hereunto tend all the Digestions and Fermentations of the Chymists, viz. That Bodies which in a greater bulk were contraries may be reduced into their smallest Atomes, and afterward agree friendly together and be united.

The Eduction of Forms is rejected.

Finally, It hath been also no smal Cause of Error in many, that same vain Fiction of the Eduction of Forms, which we have elsewhere rejected. For although herein (as was said before) *Zabarella* is in the right, when he holds that the Vital Heat is the Agent in the Generation of living things (though it be not the primary Agent which is the form, but its Instrument) yet ever and anon he fals back into the common Opinion, and endeavors to reduce the Generation of living things also unto the Concourse and simple mixture of the Elements. For so (*Lib.* 1. *de Misti Generat. & Interitu, cap.* 3.) he writes, When five degrees of Heat, and six of Moisture concur, it is a convenient proportion for to educe the form of Oyl. Whereas sure it is, That Oyl is not generated by a simple concourse of Elements, but is produced by the Olive Tree. Now Olives are the Fruit of the Olive Tree, which the said Tree produces by its inbred Heat; out of them is pressed the Oyl after the same manner as out of Almonds, Nutmegs, Lin-seed, Poppy-seed, and Wine out of Grapes.

Whether the Elements only are mixed.

As to that other Question, Whether the Elements alone are mixed? or whether there are other smal Bodies or Atomes which may truly be mixed? The most (truly) of *Aristotle's* Expositors do conclude also from that supposition of theirs whereby they hold, That al things are made by the mutual action of the Elements one upon another; that only the Elements also are mixed, and that there is no mixture in which there is not a resolution as far as to the Elements. But he that shal diligently consider what is dayly done in Nature, will observe that this is not alwaies necessary. The case (truly) is plain in those less perfect Mixtures; since Natural Bodies do retain their perfect Forms in them, as is cleer in Metals dissolved in *Aqua fortis*. Nor yet is it necessary in perfect Mistion. And I conceive that it is manifest in Plants and Animals. For neither are they nourished with pure Elements, but with other mixt bodies created for their sakes. A man is nourished with blood, and in that Nutrition which is a true Mixture and substantial mutation blood is not first turned into Elements, that of them flesh may be made, bones, &c. Blood is made of Chyle, Chyle of the meats we eat. In which mutations there is no resolution into Elements, but as the next matter of a Bone, Flesh, &c. is blood: so the matter of Blood is Chyle; the matter of Chyle is Bread, &c. And there are many Documents of this matter. For if in the stomach meat and drink were resolved into the Elements, no Form or Quality of things which are used in meat would remain; whereas nevertheless meats which have a purging faculty may turn to blood, and so to Milk having the like purging Faculty, which qualities could not remain in the simple Elements, if meats were resolved into them. And many Diseases arising from the use of naughty meats do more than sufficiently declare that there is no resolution as far as to the Elements in the corruption of Meat and generation of Nutriment. For al the more ignoble mixt bodies are matter for the more noble. Thus *Hippocrates* writes of Plants: Such things as grow out of the Earth and are sown in the Earth, when they come into the ground every one draws that which in the Earth is most suitable to its own nature. Now there is in the Earth both tart, and bitter, and sweet, and salt, and such like. First therefore it draws much thereout which is accommodate to its nature, and then also it draws other parts.

Most renowned Philosophers and Physitians content with *Hippocrates* Not to speak now of others, *Thomas Erastus* in *defens. thes. de saporibus* writes; Al Medicaments in a manner do not consist primarily of the Elements, but are compounded of things formerly mixed, and that many times. *Galen* shews that the body of Man is compounded, not of the four Elements, but of the four Humors, as the immediate matter of its Generation. Now it is again apparent that these Humors are made of the Meat and Drink, which are also themselves evidently made of the Juyces of the Earth. For Animals are nourished by Plants, Plants draw out of the Earth juyce familiar to them, as bitter, sweet, sowr, because of them the Nature of each properly exists. The Seeds (truly) sown in the ground while they draw to themselves profitable and convenient Nutriment they draw only such juyce as is compounded of the Elements.

And therefore those bodies also of which these are made, although they are termed the smallest bodies, yet are they not absolutely such, but the smallest of their kind, that is, such as to which those bodies when they are resolved do return, and consequently not into Elements, but into those things of which they immediately consist. Milk turns into Butter, Whey, and Cheese. So the same heat acting upon the homogeneal meat changes it into divers humors, according as it is disposed, nor does it of any Particle form every thing. Wine I conceive is rightly held to be not a thing blended and jumbled, but a perfectly mixt Body intused. But if it be put in a Stil and stilled, little Spirit that wil burn is drawn forth, much Water remains and a little Earth; because there is more Water than either Fire or Earth in Wine; which yet would not so come to pass if out of every smallest Particle, Fire, Air, and Water might be drawn.

Into what mixt bodies are resolved.

For indeed, as hardly any mixt body is composed immediately of the Elements; so also mixt bodies are rarely resolved into the Elements. Which is apparent by the corruption and resolution of things, both violent by fire and burning, and natural. That Plants and Animals when they are dead and putrifie are not resolved quite into the Elements, that smel and stink does sufficiently evince which belongs to no Element but is proper to mixt bodies. And as of things living some have one smel, and some another: so also is it with Plants and dead Carkasses. Yea, and the pestilence hath been frequently observed to arise from the putrefying Carkasses of dead Animals. The same happens in violent Resolutions which are made by Chymical Distillations and Sublimations. *Zabarella* indeed *Lib. 2. de Mistor. Generat. & Interitu, cap. 2.* writes, That Cumbustion is the mutation of a mixt body into one Element only, namely Fire, some part of Earth excepted. Also many others do imagine, that if they see a fume or vapor ascend out of any thing, that the said thing is resolved into the Elements. But the matter goes far otherwise; for the fire retains its own, and gives to others that which is theirs. Fire is used in Chymical Distillations and Sublimations, somtimes gentler, other whiles stronger; yet neither of them resolves things into the Elements. For although fumes and vapors ascend; yet if they be received in Alembicks and Receivers, it is apparent that the resolution is made only into Atomes of a peculiar kind; and some flowers are gathered of Mercury, others of Sulphur, others of Sal Ammoniack. So in Distillations although one kind of vapor seem to arise; yet if it be collected in an Alembick, it appears to be Spirit of Wine, or Cherries, or Juniper, *Aqua fortis*, or some other Compound. Yea, although they may ascend insensibly, so as not to be discerned by the eyes, so as to pass through a thick paper four times doubled: yet are they not changed into Air, but into a spirit of its own kind. Yea, if Sulphur, or Pitch-wood, or Pitch be set on fire, they turn not into Elements, but their proper Oyls are gathered therefrom.

And from what hath been hitherto said, it is apparent that the primary efficient Cause of that mixture in Plants and Animals, yea, and al perfectly mixt bodies, as Stones, Jewels, Minerals, and Metals, to constitute their Bodies, is that same specifick form of a natural body, which draws matter fit for it self, and disposes the same after a certain manner.

Some Mistions are made by consent & dissent of Atomes.

But al other Mixtures which are not directed by a superior form, by what names soever called, proceed from the Content and Dissent of Atomes, by means of which like are moved to like and like are assimilated to like. For although this likeness and unlikeness of Bodies of a kind does not a little help towards the more convenient mixture which is made in Animals, and is governed by a more noble Form (as we see like meats are more easily digested than unlike) yet this mixture hath place chiefly in fermentations, either natural or artificial, and in the preparations of Medicaments, as also in those which are called recruitous. And this similitude of the smallest Atomes of a kind as it is the foundation of many mixtures, so is it of al Solutions. After this manner the fermentation of Wine, Beer, and al

Juyces

Juyces is made, viz. whiles such as are of the same Nature are united, and expel things different from them, and drive them out as dregs; which is chiefly effected by help of that same inbred Spirit which penetrates into al parts; which also we see betide in the fermentation or Leavening of Bread.

Whether Wines, medicaments, Treacle, Mithridate, and distilled waters, are bodies really mixed.

What we should think of white and red Wine mingled of Honey and Wine, of Medicinal Wines, Treacle, Mithridate, distilled and compounded Waters, and such like, whether they are true mixtures, or only things blended together, is a question amongst Authors. Some hold they are but things jumbled together. So *Thomas Erastus*, *Disput.* 2. *contra Paracels. page* 212. saies, white and red Wine mingled is but a jumbled thing, and adds this reason, Because our Taste tels us, that the taste of either of them stil remains, and that neither Wine hath lost its own nature, and it cannot be the redness should possess any but its own proper subject. And concerning Treacle *Zabarella* writes, *de Mist. cap.* 13. That Treacle hath no true mixture, or if it hath, that it is the mixture of the Elements, and not of the Ingredients of the Treacle. But these Opinions are founded upon a supposition not yet granted, viz. That nothing is mixed but the Elements, which we have before proved to be false. And therefore if otherwise it is sufficient to the Constitution of Natural Bodies that smallest Atomes of several kinds should meet and be united; of which because somtimes these, otherwhiles those are in greatest quantity, therefore the taste, smel, color, and other qualities somtimes of these, otherwhiles of those do abound, as otherwise in the mixture of Elements, the Qualities of the predominant Element do excel the rest: verily I shal not deny, when such bodies are first blended, they may be termed things jumbled, but when after Fermentation, or frequently repeated distillations, they are united in their smallest Particles, I see no cause why they may not be called bodies truly mixed. And if that cause were sufficient which *Erastus* brings to prove that white and red Wine blended are no truly mixt Body, most Wines should not be true mixtures; since most Wines are made of several sorts of Grapes, and therefore somtimes they taste like one sort of Wine, otherwhiles like another.

THE FOURTH DISCOURSE.

Of the Generation of Live Things.

Chap. 1. *Whether Souls are made?*

SInce Plants and Animals do not last in their Individual or particular Beeings, but some die, and others spring up in their place, and so the kinds and sorts are preserved to the end of the World, and as long as it pleases God the the Creator: it is altogether worth our Enquiry how this Generation of Living things, and the preservation of their kinds by individuals continually succeeding one another, is brought to pass; especially since renowned Men have been carefully busied, and in doubt also concerning this matter. Now al living things consist of Soul and Body. Whence they have their Body is cleer enough; but whence they have their Souls is not so evident. We are therefore now resolved to make that our Enquiry. Which whiles we do, we shal consider the matter it self, and not contend only with Authorities, nor shal we bring our selves into a Labyrinth and Maze, wherein many wander about and can never get out, whiles one while they follow Reason, another while Authority, and make it their business, alwaies to save the Authority of great Authors, and so vainly labor (oftentimes) to reconcile Truth and a Lye together.

The essential parts of living things.

And although there are divers sorts of Living things; yet since al of them have life from the Soul, we shal speak in general whence living things receive their Souls, and whence Souls have their Original.

In the first place, Some do here briefly quit themselves, and deny that forms (such as the Soul is) are made. For thus saies *Toletus*, Lib. 1. *Phys. cap. 9. qu. 19. We wholly deny with* Aristotle, *that Forms are made or produced; but Compounds are made, not out of nothing, but of matter; but the Forms are consequently made and comproduced: whence they are not created, because Creation is an action whereby a thing is first made; but the Forms are not first made. And this is the power granted to Natural Agents, that they might produce a Compound, and also mediately the Forms withal, which is not to create, nor have we any other Philosophy from* Aristotle, *and it is an excellent one, and worthy to be noted.* The same Author in the same place saies thus: *The Form is not produced by it self, but it is comproduced upon the production of the Compound, that is to say, the action is determinated primarily upon the Compound it self, and consequently, and as it were by accident upon the Form.* The Conimbricensian Collegiates in Lib. 1. *Phys. cap. 9. quæst. 12. artic. 6.* thus write: *We answer, by saying in the first place, that no Form except a Mans is properly made; because making is not incident save to a thing subsisting of it self.* And *Ruvio Rodensis*, Lib. 1. *Phys. cap. 5. in quest.* writes thus: *We deny that the form is made of the matter, or of Privation. For according to the propriety of Nature the Form is neither generated nor made, but the Compound, as* Aristotle *expressly teaches, Lib. 1. Phys. text. 64. in these words*: wherefore it is manifest from what hath been said, That whatever is made, is stil the Compound. And *Thomas Aquinas* in their Exposition. *And this Reason proves*: *The making of a thing tends to the Beeing thereof. Therefore it belongs to that only to be made, which hath being: but the Form is not; but it is only said to be the cause of being to the Compound, which is properly said to be. Therefore the form*

form is not made, but the Compound. Which if it be not made; ergo it is not made of the Matter, nor of Privation, but the Compound is said to be made of both, by means of the Form from which it hath its being, and whose Principles are Matter, Form, and Privation. Now to be drawn out of the Power of the Matter is not to be made of it self, but to go into act, as the cause of the Compounds Being, which of it self is generated and made. So far *Ruvio.*

Others contrariwise do oppose this foresaid Opinion as false and absurd. For seeing to the Constitution of every Body, Matter, and especially Form which gives the specifical being, is requisite, and dayly some Individuals perish, and others are generated; of necessity the matter and form which before were not, must be made. But according to their reason which they propound without proof (viz. That neither the Matter nor the Form is made, but the Compound) nothing should be made; since of the Matter and Form the Compound consists, and the Compound is nothing but the Matter and Form. Nor to the making of any thing is a compleat Being requisite, but any Being is sufficient; and that which now is what before it was not, is justly said to be made, whether it be an incompleat Being, or a compleat and Compound. And those are words and sounds without Sense, that Forms are not produced, but comproduced, and that they are not primarily made, but by accident as it were produced upon the production of the Compound. The Compound (truly) is primarily intended in the whol Generation, but it cannot be accomplished unless al things are made which are required to its Essence and Constitution. Yea, they themselves who deny that Forms are made, forgetting themselves they say they are made, when they teach that such things as are drawn out of the power of the Matter do depend upon the matter in their being, making, and operation. Nor do they remove this doubt; but they are forced to explain whence Souls proceed; and at last they are forced to hold, That they are drawn out of the power of the Matter.

And therefore it cannot be simply denied, That Souls after their manner (for whether it be a proper manner of speaking, when Souls are said to be made, even the most learned *Caspar Hofmannus*, in *tr. de formarum origine*, at the beginning doubts) are made. Yet if we would speak more properly, they may rather be said to be multiplied than made, according to that vulgar Saying; Every Form hath a power to multiply it self. For those things are properly said to be made which are not at al before they be made. But that is said to be multiplied which whereas before it was one in one Individual, it now becomes manifold, and many in number. Of which I shal speak in Chap. 6.

Souls are rather multiplied than made

Chap. 2. *Whether Souls come from God, or from Heaven?*

Avicenna held, That the Souls of living things did not proceed from their Parents, but from a certain Intelligence the Giver or (as *Scaliger*, *Exercit.* 97. speaks) the Disposer of Forms, which he terms *Colcodea*; and he teaches, That this Heavenly Intelligence uses the Seed as an Instrument to produce the Vegetative and Sensitive Soul, which when he hath produced in a man by help of the Seed, in process of time without the help of any Instrument the Rational Soul is brought in, and into the Body informed with a Vegetative and sensitive Soul he pours in out of himself a Rational Soul, free from the commerce of Matter. And doubtless *Avicenna* drew this Opinion from *Plato* and the Platonists. For they (as may be seen out of *Plato* in *Epimenide & Timæo*, Marsilius Ficinus *super Lib. Platonis de Sanctitate*, and *super Timæum Platonis, cap.* 37. And *Alcinous*, in *Lib. de Doctrina Platonis, cap.* 23.) do hold, That Rational Souls do come from the most good and great God, and the irrational Souls from the inferior gods, which are (according to them) either the Cœlestial Bodies, or their Spirits, and moving Intelligences. But such things as are said of those Intelligences in Natural Philosophy, since they are said without any reason, they are worthily rejected by Philosophers. And if there are any Heavenly Causes at al, which make towards the Generation of things, they are remote causes, and universal, as shal by and by be said concerning the Opinion of *Fernelius*. And if by that first Intelligence they mean the most good and great God, this Opinion is also false. For the Question is not here concerning the Creation, but the Generation of things. But God after he once ceased from Creation, does create nothing unless it be miraculously; but he hath ordained Nature which performs the Course of Generation and Corruption, and defends and observes the same. And now indeed, God concurs as the first and universal Cause in the Generation

The Souls not from God.

How God concurs with second causes to the generation of things.

neration of al things, but the things produced are the immediate effects of the second Causes: And God is said to be the Efficient Cause of al things, both because he first created them, and because he gave to the Second Causes the force and ability to produce their Effects. This indeed is true, That the second Causes cannot do any thing without the first, viz. Because from it al created Agents depend and have their Essence, and without the assistance whereof they could neither consist nor perform any operation; and unless the first Cause concur to the Act, the second cannot perform their operations. Yet the Second Causes do really act, and God acts in al, so as that they may work also; whence *Scaliger* in *Theophrast. de Caus. Plant. Lib. 5. cap. 1.* writes, That Nature is the Power of God in second Causes, to which he hath prescribed certain Rules. And if the second Causes did nothing, why should there be so various a Fabrick in things created, and why are so many Vertues and activities bestowed upon them? and why cannot lifeless things perform the same Operation as living things? And therefore since in the generation of other things we do not look simply to God, but joyn also the second Causes; why should we reject them in the Generation of living things? And if Souls should proceed from God alone and immediately, like could no waies be said to generate its like, nor could that from whence the seed of a Plant or Animal is taken be termed the Parent of the new Plant or Animal, but God. And if they should say that God uses the seed as an Instrument: yet as an Instrument, viz. a Chizel cannot be called the Efficient Cause of an Image, nor the Image be said to be the effect of the Chizel: so neither can a living Creature be said to be the Off-spring or child of the seed. In a word, if any superior Cause whatsoever, by *Plato* and the Platonists, or by *Avicenna*, shal be held the Efficient Cause of Souls, there wil be after this reckoning no univocal Generation; whereas nevertheless most certain it is, nor needs it any proof, That like begets its like, an Oak tree an Oak, a Horse an Horse, a Man a Man.

And what the Platonists say touching the inferior gods, if they are to be understood as the words intimate, any one may easily see that they are not only said without al reason, but void of Truth.

Whether Souls come from Heaven?

The Opinion of Fernelius.

Fernelius differs not much from them, who *Lib. 1. de abdit. rerum causis*, in many places eagerly defends that every Soul comes from the Heaven, & that the Heaven sends every Soul into matter prepared and fitted. For thus (in chap. 5. towards the end) he writes; *In the Generation of living Creatures the seed conceived is by the Vertue and benign warmth of the Womb stirred up to action, not that it might raise up out of it self a Soul, or the form of an Animal, but only that the power and faculty thereof being first stirred up and provoked, and afterwards augmented, might furnish its subject matter with all kind of preparation, that the substantial form may at last be received thereinto from without.* He propounds the same Opinion at large, chap. 7. and afterwards, chap. 10. he ads: *The Heaven* (saies he) *without any Seed brings forth many Plants and Animals; but Seed breeds nothing without the Heaven. The Seed does only neatly and decently prepare the Matter, the Heaven sends the form into it when it is prepared, and the chief perfection, and stirs up life in all.* And at last he concludes: *Whatsoever things God made of old in Heaven or in Earth, he alone defends and governs them all, the Heavenly things indeed by himself immediately; but living things and Plants, and other mortal Creatures, by help and assistance of the Heavens on whom he hath imposed the Procreative and Conservative Laws of Nature. And therefore the only form of Heaven does potentially contain the forms of Live Creatures, Plants, Stones, Metals, all that ever have been or can be; and it being big as it were with innumerable forms, engenders and pours all things out of it self: the only power and faculty thereof contains in it all the faculties of mortal things which ever have been, or shall be hereafter. And these Vertues the Soul of the World shed into the whol Universe from Heaven bestows upon all things, as also their form, and native, and vital heat, fit to generate and to conserve them. It contains all things, and cherishes al things with heat and life, so that there is not any where any thing not replenished with the fulness hereof. By the vertue and means hereof both all lifeless things are by themselves, and al animated things have such a Soul as belongs to their kind, some a nourishing, others a sensitive, and others a rational. So she accommodates her self to things, so subservient she is to the Natures of each one, that she gives as much as the Nature and condition of every one desires, and as much as the preparation it self of the subject can bear. The Sun though exceeding far off; yet so bestows his light upon the bodies opposite unto him, that they are bright and shine with splendor: but Water after one manner, a Stone after another manner, Wood after another manner, Silver after another manner, Even so, much after the same manner, that Vertue also which comes down from Heaven is vital, yet so that upon some things*

it bestows only a Beeing, to others also a Soul, and that either nourishing, sensitive, or rational: for it is not received after one manner of all. But of this also I would last y admonish the Reader, That the said Cœlestial Vertue it self is not alwaies alike, nor does bear it self alwaies alike to sublunary things, but differently at different times, according to the manifold posture of the Stars, whose commixtion and complexion does for the most part vary, although the Substance of the Soul of the World (or carrying spirit) is unchangeably one. It cannot therefore come to pass (as one man saies) that the Soul of the World so imparts life and state to all things as that it needs not the least help of the Stars. If this were so, why I pray you should it not alwaies generate like things, and after the same manner, seeing it is alwaies alike present to things. So far *Fernelius*.

Now the chief Arguments whereby he endeavors to prove his Opinion are these: The first is, That of putrefying matter many Animals are bred, which since they come of no Seed, and from no Parent, he concludes their Soul comes from Heaven; and therefore since those more ignoble Animals receive their Souls from Heaven, he thinks the more nobler Creatures, as a Man and a Lyon, should much rather receive their Souls from Heaven. Secondly, seeing *Aristotle* writ, That a Man and the Sun beget a Man, he conceives they do not both concur after the same manner to the generation of a Man, nor that the same thing is effected by both of them; but since two things are required, the Matter and the Form, that by Man as the more imperfect nature the Matter is prepared, and the Soul sent in from Heaven. Thirdly, He disputes at large against the Eduction of Forms out of the power of the matter. Fourthly, He produces many things touching the nobility of the Heaven, and its action upon these lower bodies. Finally, Since the Soul is united to the Body by help of an Heavenly kind of heat and spirit, he holds the Soul it self must much rather be of a Cœlestial Original.

Fernelius his Opinion of the Original of Souls confuted.

But in good deed this Opinion is far from the truth. For seeing that living things which are generated are of the same sort with those by which they are generated, how can this be true if the Generator do only dispose the matter to receive the Form, and do not impart the Form it self? and al living things should rather be termed the Off-spring of Heaven, than of those things by which they are geuerated. And though there be a content of the upper and lower bodies, and the Heaven as an universal Cause does further the Original of things; yet it does not follow, That the Heaven gives Forms to so many several sorts of things. And what need is there to derive the Souls of things from Heaven, since God the Creator in the first Creation gave to al living things the power to multiply themselves.

His Arguments.

Nor are those Reasons which moved him to maintain this Opinion of any strength. For in the first place, That living things Generated of themselves have their cause here below shal be shewed hereafter. Nor if there be any thing noble here below must that needs be deduced from Heaven, but living things themselves have their degree of dignity; and man the most noble of al is nobler than the Heaven. Secondly, though *Aristotle* wrote that the Sun and Man generates a Man; yet is not that to be otherwise understood than that the Heaven as a remote and general Cause, and Man as the immediate Cause generates a Man. Nor (as was said) is Man more ignoble than the Heaven, so that he only should prepare the Matter, and the Heaven give the Form. Thirdly, He does rightly oppose the Eduction of Forms out of Matter, and we shal do the same hereafter: but it does not follow, If Forms are not educed out of the Matter, that therefore they are procreated by the Heavens. For we shal hereafter demonstrate another manner of their Original. And as in the fourth place we grant the Nobility of the Heaven, and its action upon these lower bodies; yet it no waies follows therefrom that it is the Author of al Forms. Finally, although it were granted that the innate heat and spirit, which the forms of living things use as their immediate Instrument, and which may therefore be called the band of the Soul and Body, may after a sort be termed Cœlestial; yet that only does thence follow, that the Souls themselves are more noble than that spirit and inbred heat, but not that they proceed from Heaven. In a word, as *Thomas Erastus, de Occult. med. propriet. Lib.* 1. *cap.* 17. does wel write: They that dare affirm the Forms of the sorts of things are infused by the Stars wil be laught at by Philosophers; and by Christians also rightly judged execrable. The Forms have received their Original not from Heaven, but from the Creator, if they wil rather beleeve the History of the Creation than lying Fables. God commanded that every Species or sort of things should propagate it self by multiplication of Individuals endued with the same Faculties; he did not command the Stars either to imprint their forms or vertues on the things created.

Thus have we shewed how some without Reason have endeavored to draw the Original of the Forms of Living things from the Heavens.

CHAP.

Chap. 3. *Some other Opinions of the Original of Souls reckoned up, and a vulgar Error taxed.*

A twofold Generation of Living things.

SInce therefore the Soul proceeds not from the Heaven and superior Causes, many grant that like begets its like. Which yet most do understand only of univocal Generation. For they hold a twofold Generation; one univocal, whereby like begets its like; the other Equivocal, where the Ingenderer is of a different nature from the thing ingendred; which they say happens in such things as are bred of themselves, and without Seed. But whether there be any such Equivocal Generation, and what the Nature of the Spontaneous Original of living things is, we shal shew hereafter in its place. It suffices in this place that in Univocal Generation so called, it is granted by most, and by al that do not draw the forms from Heaven or a superior Cause, that like engenders its like. Yet in good deed, although al agree herein; yet they differ much as touching the manner, and there are many and divers Opinions of Authors hereabouts, al which may nevertheless be (I conceive) reduced to four Tribes. For first some hold the Seed to be inanimate; who are again divided into two companies; whiles some hold the Seed communicated by the Generator to be only instead of matter, out of the aptitude whereof the Soul is educed by an external Agent: some say there is a formative Vertue communicated to the Seed by the Generator, and they hold that it is the shaper of the Body of the living thing; or they conceive the Generator uses the Seed as an Instrument to beget its like. But others hold that the Seed is animated; yet they are of two opinions; for some hold there is in al Seed (even that of a Man) its proper Soul; but some conceive the Soul of Man (by reason of a singular prerogative) is to be exempted, and that it comes into the Body after it is formed from without; though they themselves differ about the time when the Soul comes: Touching al which Opinions we are now to speak severally.

Four Opinions concerning the Generation of Living things.

The Original of the soul in general is to be enquired into.

Howbeit the Reader must first be warned of a vulgar Error. Since all living things are what they are chiefly by their Souls, and thereby they differ from lifeless things; therefore with good reason our enquiry touching the Original of Souls must be here so ordered that it may concern al living things in general. In which thing nevertheless I see many offend, who deliver what should be said of the original of the Soul, and formation of the Body of a living thing in general, concerning a Man only, and so they offend against the Law of Demonstration, endeavoring to demonstrate the affections belonging to the whol kind of one sort only. I conceive it therefore more convenient to propound in general whatsoever may be said of the Original of living things, and of Souls in general; and afterwards to apply them particularly to Plants, Animals, and Man-kind; and what these sorts of living Creatures have peculiar, to set that down by it self.

Chap. 4. *Whether Souls are drawn out of the aptitude of the Matter.*

Whether Souls are drawn out of the aptitude of the matter

IN the first place therefore, amongst those who hold the seed to be inanimate, it is a common opinion, that all forms and consequently all Souls, except the rational soul of a man are drawn out of the aptitude of the matter. But who was the first Author of this Opinion, is not so certain. Most do indeed father it upon *Aristotle*; but I doubt whether it can be demonstrated from his works. Some, and amongst them *Franciscus Bonamicus*, do attribute to *Averroes* this Opinion; and some such words are found in his Books; but it many times happens, that Expositors patch many things of their own upon Authors. But whether he held what is vulgarly taught is a great question. For it is apparent, as from other places, so from 7. *Metaphys. text.* 31. That he held the Cause of the Generation of living things, or rather of the formation of a living Body, to be the form lurking in the Seed. For seeing there *Aristotle* compares Artificial things with Natural, and touching the Seed which is the Efficient, he saies, It makes, *Averrhoes* adds; the Seed generates by a power it hath like to an Artificer; because the form of the thing generated is potentially in the Seed, and that of which the Seed is agrees in name and nature with that which is any waies made of the Seed. And a little after: In the matter of things generated there is an aptitude that out of it may be bred a like thing by the power which is in the Seed.

Who was the Author of the Opinion of drawing of forms out of the aptitude of the matter.

But

But moſt of the Schoolmen and their followers have fiercely maintained this Opinion of the eduction of Souls out of the aptitude of the matter, and have handed it over to poſterity without any cleer ſence, which a mind deſirous of truth might conceive; ſo that moſt of them ſeem rather to have tranſcribed the words of their Maſters, than to have underſtood the thing it ſelf. And how indeed could they underſtand where there was nothing to be underſtood?

But whoever was the Author of this Opinion, and whatever Patrons it hath; it muſt by al means be weighed and conſidered, ſince many contend for it as if their life lay at the ſtake, and uſe it as an infallible Principle to decide many Controverſies. Now two things theſe Authors do: Firſt, they ſet down the reaſons moving them thus to think, or rather they oppoſe the Opinions of others: and in the next place they endeavor to explain and declare their ſaid Opinion.

And in the firſt place (truly) as appears out of *Fonſeca*, *Comment. in* 5. *Met. cap.* 2. *quæſt.* 4. Suarez, 12. *Metaphyſ. diſput. Sect.* 1, 2. Bonamicus, Ruvius, *in* 1. *Phyſ. tract.* 2. *quæſt.* 1. and others, they bring hardly any evident reaſons for their own Opinion, but only endeavor to bring thoſe that think otherwiſe into ſome abſurdity; which is a very ſuſpicious way of dealing. For it is the part of a good and Ingenious Diſputer firſt to prove his own Opinion with firm Reaſons, afterwards to oppoſe the contrary. And nothing can be ſaid ſo true and manifeſt which by contentious wits may not be called in queſtion. I count it not worth the while to tranſcribe the places of Authors entire; ſeeing they are in the hands of al, and moſt of them bring nothing new, but repeat the ſame thing over and over again. But if any reaſons may be gathered out of them, they are theſe:

Reaſons for the Eduction of forms out of the aptitude of the matter.

In the firſt place therefore, They would prove that Forms are drawn out of the power of the Matter, becauſe they depend upon the Matter in their making, their being, and operation. But this is to beg the Queſtion, and there is no connexion of the major. For we grant indeed that thoſe inſeparable Forms cannot be made (or rather propagated) without the matter, and that they are, and work in, and with the matter: but it does not hence follow, that the Form is drawn out of the power of the Matter, and depends in its eſſence upon the matter, which is meerly paſſive. But the Queſtion ſtil remains, Whence thoſe Forms which can neither be made, nor be, nor operate without the matter, or out of the matter, have their Original.

Secondly, Unleſs we hold that Forms are drawn out of the aptitude of the matter, they conceive al Generation is taken away. Which argument whether it be a direct proof, or a deduction to an abſurdity, I leave to others to judg. For either (ſay they) the Forms are ſomthing before Generation, or they are nothing. If they were before Generation, there can be no Generation; if they are nothing there wil be a Creation, and ſo Generation is again taken away. But this Dilemma is of no weight, nor is there any ſtrength in either of its horns. For ſince they were al for the moſt part Divines who thus wrote, they ought to have conſidered what that text of Scripture imports, *Encreaſe and multiply*; yea, and how that axiome of Philoſophers is to be underſtood, That every Form can multiply it ſelf. For if they had underſtood that Souls can multiply themſelves, they had underſtood withal that when any particular thing generates, a ſoul is not created anew, but multiplied; and that the Souls of the firſt Individuals of every ſort, created by God at the beginning of the World, did and do ſuffice to propagate al the Souls of al the Individuals that ever have been, or ever ſhal be; and they had underſtood withal that when Souls which were before are multiplied, generation is not taken away, but rather eſtabliſhed. For though the Soul were before, and only one in number; yet when it multiplies it ſelf, and diffuſes it ſelf into more Individuals, Generation is rightly ſaid to be made. Where notwithſtanding we muſt preſently obſerve when Generation is truly made. They indeed hold, when of a grain of Wheat there ſprings up a Wheat ſtalk and ear, or when a Chick comes out of an Eg, then generation is made. And it may indeed be granted, that after a ſort Generation is then made. But if we would ſpeak properly, ſince Generation is (as *Ariſtotle* teaches, *de reſpiratione, cap.* 18.) *The firſt communication of the nutritive Soul together with the inbred Heat*; that communication is then performed when Seed is bred and ſeparated from the Generator: and then Plants, then Animals breed, when they communicate their Soul together with their native heat unto the Seed, and caſt the ſame forth of themſelves, but not when a Plant or Animal is produced of the Seed. Which is hereby apparent, in that when Plants ſpring up out of the ſeed the Plant that bred the ſeed may be deſtroyed, and when the Chick is hatched out of the Egg, the Cock and Hen whence that Egg came may be both dead, and ſo can neither communicate the Native Heat, nor the Soul. And therefore *Julius Cæſar Scaliger*, *Exercit.* 6. *Sect.* 10.

How living things are generated.

when generation of living things is truly made

The Tree ingenders (saies he) when it produces Seed; but a Tree is not generated when it shoots up from the Seed; but then that which was generated and imperfect is perfected. So a Dog does not engender when the Whelps are brought forth, but when the Seed is bred.

whether that Opinion of the eduction of forms out of the power of matter can be explained.

But when they that hold Forms are drawn out of the power or aptitude of the Matter would explain their Opinion, they variously and miserably vex themselves and trouble their Brains to no purpose; as is usual when there is nothing at the bottom; and while they endeavor to explain the matter, they rather obscure and perplex the same, as may be seen out of the Authors fore-alleadged, also from *Tolet.* 1. *Physic. cap.* 9. *qu.* 19. and 1. *de generat. & corrupt. cap.* 3. *qu.* 2. Benedictus Pererius, *Lib.* 5. *Phys. cap.* 22. and others, whole words I think not fit to transcribe; and at last when they have turned this way and that way with much anxiety, at last they conclude with those words of *Aquinas*, *Part.* 1. *Quest.* 90. *artic.* 2. for the Form to be drawn out of the aptitude of the matter is nothing else but for a thing to become actually what it was before potentially. But whether this can satisfie a mind that hungers after Truth, I leave to the Reader to judg. Whence *Tolet.* 1. *de Gener. & Corrupt. cap* 3. *quest.* 2. *I confess* (saies he) *this is a wonderful Vertue which partakes of a creating power; but it is not a creating power because it alwaies works upon subjects. The Vertue also of the matter is wonderful, out of the aptitude whereof are brought things which are not actually.* Where rather he should have admired at their stubborn headiness, who would needs have it to be brought out of the matter which is impossible, and is neither in the power of the Matter nor of the Agent, than at the wonderful power of the Matter which is none at al. And *Benedictus Pererius*, *Lib.* 14. *cap.* 9. at the end, where he treats of the Original of Forms, and endeavors to answer some doubts, at last he concludes: *Whether these Answers are true, and whether they quite take away the difficulties proposed I leave to the judgment and consideration of learned men: they do not (truly) quite take away my scruple, nor perfectly satisfie my mind. For they involve certain things which seem either absolutely false, or more doubtful than that whereof we now doubt; such as is that there is an* ultimum *or last of Quality, which may be brought in in an instant.* And indeed they can no waies answer the doubts that are brought against their Opinion. For if you ask them, what it is to be brought out of the power of the matter? or what that power is? they answer, That it is the disposition of the matter to a certain form, that when the ordinary power of the Agent or efficient is added, a form grows and results therefrom. But when they themselves grant, that this disposition belongs to the second matter (not to the first, for that is indifferent to receive al forms, nor more determined to one than another. And if the first matter should contain al forms in its bosom, and the forms did owe their Original to the first matter, that matter were a more noble principle than the form) since one disposition is required to the form of an Oak, another to the form of a Chick, another to draw out the form of a Horse; and the same Expounders of *Aristotle* determine, that the Matter wherein such specifick forms hang, is the Elements variously mixed and disposed: it is demanded (since they hold the form is made actually, which was there before potentially) Whether it be made of nothing? or whether that same disposition and Qualities of the Matter, which are nothing but a certain temper of a mixed body, or the very form it self of the mixt Body or Elements, is changed into the form of an Oak, an Hen, or an Horse? None of which can be said without absurdity; since neither an accident can be changed into a substance, nor one form into another; nor can the forms of living things be compounded of the Elements. And which way soever that disposition to the form can be explained (since it is made successively by parts, and the last degree is of the same kind and perfection with the former) it cannot make up the act of a thing, nor give Essence to a Substance.

Absurdities which follow the Opinion of drawing the Forms out of the aptitude of the matter

Moreover, Neither can they produce any thing of certainty concerning the immediate and principal Efficient of that Form which they say is drawn out of the power of the matter. The matter it self being a passive principle cannot be the Efficient cause; nor the Sun, or other Stars (since they are only remote and specifical, not universal causes, as was said before, Chap. 2.) Nor the external Heat of the Air, Womb, Hen-sitting, Furnace, or any external thing whatsoever. For so a substance should be produced by an accident. Moreover, there could not be assigned a specifical Cause of a special Effect; but the same special Effect should be produced by divers Causes: as we see Plants sprout out of the Seed both by the heat of the Sun and of a Stove, and the Chickens of one Bird hatched by another Bird not of the same, but a different kind; yea, and the seeds of Silkworms are hatched in the bosom of a Damsel, as *Vida* relates in his *Poeme of the Silkworm*. Moreover by the action of one

one Agent moſt different Forms ſhould be produced. For ſince in the ſame Garden moſt different Plants do grow, they cannot al proceed from the ſame Agent, viz. The external Heat. Moreover, according to this Opinion the things generated ſhould not have their form from the Generator, but only a diſpoſition to the form, which afterwards of its own accord upon the action of an external Agent (as Heat for example) ſhould ſpring out of the power of the matter, the Agent communicating nothing thereunto. And ſo according to this Opinion it cannot be ſaid that a living thing begets its like, nor that every form does multiply it ſelf: which yet al ſound Philoſophers do grant. For if the Generator ſhould tranſfer nothing of its own Eſſence into the thing Generated, but ſhould only determine the matter to ſuch a like form, and afterward the Efficient (which is not of the ſame kind) ſhould make it actually to break forth; how I pray you can the form be ſaid to multiply it ſelf? Verily, if ſome Plant in the *Indies* when it produces Seed gives nothing but the matter with a determinate aptitude to receive a like form, out of which after a yeer, two, or three, the Plant it ſelf being now burnt or putrefied, the form ſhould break out by vertue of heat, not only of the Sun, but of the fire in a ſtove, as the Agent: that Plant cannot be ſaid to have bred its like, nor that form to have multiplied it ſelf. Nor is it enough to cauſe an univocal Generation, and the true production of a like Eſſence, to afford a matter with ſome proclivity and propenſion to receive the form. And after this reckoning the Agent heat (and that an accident) ſhould confer more towards the Generation than the Generator it ſelf, ſince it makes the form actually to ariſe which the Generator cauſed to be there only potentially. And thus it remains yet unexplained, whence the ſubſtantial and ſpecifick form of a thing, or that more excellent, more divine and chief part of a thing hath its Original. Mean while we grant that the diſpoſition of the matter is neceſſary to the Generation of living things, ſince every matter is not fit to receive every form, but a determinate matter a determinate form: but not that the form or ſoul ſhould be made out of it; but that it may be propagated thereinto, and afterwards dwel therein, as ſhal be ſaid hereafter.

The Opinion of Fortunius Licetus concerning the Eduction of Forms out of the aptitude of the Matter.

Fortunius Licetus, *de ſpont. vivent. ortu, Lib.* 1. *cap.* 83. endeavors to explain the Eduction of forms out of the power of the matter, after this manner: We ſay (quoth he) that the Eduction of the form out of the boſom of the matter is not the drawing out of that which lies hid into the open view, but the converſion of aptitude into act. For the form which is produced by the Agent only by the tranſmutation of the matter did potentially pre-exiſt therein, out of which it is brought into act. Moreover, we deny that the Form is made of nothing, and abſolutely created, if it be granted that it is not made of the matter as a principle, nor out of that in which it did actually pre-exiſt. For in the firſt place, whatſoever things are truly created they are made ſimply of nothing, and of no ſubject at al; but al forms under the Soul of Man are made of nothing of their own, but not abſolutely of nothing, as thoſe things which are created; ſince forms are made by the agent, by a tranſmutation made in ſuch a determinate ſubject, on which therefore the forms depend in their Being, and by which added to their Eſſence they are defined according to *Ariſtotle*. Again, if it were not ſo accidents alſo ſhould be made of nothing, and moſt properly created: for no heat did pre-exiſt in the water which is made hot. But verily forms are not truly created, nor are they out of nothing of their own, but properly out of the boſom of the Matter they are drawn, and out of the aptitude thereof, becauſe they are truly generated of ſome rudiment of themſelves pre-exiſting in the matter, which rudiment of the form is perfected by the action of the Agent, and turns to a perfect Form. So far *Licetus*. But this is a vain put-off. For let *Licetus* teach us what that Rudiment of a Form is. Whether the ſubſtance of the matter it ſelf, or ſome accident thereof. If the former, (to which he ſeems to incline when he writes that the forms are made by the agent, by a tranſmutation made in ſuch a ſubject ſo determined) then the matter ſhould be changed into Form: if the latter, an accident muſt be changed into a ſubſtance. Let him ſhew us alſo, that there is any rudiment and beginning of a form, ſince forms are indiviſible, and have their Eſſence like numbers; and therefore where they are they are totally, or not at al. Nor does the ſame *Fortunius Licetus* explain this matter more happily, *Lib.* 4. *de ſpont. vivent. ortu, cap.* 15. where he defines the Beginning of Forms, and holds that in the matter there is pre-exiſting a rudiment of the future form, that the generical nature of that form remains under the oppoſite privation, to which the efficient cauſe joyning the ſpecifical difference of the form is ſaid both to conſtitute the form, and to further the Generation, and at once to generate a ſubſtance compounded of matter and form. But that ſame pre-conceived Opinion touching the eduction of forms out of the power of the matter ſeduced that man, otherwiſe a moſt diligent ſearcher into Nature. For no form is capable of more or leſs, but conſiſts in an indi-

visible point, nor can it be remitted, since remission is made by mixture of a contrary, nor is it possible that the form should first have a generical Nature, and receive the specifical difference from the Efficient. And whereas *Licetus* denies those axiomes owned byal Philosophers, and saies they hold true only in compound substances, but not in simple; this he does without Reason. For since compound substances become such by reason of the simple of which they consist, if the simple substances, matter, and form, may be remitted, also the compound might be remitted; and since the form gives being to the thing by reason of the form the compound also should be more or less such. Nor does *Licetus* agree with himself in this point, since in the same Book, chap. 2. he writes, That those things which are said to breed of themselves are not made by an external Agent, but by an Agent which lies hid in the matter of the thing to be made, which does not generate a new form different from it self, but exhibits it self thereto for a new form, that is to say, communicates it self. Nor is there in the Soul (which is a most simple Essence) any composition of sundry Essential parts, and in such a manner, that like a Genus it might be present without a specifical difference. The Soul is one most simple Essence, only furnished with sundry faculties. Nor can he shew how that remission is made. For whereas *Licetus* saies, that only an accidental remission or abatement is made by the mixture of a contrary, but not an essential, such as he holds to be in forms, is asserted without any reason; and it lies him in hand to prove, That (as he feigns) an essential remission may be made without admixture of a contrary. And which way soever he turns himself he fals into absurdities, and contradicts himself. For when he saies that that same rudiment of a form is no true form, but the generical Nature thereof, and that the kinds have an Essence really distinct from their sorts, he confounds Logical Conceptions with the Nature it self of things, or the Logical kind with the Natural. For the Logical kind is in the mind, and is by the mind abstracted from the sorts; but the Physical Genus signifies a common nature, which consists in the things themselves out of the Mind. And the Logical kind indeed may by the mind be separated from the sorts; but the Physical kind does not exist in Nature, save in its sorts, nor does the Animal exist any where save in a Man, a Lyon, a Horse, &c. And therefore it is a vain figment to say that the Generical Nature is the Rudiment of the Form, and as it were half the Form. And from this very Opinion it would follow, that like does not engender its like. For since the specifical Form gives to every thing its Nature, but not the Generical; if the Generator should only afford the matter wherein the Generical form is, or a rudiment of the Form, or an half form, as *Licetus* speaks; but the external agent as Heat should introduce the specifick difference; not the Generator which might die in the mean time before the external agent come should be the Parent and Author of the thing generated, but the external Agent; and that not univocal, but equivocal. Also I wonder a man so exceeding learned should defend this Doctrine of the Eduction of Forms, since he hath no need thereof to explain his Opinion, as holding in 1. *de sponte vivent. ortu, cap.* 125. That the seed is animated, and *Lib.* 4. *cap.* 32. that it is an imperfect Animal: and he holds that such things as are said to be generated of their own accord do not proceed from an external Agent, but from an Agent that lies hid within the matter, as was lately said.

The difference of a Logical & a Natural kind.

But which way soever they turn themselves, the matter comes to the same pass, that they are fain to confess, that besides the disposition of the matter there is somwhat formal in the Seed, the cause of action, and that besides the disposition of the matter there needs somwhat else by which the thing may be brought into its perfect act. And that power of which they speak they are forced at last to explain to be meant not of a passive power, but an active, which makes that that which is in the first act come to be in the second act, or in an act simply; so that that Soul which was destitute of Instruments to operate by is now furnished therewith, so that it is able to operate. Which very thing also *Aristotle* taught; when in 7. *Metaphys. cap.* 9. *tit.* 31. he writes: *The Seed hath the Form potentially in it self, which after a sort hath the same name with that from whence it came.* And 2. *de Generat. cap.* 1. *It is all one whether you name the Seed, or that from whence it came.* For the Sum of the business is, That that Power which *Aristotle* speaks of is formal, as later Writers phraze it, and differs not from the first act.

Whether the Eduction of the Form out of the aptitude of the Matter be founded on the holy Scriptures

A certain late Writer (whose Understanding is capable of nothing but what is Elementary) when he saw he could not defend the Eduction of Forms out of the power of the Matter by any Philosophical reason, at last he flies to the Authority of the Holy Scriptures. But he endeavors to introduce his own mind and pre-conceived Opinion into the holy Scriptures, whiles he holds, that *Moses, Gen.* 1. when he brings in *God* saying; *Let the Earth bring forth, let the Water bring forth the living Creature,* does assert that the Souls of Plants and

and Beasts were then by God produced, and do at this day arise from the Elementary matter. And thus therefore he explains it, that the specifical Forms are not made of the Elements, inasmuch as they are the matter of the mixtion, and the convenient subjects of Forms; or that they are not made by mixture and composition of the Elements, but that the Elements concur to the generation of corruptible things as they contain an universal matter so affected, under the matters of the Elements, that out of the aptitude thereof as out of a rich and unexhaustible Treasure might be drawn and propagated to the end of the World the sorts of all things, such and so many as the most good and great God would have to exist for the accomplishment and ornament of this lower World. For since the Elements contain no matter but the first, he must needs by that universal matter understand the first matter. But who I pray you, either Philosopher or Divine, did ever so teach concerning the first Matter, especially being considered without the Forms of the Elements? Did *Aristotle* (whose Opinion he conceives this of the Eduction of Forms to be) know any thing of that Divine Benediction given at the first Creation? And where do we read (I pray you) in the Scriptures that God so blessed that Universal Matter? This indeed we read in the first of *Genesis*, That God once commanded that the Earth and Waters should bring forth Animals created by him; and when they being created by God were come out of the Earth and Water like a Child out of the Womb, as *Franciscus Junius* speaks in his Explication, we do not read that God again commanded that the Earth and Water should produce Plants and Animals, and that he blessed them to that intent; but thus we read, That the Earth brought forth the green Herb bearing Seed, and the Tree bearing Fruit, and each thing having seed according to its kind; and that God blessed the Fishes and Birds being created, saying; Encrease and multiply, and fil the Waters of the Sea, and let Birds multiply upon the Earth.

Chap. 5. *Of the Formative Principle, and the separated Instrument.*

WHen other more solid Peripateticks saw these difficulties and encombrances of this Opinion, they held that the Soul indeed it self did proceed from the Generator, but not immediately. And therefore they denied that the Soul was in the Seed; yet they taught that there was a vertue therein communicated from the Generator, from whence came both the forming of the Body and the Soul of the thing generated. Of this Opinion was *Albertus Magnus*, who taught that the Generator does indeed communicate Seed, but not the Soul with the Seed, but that it only gives a vertue to the seed, by means of which (though the Generator be dead) the Seed gives a Soul to the thing generated, so that the seed which hath not the Soul in it does yet generate a living and animated thing, not of it self, but in the vertue of the Generator. For as we see in the motion of things hurled, that they are moved not by themselves, but by the force imprinted by the Thrower, although the Thrower and thing thrown are no longer together; and by the Hammer an artificial thing is made, not by its own faculty, but that of him that works with it: so by the Soul-less Seed a thing with a Soul is generated by a vertue imprinted therein by the Generator.

The Opinion of Albertus Magnus concerning the formative Faculty.

That most learned Philosopher *Jacobus Schegkius* seems to be almost of the same Opinion, who in *Lib.* 1. *de Plast. sem. facultat.* attributes a Formative Principle to the Seed, and teaches, That he thereby understands a substantial Form, which could be perceived by no sense, but by the mind and understanding. Howbeit, he holds that the Seed and this substantial Form are not principal but instrumental Agents, and form the animated Bodies like the Hand of an Artificer. He saies, That it is a substantial Act, separable from the substance of the first Act, which hath for its proper subject the Spermatical Humor. And again, that the Seed is an Instrumental Cause, and a certain efficient Principle, but not an efficient Material, making or generating the animated Body, and not being it self animated, but a Medium interposed betwixt that which is animated and that which is to be animated, without the information of any matter able to effect as a certain second act or energie. But unless the Opinion of *Schegkius* be so explained, that this Formative Principle is the Soul it self by which the Seed is animated, and the Seed of such or such a Creature; and that the Formative Power is a proper adjunct of the Soul, which it hath when it is in the Seed, and exercises the same when an Animal is generated; but inasmuch as there is not in the Seed actually an Organical Body which the Soul may inform, in that respect the Form may be said to be absent;

The Opinion of Jacobus Schegkius.

sent: then it cannot be admitted. For to hold a Formative Principle which is not the Soul, is rashly to multiply things more than needs. For since al the proprieties and operations of the Soul are found in, and attributed to this Formative Principle, why should it not be called the Soul? And seeing the Soul in the Seed is sufficient to perform al these operations which are attributed to the formative Principle, why should we hold that to be any other than the Soul? And *Aristotle* himself *de generat. Animal. cap.* 1. names this Principle a part of the Animal, which is forthwith in the Seed. And therefore we need not hold a Formative Principle as it were a second act of another first act, and the Vicar as it were of the Generator in the Seed, which when the motion of Generation is ceased, it self ceases. *For to hold that that which made either all or some parts of the Body is perished, is an absurd thing.*

The Opinion of Sanctacruz concerning the Instrumenium sedaratum.

The same Opinion (in a manner) *Antonius Ponce Sanctacruz*, the King of *Spain*'s Physitian, holds, *in opere supra primam* 1. *Canon. Avicennæ, & de Hippoc. Philosophia*, as he is cited by *Fienus* in his Apology. For he holds the Seed to be only an Instrument. But when he easily perceived many absurdities would follow if the Seed should be counted simply as an Instrument, he distinguishes betwixt an Instrument conjoyned and separate. And he conceives that the necessity of this distinction is taken from the diversity of the perfection of Agents, and the Nature of the Order of things. For some operate with a Medium and without a Medium as living things; others of an inferior Rank have not so great perfection, and they work by themselves. He tels us therefore that separate Instruments do work by a permanent Vertue which they have received from the Agent; but the conjoyned Instruments do successively receive the Vertue of the Agent, and therefore operate with dependance upon the first principal Agent. He explains the Nature of a separate Instrument by an Example political. For a King or some Potentate operates in far distant places as if he were present, by power derived from himself, which he confers upon the Laws and Judges: but private men that live only for themselves must operate by themselves. He brings afterward another example whereby he would prove his Opinion, viz. Of Watches, Clocks, and Engines wherein many Wheels are orderly moved in the absence of the Workman, yet by a vertue imprinted upon them by the first direction of the Artist. The Nature of conjoyned Instruments he explains by the similitude of a Saw, which lying stil hath such a disposition that it may receive motion in order to cutting; yet is it not an acting Instrument til it receive guidance to motion and cutting from the Sawyer. That there is a separate Instrument he also proves by the motion of hurling. For a stone hurled wil fly, though the thrower should presently fal down dead. And so he holds it is in the matter of Seed, how that Animals Generate their Seed being cast out of them, a derivative vertue continually remaining therein, that it can work, and does actually work without any actual Influx from the Generator.

This Opinion refuted.

But this Opinion however explained and palliated is false and far from truth. For *Aristotle* himself, 7. *Metaphys. c.* 9. *t.* 31. reckons the Seed amongst univocal Agents. But al univocal Agents are not instrumental but principal Causes. Again, al Instruments properly so called are joyned with the principal Agent, and as *Scheghius* himself speaks, an Instrument of it self hath no Efficacy, but only by the Use of the Principal Cause.

There is no separate Instrument which acts by it self.

And those things which are brought by *Antonius Ponce* concerning a separate Instrument (unless rightly explained) are false and feigned without reason, and therefore are not to be accounted a Metaphysical Principle, as he gives them out to be. Indeed the Seed might be called a separate Instrument, viz. Inasmuch as the Seed is not necessarily joyned with the Generator, but is subordinate thereunto, and hath received from the Generator the same power, yea, and the same Soul which the Generator it self hath. But while he denies the Soul to be in the Seed, he labors in vain when he cals the Seed a separate Instrument. For although while an Instrument is not imployed it may be really separated from the principal Agent, as a Pencil from a Painter, an Ax from a Carpenter, a Pen from a Writer: yet no Instrument can be named which in the action it self operates by a power within it self (for so it should be a principal Agent, not an Instrumental) but every Instrument in its operation hath no power of it self, but it depends upon, and is directed in its action by the Principal Agent, and when it is separated it can no longer work by it self.

The first & second Act of an Instrument

We must therefore distinguish betwixt the first and second act of an Instrument. That any thing may be an Instrument in the first act, it is sufficient that it be shaped and fitted as an Instrument for some particular action. An Iron Hammer in regard of its hardness, heaviness, and shape, is an Instrument fit to beat Gold and other Metals, and to figure and form them into some certain shape; but this is only in the first act. For an Hammer thus shaped wil

wil never of it self beat out any metal, but the presence and motion of the Artificer is necessary to dilate the same, and then the Hammer is an Instrument *actu secundo*, by the second act. So native heat is an Instrument whereby Nature digests Chyle, and forms Blood, Flesh, and Bones. But the heat cannot perform this, unless the soul which is the principal Instrument concur. And it is the nature of an Instrument to act above its own abilities, and to produce an effect more noble than it self, viz. inasmuch as it is directed and moved by the principal Cause: which while it so directs and moves does not imprint any virtue upon the Instrument, by which it may perform that Action which belongs to the principal Agent. For neither does the Artist necessarily make his Instruments, but he receives them made to his hand, either by Nature or Art, and he makes use of them being by Nature or Art fitted to his turn, as may be seen in the Saw used by the Joyner, which he had of the Smith, and in the Cole or Chalk which the Painter uses. And therefore that political example of a King working a great way off by Laws and Judges, as a moral Instance, does not square with things natural. And the subordinate Judges are rather Ministers than Instruments of the supream Judg, nor do they act by any Physical Virtue communicated. For neither do Instruments properly so called perform the work of the principal cause as its Vicars or Substitutes, so as to perform the same action with the principal Cause, though after a manner derived and communicated from the said principal Cause; but they are only Con-causes and Co-workers, and unless the Artist did work they should do nothing; and when the motion of the principal Agent ceases, they also cease from their action.

An Instrument directed by the principal Cause acts beyond its own Ability.

As to the example about the motion and impulse of things hurled, it does not sufficently prove the force impressed upon Instruments. For after what manner that motion of things hurled is caused, is not sufficiently manifest, and much controverted amongst Philosophers. It is most likely that this motion is made by the Air, or through means of the Air, and by the force of the throw. For no man could yet ever tel what that virtue is impressed by the Thrower, & how it can be imprinted by the local motion of the Arm, somtimes immediately, otherwhiles mediately as by a Sling where it sticks; how again it is so suddainly lost and destroyed. And there are doubtless more absurdities which follow this Opinion, and therefore it cannot be allowed to confirm the received Virtue of a separated Instrument.

The Cause of the Motion of things hurled.

And as to those examples of artificial Engines, as Clocks, Watches, Water-works; these things are artificial, in which the motive faculty it self, which is wholly natural, is not communicated by Art to those Engines, as appears by the weights hung on by the spring: but that motion is directed by Wheels artificially made. But it is far otherwise with natural Agents.

Some do yet endeavor to declare the nature of a separate Instrument by the Example of a red hot Iron, which sets Tow on fire. For they say, the Heat of the Iron doth produce fire Instrumentally, by virtue of that fire which heated the Iron, and it acts now as its Instrument, no longer conjoyned, but separate therefrom. For that fire which heated the Iron may now be extinguished and put out. But in good truth the hot Iron does not set the Tow on fire by a power communicated from the absent fire, but by the fire which is in the hot Iron having by its smal Atomes insinuated it self.

And therefore these are words under which no truth is contained, that the principal Agent transmits its action by a virtue derived from it self: but the whol nature of an Instrument consists herein, as hath been said, that it produces an effect more noble than it self, and that not like it self, but the Artificer. And this is the common Condition of every Instrument. And therefore an Instrument cannot be divided into a conjoyned Instrument, which acts and operates by somthing participated in a successive being; and a separate Instrument which acts by somwhat participated inherent therein. For it is the nature of every Instrument to operate by somwhat participated from the principal Agent in a successive being. And as soon as that successive Influx of the principal cause ceases, that whol instrumental action ceases also: but that which acts and operates by some participated vertue inherent in it self is not an Instrument, but operates now as a principal Agent; nor does it act above its own ability, which is essential for an Instrument to do. In a word, that Agent whose Effect answers and is equal to a virtue formally inherent in it self, is a principal, not an Instrumental Agent; nor is there any Agent in Nature which receives virtue from another thing permanently inherent in it self after the manner of an Instrument, or which acts by a vertue communicated thereto, and permanently inherent in it self as an Agent *wherewith*; but every thing that so acts, acts as the Agent *which*, as the most learned *Fienus* rightly speaks to this point. And therefore the Seed also sent forth by a Plant or Animal, because by an implanted Vertue though it be no longer governed by another thing it can shape the body of a

Wherein the nature of an Instrument consists.

Plant

Plant or Animal, is no Instrumental Agent, because it acts not as an Instrument; but a principal Agent, because it acts as a principal Cause. Now that this Vertue cannot flow from any thing but the Soul implanted in the Seed shal be proved hereafter.

Chap. 6. *That the Seed hath the Soul in it, and that the Soul in the seed shapes the Living Body.*

That the Seed is animated.

ALL which things when the diligent Searchers of Nature had considered, and knew that al things which were made by Nature or Art were made by that which actually is, and that whatsoever moves ought to have an actual Being, nor were ignorant that a thing unanimated could not be the principal Cause of an animated Body, but that a thing animated was produced by that which is animated as the principal Cause, and that such noble actions they saw could not be attributed to an accident alone, not governed by the Soul, nor present therewith: they concluded rightly that the Seed it self is animated, and hath a Soul in it. Nor is this Opinion first sprung up in this Age; and therefore it is falsly traduced and opposed by some as a new Opinion: but the most excellent Philosophers and Physitians of al Ages have maintained the same; *Hippocrates*, *Lib. de Diæta*; Plato *in his Timæus*; Aristotle, 2. *de generat. animal. cap.* 1. & 3. (save that he saies the Mind comes from without) *Galen*, 1. *de sem. cap.* 7. & *Lib. de marasmo*, *cap.* 1. Themistius, 2. *de Anima*, *text.* 6. Philoponus, Zimara, 2. *de Anima*, *text.* 43. Jacobus Forolivienſis, 2. *in Art. Medic. quest.* 38. Jul. Cæs. Scaliger, *Exercitat.* 6. Cardanus, 2. *Contradict. tr.* 6. *Contrad.* 17. Argenterius *in Artem parvam*, *tit. de Temperam.* Thomas a Vega, *super Artem parvam*, *cap.* 47. Christoph. a Vega, *Art. med. Lib.* 1. *cap.* 3. Volcherus Coiter, *Lib.* 2. *controvers. cap.* 9. Zabarella, *de Animæ facult. cap.* 11. Mercatus, *Lib.* 1. *part.* 4. *class* 1. *quæst.* 98. Capivaccius, *Lib. de fœt. format.* Joubertus, *in cap.* 5. *Lib.* 1. *Galeni de facult. natural.* Archangelus Piccolhomineus, *Lib.* 1. *Prælect. Anatom. prælect.* 3. *Fortunius Licetus* every where in his Books *de spontaneo Viventium ortu.*

Authors who hold the seed to be animated.

And although (as was said before, Chap. 3.) Authors are here of two Opinions, whiles some say the Souls of al Living things are communicated by the Generators in the Seed, and others except the Humane Soul: yet it wil be sufficient if it can be proved in general of Plants and Animals; but whether or no the same Reasons hold good in the generation of Man, and whether the Generation of Man have any thing peculiar, we shal consider in the last place.

What is the Nature of the seed

And for our better proceeding we must first say somthing of the Nature of Seed, and that not as the common fashion is, of the Seed of Man, but in general of al Seed, inasmuch as Plants and Animals are propagated thereby. Touching the Nature indeed of Seed there are divers Opinions of Authors, and most hold that it is an Excrement. For they say that Seed being a thing according to Nature, is either a part of the Body, or an Aliment, or an Excrement of an Aliment. That it is no part properly so called, nor an Aliment of the Body, it is so manifest that there needs no enquiry thereabouts. Therefore they conceive it remains that it must be an Excrement. And therefore they say that the Seed is the remainder of that Blood which is distributed into al the parts of the Body, and can nourish al parts; and because it is voided forth they say it is an Excrement. But this reasoning offends against the Laws of Demonstration; since Seed is bred not only in Animals of Blood, but in Plants without Blood; and though the Seed which in Animals is voided forth may in some sort be called an Excrement, yet this does not betide al Seed, viz. the Seed of Plants. Moreover, the Seed of Animals is not only the superfluity of Blood, which therefore because it is superfluous (as the Menstruous Blood is an Excrement) it ought to be expelled, but by a primaty Intention of Nature, as a thing most necessary it is made of the best Blood by the Sperm-making Faculty. And therefore in the foregoing Argument there is an insufficient Enumeration, and besides the Part, the Aliment, the Excrement, there is a fourth, viz. the Fruit. For the Seed is the Fruit of a living Creature brought forth to that end that its like may thereby be engendred. And therefore *Epicurus* (as *Plutarch* hath it, *de Placitis Philosophor.*) called it an abstract of the Body and Soul, and as the Author of Medicinal definitions relates, *Zeno Citicus* defined the Seed after this manner. The Seed is the Abstract of a Man, and a Mixture of the Nature of his Progenitors, which a man transmits with the moist part of his Soul; being such a thing as that from whence it was voided. Yea, and the holy Scriptures teach, That the Earth by the Divine Benediction brought forth the Herb seeding Seed, the Fruit-tree bearing Fruit, and every thing having its seed in it self, according

according to its kind; where the Fruit and the Seed are one and the ſame thing. And if any man eſteem more of the Authority of *Ariſtotle* in this point than of the holy Scriptures, let him conſult with *Ariſtotle*, who in 1. *de Generat. Animal. cap.* 18. writes, That the Fruit is either the Seed, or that which contains the Seed in it. And ſince it is manifeſt in Plants, as alſo in Fiſhes and Birds, that the Seed is not ſimply an Excrement, but ſomwhat produced by the Generator, which hath its own peculiar Quantity, Figure, and Conformation; why ſhould the Seed be counted an Excrement in other Animals, although it be voided in a liquid and fluid Form; ſince the ſame proceeds from it which proceeds from the Seed of Plants, Fiſhes, and Birds.

But if you wil cal the Seed before it goes away and is ſeparated from the Generator a part of the Animal, you ſhal commit no abſurdity. For (which is chiefly manifeſt in Plants) it both cleaves unto the whol Body, and is informed by the ſame Soul whereby the whol Body is informed. Yet becauſe it is generated to that end, not that the Generator may be thereby conſtituted, but that it may be ſeparated from the whol, I conceive it may more fitly be called the Fruit.

What Seed is.

Seed therefore as it belongs to al living Bodies is a Body formed by the Generator, full of inbred heat, profitable to propagate any ſort of Soul; or, it is a Body produced by the Generator, out of which a living Body ariſes of the ſame ſort with that from whence it came. And indeed in the Seed of Plants that ſame innate Heat is in an Oyly and Fatty Form, and hardly in any part of the Plant is there more Oyl than in the Seed: which appears at leaſt hereby, in that from the Seeds of Plants a great quantity of Oyl may be ſtilled and preſſed; as is manifeſt in Line-ſeed, Poppy-ſeed, Hemp-ſeed, Juniper Berries, Almonds, and other ſuch like. In ſuch Animals as breed Eggs 'tis repreſented in the form of an Egg: in ſuch Creatures as bring forth live yong ones the innate Heat is in a ſpirituous form, and therefore it eaſily exhales and is diſſipated, unleſs it be preſently received or conceived by the Womb, and cheriſhed by the warmth thereof.

Here nevertheleſs it is to be obſerved that the name of Seed is taken, ſomtimes more largely, other whiles more ſtrictly. The Seed is largely taken for al that Body which ſerves for the propagation and generation of a living Creature. But ſtrictly taken it is a moſt ſimple ſubſtance, or a certain ſpirit in which the Soul and Formative Faculty is immediately ſeated, and containing in it ſelf the Idea or Model of that Organical Body from which it is taken, and therefore having in it the Power to Form a Body like to that from whence it was taken, and to perfect it ſelf into an Individual of the ſame ſort with the Generator.

Now the Seed conſiſts of two Subſtances, the Matter, and the Form. The Matter is that ſame Body or bulk of the Seed, which is various in different Creatures, and of another kind in Plants, and variouſly diſtinguiſhed by the admirable wiſdom of the Creator, according to the Nature of every ſort of living thing; of one faſhion in Fiſhes, another in Birds, another in other Animals. And that matter again conſiſts of two parts, of which one is a thick ſubſtance, another ſpiritual, or (as *Ariſtotle* ſaies) a Spirit and Nature anſwerable to the Element of the Stars. And the Spermatick Faculty is as the Form being the Original of motion, and which hath ſo great a power, that *Plutarch*, (*de Commun. Notionib.*) ſaies of the Seed, that it is more magnificent and great than that from whence it came, and of which it was bred; and that which *Ariſtotle* ſaies in general of Principles, 5. *de generat. Animal. cap.* 7. is chiefly true of the Seed, viz. That Principles though ſmal in bulk, yet are exceeding great in faculty and ability. Which power of the Seed *Seneca* alſo admires, *Lib.* 2. *Quæſt. nat. cap.* 6. *Let us conſider* (ſaies he) *what a mighty power ſmal Seeds do ſecretly put forth; and thoſe whoſe ſmalneſs doth hardly take up any room betwixt the joyning of two ſtones, they grow ſo ſtrong as to draw aſunder huge ſtones, and diſſolve the Monuments of the dead.* And *Gregory* the Great, in his 26. *Homily upon the Evangeliſts*, writes excellently of the wonderful nature of Seed: Behold! in one grain of the ſmalleſt Seed lies the whol bulk of the Tree that ſhal ſpring therefrom. For let us ſet before our eyes the greatneſs of a Tree, and think with our ſelves what original it had which is grown ſo great; we ſhal doubtleſs find its original to have been a ſmal Seed. And now let us conſider where (in ſo ſmal a grain) lies the ſtrength of the Wood, the roughneſs of the Bark, the greatneſs of the taſt and ſmel, the plenty of Fruits, the greenneſs of Leaves. For if you feel a grain of Seed it is not firm or hard, whence then comes the hardneſs of the Wood? it is not rough, whence then came the roughneſs of the Bark? it is not ſavory, whence then is the taſt of the Fruits? It hath no ſmel, and how then came the Fruits to be ſo fragrant? It hath no greenneſs in it, whence then proceed the greenneſs of the Leaves? All theſe therefore lie hid in the Seed as

one and the same time; yet are they not produced out of the Seed al at once. For out of the Seed the Root is produced; out of the Root sprouts a Branch, out of the Branch grows Fruit, and out of the Fruit is produced Seed again. Let us therefore ad that the Seed also lies hid in the Seed.

Hence therefore some do not unfitly term the Souls Idea's or Patterns, because in them as in a Prototype, the Nature and Fabrick of al Visible Bodies which they form and shape, and of al accidents which they produce in their Bodies, is comprehended.

But that the Principal part of the Seed is the Soul, and that therefore the Seed is animated, shal be anon proved by firm Arguments, wherewith a mind desirous of Truth may be satisfied. But because I see that most men now adaies do not regard so much what is true as what is old, it were worth the while to alleadg the Authorities of ancient Philosophers and Physitians; but we have done that already in the beginning of this Chapter. Also the Authorities of Divines (both Greek and Latins) might be produced; but because most of them speak only of the Soul of Man, of which we shal speak hereafter, it shal suffice in this place to alleadg only the Authority of *Aristotle*, who 2. *de Generat. Animal. c.* 1. thus writes: *All things whatever are made by Nature or by Art are made by that which is actually out of that which is potentially such or such. The Seed therefore is such a thing as hath such a Motion and Principle in it self that the motion being finished every part exists, and each part also is animated.* And in 2. *Phys cap.* 3. *text.* 31. *The Seed, and the Physitian, and he that advises with him, and every Efficient, are all of them Causes, whence there is a Principle of Mutation, Rest, or Motion.* And more such like places *Scaliger* produces, *Exercit.* 6 *Sect.* 7. Also consider what follows, out of which it manifestly appears that though *Aristotle* saies the Soul is potentially in the Seed, yet that he holds it is really there. Which appears by the example of a Geometrician sleeping, waking, contemplating, which he makes use of. For as the Geometrician sleeping and waking hath the power to contemplate, the former a remote power, the latter a neerer power, each of which notwithstanding presupposes an Act, such as is not in al men, but only in a Geometrician; so in a Tree (for examples sake) in the Winter time when it grows not there is a neer power to grow, because it hath Organs necessary to cause it to grow already perfect: but in the Seed there is a remote power, because it is as yet destitute of Organs; yet each power pre-supposes an act, and neither the Seed nor the Tree could be called potentially such, unless the Soul were present.

What Soul is in the Seed.

But it is demanded, What Soul is in the Seed? *Aristotle* indeed saies, That the Generation of a living thing is the participation of the first Nutritive Soul with the inbred heat. And in 2. *de generat. animal. cap.* 3. he writes, That a Man lives first the life of a Plant, then of an Animal, and lastly of a Man. But this is not so to be understood as if three Souls came at distinct times. For every living thing (even according to *Aristotle*) hath but one Soul, whereby it is that which it is. And therfore in al seed whatever there is presently the whol Soul, which nevertheless does at first form the Instruments necessary for Nutrition; which because it is chiefly and almost only conspicuous in Plants; a man is said to live first the life of a Plant. Afterwards in process of time the Instruments both of Sense and Motion are formed in Animals; which being perfected, a Man is then said to live the life of an Animal, and of a Man. For neither (as I also shewed in *Lib.* 6. *Physicæ, cap.* 1.) the Vegetative and Sensitive, or the Vegetative, Sensitive, and Rational, are peculiar and general Forms or three Essences, but only general Conceptions arising and constituted from the comparison and agreement of living things, which exist no where separated save in the Mind of Man; nor is the Nature of any Plant perfected only by the Vegetative Faculty, but every Plant hath a specifick Form, endued with a vegetative power indeed, but yet with other Faculties also.

This Opinion of *Aristotle* (and indeed the very Truth) concerning the presence of the Soul in the Seed most excellent Philosophers and Physitians of al Ages have acknowledged, whom I cited in the beginning of this Chapter, and especially *Julius Cæsar Scaliger*, *Exercit.* 6. *Sect.* 7. *et sequent*, and amongst later Writers, the most learned *Fortunius Licetus*, (who as elsewhere, so in *Lib.* 4. *de spont. vivent. ortu, cap.* 32. propounding as it were the Sum of what he had taught elswhere) writes, That the Seed is an imperfect Animal, and that a Lyon and the Seed of a Lyon are Univocals, and have the same Soul for their Essential Form, and differ only in the Organization of their Bodies; and *Lib.* 1. *cap.* 74. That the Father then truly generates when he casts out his Seed, his Soul being parted by partition of its subject, and of one being made two; and that which remains in the Seed being cherished by the temper of the Womb and obtaining a fit matter exercises its Faculties thereupon,

upon, and forms it self a body fitted with those Organs it stands in need of, to perform the other operations of life: so that the seed is an Animal and living, only wanting a multitude of Organs; and the Fathers generation is not performed in the Womb after the Fathers's death, but when he issues out his Seed.

'Tis proved that Seed is animated.

But I will not contend only by Authorities, nor is it fitting to begin the proof of this point from the Generation of Man, since that were contrary to the Laws of demonstration. For some do not a little involve this point with obscurities, when they dispute whether the seed be animated, not sufficiently explaining their mind, whether they understand the Seed of Man, of brute Beasts, or of Plants; [or when they cannot satisfie themselves, but remain doubtful, they affect obscurity on purpose that others may not easily understand what they think. Lest therefore any doubt may remain in a matter so serious, by a Living thing we understand a substance wherein there is a Soul actually, and our Question is whether the seed be such a substance] which they ought by any means to have declared. For there are some who will not grant that any seed is actually animated; others that the seeds of Plants indeed are animated, but they deny the seed of animals especially of Man to be actually animated. But I conceive it most probable that all seed is animated. And therefore we undertake to prove in general concerning all living things, that their seeds are animated. Now those most evident and firm and hitherto unanswered reasons which have induced most renowned Men to be of this Opinion, are these. The first is this, that the operations of the soul are most manifestly discerned in the seed. For it is a maxim granted by all Philosophers; every thing that moves is actually in Being. And these three follow one another reciprocally; to be, to be able, to operate. And therefore Operations bring us to a power, and a power to an Essence. For such powers do flow from the very Essence of the soul, and they are inseparable from the soul, nor do they pass from one subject to another. And as *Plenius* speaks well, it is so absurd as nothing can be imagined more absurd, to hold that conformation, as also nutrition and augmentation, which begin with the soul it self, do flow from a Principle which is not not vital. Not can a vital power communicate its Virtue to another thing which is not vital. Since therefore the operations of the soul appear in the seed, we do thence rightly and necessarily conclude, that there is therein a soul furnished with the powers to exercise these operations. Now that the seed hath Motion and Action is as manifest as that which is most manifest, and so often inculcated by *Aristotle*, when he calls the seed the Beginning of generation and Motion (1. *de generat. Animal.* 2. & 21.) and the Beginning of the Form or Species, which works the Menstrual Blood into its own proper shape. 1. *De generat.* 20. and 4. *de generat.* 1.

The Operations of the Seed.

The first Principation.

Now these are two operations in the seed which bring us most certainly to the knowledg of the soul lying hid, viz. The quickenning of the seed and Conception; and afterwards the shaping of all the parts necessary for the performance of the vital actions. For in the first place, every seed (as is manifest in Plants) is preserved by its own soul, and for a certain season remains fruitful, some the space of a year, others two years or more according to the difference of sorts; and as long as it is perfect and uncorrupted, and hath gotten a fitting place, present nutriment and external heat to excite the same, it is apt to grow up into a Plant of its own kind. It seems indeed an absurdity to *Libavius* and some others, that grains of Wheat lying in the Corn-loft should actually live, but he shews no reason why it should be absurd. Contrarily it is more agreeable to reason that seeds should live. For although in the seeds of Plants there is no motion apparent to the sense: yet the soul lying hid within is not idle, but it vivifies the seed: after the same manner as in Trees in the Winter time no action appears to sense, and yet they are not destitute of their soul, but are enlivened by the same concealed within them, which in the spring time by manifest actions does again discover it self; and the same happens in seeds. For Seeds whiles they live are fruitful and fit to be sowed, but those which are dead are not fit to be sowed, nor will any Plant spring from them. And if seeds were not alive, whence comes it to pass I pray you that being only mortified and cherished by Heat they presently begin to sprout?

The Second, the shaping of the Body.

The second operation is the forming and shaping of the living Body: an admirable work truly, and wherein as (*Galen* speaks) there appears the greatest Art and Wisdom imaginable. For if there be any work in nature admirable, and wherein we must be fain to acknowledg our own Ignorance and to admire the infinite Wisdom and Power of the Creator, it is the shaping of the Child in the Womb, the Chick in the Egg, and the Body of a Plant out of the seed thereof. For who does not admire that the Bodies of Plants and Animals are so artificially framed, and in respect of Magnitude, Number, Figure, Order, Situation, Colour, Smel, and other things, so formed, as to transcend all the Art and Industry of all the Artificers

in the World? *Hippocrates* truly every where, especially in *Lib. de Alimentis, de Corde, de Articulis, in epidemiis*, cals Nature most Sagacious, most Just, most Artful, most Provident, most Discreet. *Aristotle* compares her to a prudent Houſ-holder rightly mannaging all things, who in generation makes nothing superfluous, nor omits any thing necessary, changes nothing, nor produces any thing sooner or later than need requires, does nothing in vain; so that there is no member in a living body but hath its action, nor is there any action which wants its member or Instrument. And 1. *de part. Animal. ch.* last, he admires the Wisdom and Power of Nature even in the meanest things. *Galen* also in his 16. *de Usu partium, ch.* 1. does teach that distributive justice is in nature very eminent, and in 15. *de Usu partium, chap.* 1. that Mans words cannot express the wisdom of Nature; and in the same Book, *ch.* 7. he saies that Nature is more skilful than the skilfullest Artist. Which in 17. *de Usu partium, cap.* 6. he proves by example of *Phidias*, who though he had with such admirable workmanship engraven in a Ring *Phaeton* in his Chariot with four Horses, that the parts of the four Horses might be discerned distinct one from another, and the sixteen Feet of the Horses were visible: yet the workmanship of nature in the Thigh of a Gnat is more admirable than that of *Phidias*, in all those members of the four Horses. For besides the Articulation, there is found therein a faculty to move, nouriſh, and grow. And how great the Wisdom and Power of Nature is, even a Plant the loweſt sort of living things does sufficiently shew; in which there is so much variety and beauty, in figure, colour, scituation, that no man can sufficiently admire, much less imitate the same. And from the Praises of Nature *Galen* fitly raises himself in many places to praise the God of Nature; and no Philosopher is more large in setting forth the praise of God, and all his Books of the use of the Parts of the Body (*as himself saies*) are nothing but an Hymne in Praise of the Admirable works of God. But especially *Lib.* 3 *de Usu part. cap.* 10. he writes excellently indeed; *But truly* (saies he) *if I should speak any more of these kind of Cattel, men better minded might justly be offended at me perhaps, and say that I defiled that sacred discourse which I frame as a true Hymne in praise of our Maker, and I conceive that herein is true Piety, not to Sacrifice to him many hundreds of Oxen, or to burn* Cassia Lignea *and a thousand other sweet perfumes and Oyntments, But if I first know my self, and then declare to others what his Wisdom is, his Virtue and Goodness. For in that he would adorn all things with convenient furniture, and suffer nothing to be deprived of his benefits that I count as a token of most perfect Goodness; and in this respect his Goodness must be celebrated by us with Hymnes. But to have invented all this, how and after what manner every thing should be adorned, is a point of the highest Wisdom; and to have been able to bring to pass al that he pleased, is an argument of an invincible and unconquerable Virtue and Power. Thou must not therefore so admire the Sun, Moon, and universal order of the other Stars, being so exceeding artificially marshalled & disposed; nor let their Greatness, Beauty, perpetual Motion, or so certainly described Circuits render thee so astonished as to think these sublunary things mean in comparison, and void of all ornament. For here also you shal find a like Wisdom, Power, and Providence. For do but consider the matter whereof every thing is made, and do not vainly perswade thy self, that of menstrual Blood and Seed an immortal Creature could be made, or one that is impassibble, or alwaies movable, or as bright and fair as the Sun. But as you estimate the Art of* Phidias, *so consider the Art of the Maker of all things. But you may perhaps be astonished at the wonderful Ornaments of the Statue of* Jupiter Olympius, *the bright Ivory, the store of Gold, the largeness of the whol Image. But if you should see such an one of Clay, you wil pass by the same it may be with contempt. But so wil not an Artist do nor one that is able to judg of the works of Art, but he praises* Phidias *as much, if he see his workmanship in common Wood, or Wax, or Clay. For a vulgar and unskilful Eye is astonished at the richness of the matter, but an Artist is only amazed at the Beauty of the workmanship. Come on therefore, be thou a skilful Naturalist, that we may not term thee a rude Plebeian but a true Philosopher. Leave the difference of matters, and consider the bare Art it self. When thou observest the Fabrick of the Eye, think that it is the Instrument of Seeing, and when thou viewest the Foot, think that it is the Organ of Walking. But if thou thinkest of Eyes made of the substance of the Sun, and of Feet made of pure Gold, thou forgettest the matter which is Bones, and Skin, and Flesh, whereof they are made. Remembring that therefore consider whether light be an Heavenly Substance, or an Earthly Slime: for so give me leave to call the Mothers Blood flowing into the Womb. As therefore if you give* Phidias *Clay to make an Image of, you wil never require of him an Ivory Statue; after the same manner having given Blood to the Work-master, you cannot receive from him a Sun, or a Moon, or such a bright and beautiful Body. For those Bodies are divine and Heavenly, and we but Statues or Images of Clay, and yet the Art of the Work-master is equal in both.* So far *Galen.*

Galen *sings an Hymne to God the Creator.*

Yea

Yea, and this Work can hardly be sufficiently admired, concerning which *Franciscus Titelmannus* writes excellently and piously, *Lib.* 8. *Physic. c.* 11. (I will give you the whol place) and thus he saies. *Is it not superadmirable that of a smal Seed (taken from some Herb or Tree) cast into the Earth, a green Herb should spring up, or a Tree, and that the same in proceß of time drawing its nourishment out of the bowels of the Earth should joyn to it self its just quantity, and fit all its parts according to the condition of its own Nature, with so beautiful a variety, so comely a disposition, and so admirable an order that the wit of Man is not able to comprehend the Workmanship that is in one smal Herb? For consider as a Tree grows up from the Seed, how it sends its Roots into the Earth beneath, and fixes them so fast, makes them stick so close in the bowels of the Earth that after a little time it can hardly be stirred or plucked up without great violence; how it sends its Stock and Trunk upwards, which outwardly it cloaths with Bark as with a Coat, against the inclemency of the Air, and the injuries of cold and heat. And in the inmost part the marrow is placed, and round about Veins great and smal are dispersed through the body of the whol Trunk; and they in an admirable order springing, the lesser from the greater, through which all parts draw nourishment to themselves. And in the upper part how wonderfully do the Leaves spring out of the Branches, wherein also we behold a wonderful Connexion of Veins and Arteries. Also the Leaves have all the same shape, the same smoothneß or roughneß, a like longitude and latitude well-neer, the same color, tast, and smel; and in every respect Trees of the same kind are exceedingly one like another. I pass over the beauty of the Flowers, the sweetneß of the Fruits, and in both a wonderful Artifice. And all these Originally spring from the Vertue of one Seed. And in the Seed likewise of a living thing, and consequently of a Man (out of which the Child grows as to its Body) is not that alone exceeding wonderful, that by reason of the Vertue which is in so exceeding vile altogether deformed and filthy matter, such a decency of Members, so beautiful a composition, so convenient an order, so effectual a disposition of Members, so rare a conjunction of parts should arise? namely, That beneath a broad part should be shaped upon which the whol body might firmly stand, and move from place to place; the extream part whereof should have a manifold division, so that the matter should be carved as it were into particles, viz. That the Feet should have Toes, and that these parts again should have such an order that that which is in the first place should be longer and thicker than the rest, and so to proceed gradually, as that the last Toe is of all the smalleß and the shorteß. Likewise, That these parts at the end of the foot should be so regularly and generally five in number, that he is counted for a Monster that hath six. Also that each of these parts hath its joynts wherein they may be bowed, and the first and greateß hath only one joynt in the middle, the reß every one two. And all these things are manifestly apparent in the composition of the Foot and Hand to him that shall look no further than the out side. And in the uppermoß Part of the Body, how there is framed with rare Artifice a round part, which is covered above with the Skull, of so hard and indissolvable a boney substance that lying many yeers together in the Earth it cannot be consumed. Which Skul is covered with fleßh and skin, whence flow the Hairs which cloath the part all over. But under this Skul is formed a certain noble and moßt tender substance which we term the Brain, and that in several parts variously formed that it might be a fit receptacle for divers Vertues, and the Organ of sundry noble Operations. In which upper round part the Eyes also are placed, beautifully formed in their sockets, yet so as they might be moßt readily moved, which also have their Eyelids and Eyebrows. Under these the Noßrils, and on the sides the Ears; and under the Noßrils the Mouth-hole to receive the Meat, and round about the Jaw-bones ful of Teeth; the foremoßt of which at the entrance are thin and sharp to cut and mince the Meat, but the hinder are more than twice as thick, which like Mill-stones grind what the other hath cut into smal particles, in which regard they are also called Grinders. But on the back-side of the Head all is shut up, and no opening to be seen: but there are strong Nerves, and wonderful Joynts which faßten the Head (the upmoßt part) to the Shoulders beneath, so that though the Head do not touch the Shoulders, yet it is beautifully supported by them without burden by interposition of the Neck. And hence from the Shoulders (as it were two Boughs) the Arms are stretched out for the performance of any work, which in the middeß (namely the Elbow) are made to bend, and have their utmoßt parts orderly divided into Fingers, as was said before of the Feet. Moreover that same moßt noble member the Heart is so wonderfully seated in the middeß of the Body, having the Lungs placed round about to fan and temper its heat, drawing the Air continually in by their respiration like a pair of Bellows, and so tempering its Heat: also having the*

Liver

Liver its neighbor the Work-house of Blood, and the Stomach as the Cook of the whol Body, receiving the Nourishment of the whol: also the Spleen, the Kidneys, the Guts, all wonderfully knit together and rowled about. That all these things, I say, which we have only touched at, and other things hid within much more wonderful, should be so orderly, so perpetually shaped in the Body of a Man, yea, or of another Creature, by the power and vertue of so vile a substance as the Seed, who can chuse but count this the greatest miracle in the World? Had not the Psalmist reason to say to the O Lord, thy Knowledg is made wonderful in me, and strengthened, and I cannot attain thereunto? And have not we like reason in the Preface of this Book to cry that Men carry Miracles alwaies about them more wonderful than all the Miracles in the World besides? And truly it would not seem so great a wonder if we should ever, That God by his Omnipotent Power of himself did frame all this connexion and disposition of Members which we see in our selves. If as in the beginning he created Adam of the Earth, and Eve of his Rib without the power of any seed, to imp body the Earth for matter, and administring all the power himself; so he himself also should frame our bodies in their most beautiful disposition and proportion. Also, if as at the first he created Trees and Herbs without the Vertue of any seed; so he should now by his all-powerful Command cause them to spring up out of the Earth. For we know that to him nothing is impossible, and nothing difficult. It is to us no news if he does great things, or without resistion; He alone does wonderful things. But that this disposition of the Body of Man should proceed from the Vertue and Power which lies hid in the Paremt seed (a most filthy, and hardly to be named substance, which no man beholds without abomination) and that therein so rare a vertue should lie concealed to make and shape so admirable a body; that the whol efficacy of this wonderful disposition of parts should really exist therein, this justly adds weight unto our consideration above measure, this renders us amazed and astonished, and compels us to cry out, and to confess with open mouth, that he is not only great in himself, nor only great in great things, but that even in the most abject, contemptible, and smallest things, he is full of Glory. So far *Thelmannus.*

The shaping of the Body of a live Creature is the work of the Soul.

But since certain it is, That God does not immediately and alone effect al these things which come to pass in the Generation of Living things, but that Nature is constituted, which is the ordinary Power of God, and which performs al the vicissitudes of Generations; the Question now is, What is the immediate Author of this admirable Fabrick in living things, both Plants and Animals. And although *Galen* despaired to find the cause by which al these things are done, and confesses that he could find nothing so much as probable in this point, which made him exceeding sad, *Lib. de fœtu formato, cap.* 6. Yet if he had considered that these Operations were proper to the Soul of every sort of living Creature, he might without great difficulty have known that al these operations did proceed from the Soul which lies hid in the Seed.

That these are the Operations of nothing but the Soul of every living thing, he will easily understand who considers what it is which of a smal Birth makes a large Animal, preserves in Nutrition the same Figure of the Body, left by the continual growth of the parts it should be changed, restores the flesh lost, breeds oftentimes large Veins. Which *Galen* saies he saw in the Head of one, *Lib. de semine*, repairs the teeth which young people do cast, restores every year the fallen Leaves of Trees, brings forth the Flowers and Fruit, in Peacocks and other Birds supplies new Feathers suitable to their kinds. For since it is certain, that the Soul and form of every sort of living thing is the specifick cause of al these operations, and that hence every year each Tree hath its own Leaves restored, of one fashion to the Oak, of another to the Pear-tree, of another to the Peach-tree, and Harts-horns to the Hart in room of those are fallen off, but not the Horns of an Ox, Claws of a Crab, every one according as suits with their particular Nature: What need is there I pray you in the first structure of every living thing out of its Seed, to seek any other cause of Formation than the Soul it self, which is one and the same in the Seed, and in the living body formed? For it is altogether the same work, when the Soul lying hid in the Seed, and drawing matter, shapes the body of a Plant, and when the same Soul repairs the fallen Leaves, restores the Flowers, produces new branches, boughs, and roots. And so since the same operations in the Seed, and in the Plant, are seen in every respect absolutely perfect, they shew that there is the same Principle and Agent in both. And therefore since in the seed it self are performed the operations proper to the soul, why should we deny the soul to be in the seed? For al the faculties of every form, and especially of the soul, are properties inseparably flowing therefrom, and therefore it may be most rightly concluded; Where the faculties and operations of the Soul are found,

there

there the Soul also it self is present, and we easily come by the operations to the knowledg of the hidden Essence and Soul. For if one Faculty were in the Seed, another in the grown body, of what form was that the power, or when went it away, and whither, when the body was formed? It is an absurd thing truly to hold, that the Formation of the Flesh, Membranes, Bones, and other parts, is begun by one faculty, and continued and perfected by another different therefrom; and that so as to continue the work begun with the same thred without any Error. Doubtless one and the same continued Operation, which lasts from the Beginning of Generation to the end of Life, cannot proceed from divers Principles.

This also confirms the same that in Plants we see a Root, or Branch, or also a Leaf only, as in the Indian Fig-tree, being pluckt from the Plant and stuck in the ground, does grow into a compleat and perfect Plant; which is the work of nothing but the Soul present therein. And since the same thing is done in the Seed, we justly conclude that the Soul is present and therein, and performs the same work. Yea, and when we see the same Plant (as Rosemary for example) propagated both from a Seed and Branch we acknowledg the same cause in both cases. For otherwise there would be two different causes of one special effect, and two conforming Faculties of one and the same Plant, which is false and absurd.

To answer this Argument, *Fienus* (truly) labors and sweats hard, *de form. fœt. quæst. 5. Concluf. 6.* but yet in vain. For he saies that a new Plant is produced one way out of the Root and Branches, another way out of the Seed. For of the former a new Plant is not made, but they being severed from their stem are themselves a new Plant; because being cut from the whol they have already a vegetative soul multiplied, but do not acquire the same, by which they augment themselves and attain to their perfection. Contrariwise, that the Seed is no new Plant, because it hath no soul, but it becomes a new Plant by the coming of a soul into it after it is planted in the Earth; or by the soul which is newly produced in the seed after it is put into the Earth.

Fienus his Reason against the Animation of the seed of Plants.

But *Fienus* can by no means thus free himself. For in the first place, though it seem another manner of propagation to the sense, that which is by the Root or Branch, from that which is by the Seed: yet in respect of the principal Efficient it is indeed one and the same, since it proceeds from the same soul. *Fienus* denies indeed (by reason of a pre-conceived Opinion) that the soul of the Plant is in the seed, but he proves it by no reason. Contrariwise, from the operations of the Formative Faculty which are in both alike we firmly conclude the same soul to be in both, viz. in the Seed (for examples sake of Rosemary) and in the Branch thereof. Moreover in the same sence, as a Root, a Branch or a Leaf may be called a new Plant, the Seed may also be so called. For in each there is its Soul, but in the Seed there is wanting the ultimate perfection springing from the Organs. Thirdly, if he grants the whol soul may be in the Slip of a Root, and in one Leaf of a Tree, and that by cutting off the soul is multiplied, and that the soul which before was but one in number, viz. while the said Root, or Branch, or Leaf did grow to the Plant, by cutting the same off is multiplied; why does he not grant that the same multiplication may be made by the seed? especially since al seeds are rarely fashioned, and some of them have a more artificial shape than the Root of an Hop or any other Plant, or the Leaf of an Indian Fig-tree? The same Operations in both do argue (doubtless) the presence of the same Soul in both.

We do therefore rightly argue from this wonderful Fabrick of the Body which is made in and of the seed, that the soul is present therein. For, *whatsoever is made by Nature or by Art must be made by that which hath an actual Being; and that which moves must have an actual Being*; and every immediate efficient Cause must necessarily be joyned with the Patient. And therefore in the generation also of al living things that which forms the Body must be present, and must be joyned to that Body. And that which is yet more, the ministring powers themselves which wait upon the Formative Faculty do al appear in the seed. For the first Operation which is performed in the Seed is in a Plant the drawing of nourishment from the Earth, and in Animals the drawing of the Mothers blood. The second is the Vivification and Animation thereof, or Communication of the Soul thereto. For the Nutriment drawn out of the Earth is inanimate, and the blood also is of it self inanimate. But when of these the parts of a Plant and of a Child are made, they must needs then be animated. But nothing can give a Soul but that which hath it, and therfore the Seed is animated. The third Operation is the separative. Since the Liver is made of one kind of matter, the Stomach of another, the Heart of another, the Brain of another; a Vein, a Nerve, an Artery of another, the Soul in the Seed discerns and separates these matters one from another.

Fourthly,

Fourthly, when these matters are severed by the same Soul each is put in its own place, the Brain and Stomach in one place, the Heart and Liver in another. The first is the Formative peculiarly so called, by which its own shape, quantity, number, and the like, are allotted to each part.

There is no Agent in the seed except the soul.

Secondly, There can be no other Agent here assigned save the seed. For first of al, the Generator himself is many times absent. So in the Spring, when a Plant springs from seed, the Plant which bare that seed is many times dead long before; and while the Animal is in the Womb of the female receiving its shape, the Male which ingendred the same may happen to be dead.

The innate Heat in the Seed is not the Principle of conformation.

Again, Neither can the inbred Heat of the Seed be the Cause of Formation. For though it cannot be denied, that the innate Heat is an Organ wherewith as other actions in the body, so conformation is shaped, yet it is not the primary Cause; since so admirable a work can not be ascribed to a bare quality, as to give to so many different parts almost infinite in number, each its peculiar figure, quantity, number, scituation; but there is need of a far Diviner Agent. Of which *Scaliger*, *Exercitat.* 6. *Sect.* 5. *If* (saies he) *the form comes from without (as they tel us) and in the mean while the matter is furnished with al kinds of perfection; of necessity both the Qualities and Quantities, the numbers, orders, and scituations, must be provided and ordered by somwhat which is within, and in conclusion the whol Body must be shaped by the same internal Principle. Now this shaping of the body is performed, either by a substance, or by an accident, or by both. Not by an accident alone. First of all, because no accident works but in the vertue of its substance. Again, because no accident hath knowledg. But that same Vertue and Power which is Architect of so noble a Temple hath been judged by all Philosophers to be most exceeding wise. It must be therefore framed and built by a substance. And this substance is the Form of the Seed. Doubtless the form of the Seed if it be not a Soul it is a bruit thing: and if it frame the body, it is equal to the Soul. But in growing and restoring of wasted Flesh the soul is it which does all. There must be therefore in the Seed a shaping Soul which comes before that Soul for which it prepares its house. And therefore that former Soul is more wise and noble than this latter.* And a little before: *The Form it self is the cause of this preparation. For it both alters the whol, and disposes of the parts for its own use. Nor when the body arrives to the perfection of its preparation, does it then also arrive to the substantial Form. For the Form it self exists before-hand. And therefore there is no progress made to it, but to its act, that there may afterwards be use made thereof.*

The vertue of the Mothers Womb is not the Cause of the formation of the yong one.

Nor in Animals can the Vertue of the Mothers Womb be the cause of the Conformation and shaping of the Body. For if the Formative Faculty were in the Womb, and not in the Seed, the Father should confer nothing to the Conformation of the yong one, and should afford only a passive Principle, and consequently should not generate. Again, there can be no cause assigned why the Child should be sometimes like the Father, and why Females should not alwaies be ingendred. Thirdly, in Eg-bearing Animals the Conformation is not performed by the Womb, but the Eggs are perfected into Chicken, without the Body of the Hen; as neither the Earth (which to Plants is as the Womb) hath any power to shape the Plant, but al that Faculty is in the Seed. Moreover, if heat brings (as they say) the power of the Seed into act, a Quality engenders a substance. Nor can they avoid the force of this Argument who answer, That this substantial Power is so ordered and disposed by the Generator, that the said Quality being awakened it breaks forth into an act like the Generator. For what I pray you is that substantial power? Certainly unless it be the Soul it is a meer figment, which appears by their own rule, when they say that the next power is reckoned for an act. For since a thing cannot be at once both in act and power, if the next power be an act, certainly it cannot be a pure passive power, but a formal one, and so the Soul it self.

The Objection of Fienus against the presence of the soul in the seed.

Nor is that of any moment which *Thomas Fienus* brings against this argument, *de form. fœtus, quæst.* 5. *concluf.* 6. For seeing he grants that there is no other cause of the Conformation of an animate Body save the Soul, it is rightly hence concluded; That whatever hath in it the Efficient Cause of Formation hath in it the Soul: But the seed hath in it the cause of the Conformation of an animate Body. *Ergo* it hath in it the Soul. Here indeed *Fienus* answers; *I acknowledg the Premises are true; but I deny the Consequence. It is indeed rightly inferred that there is some Soul in the Seed, but not that it is the Soul of the Seed. There is indeed a Soul brought in to the Seed after that the Seed is conceived in the Womb, or planted in the Earth, or the Eg is set under the Hen, when al things are put into act; but*

that

that is not the Soul of the Seed, or which did pre-exist in the Seed, or which was bred in the Stones, the Tree, or the Hen, but the Soul of the young Conception which was afterward introduced thereinto. But in very good deed, how can the Consequent be denied if both the Premises be true? For in a Syllogism, that which is false cannot be inferred from true Premises. He saies nevertheless that the Minor is false, and he denies that the soul which is the Cause of Conformation is the soul of the seed: but falsely. For it must be shewed, as hereafter shal be said, what is the cause of those operations and of the conformation in the seed before the soul is come, according to his opinion. Moreover since he saies the soul is not present til all things be actuated, he ought to shew what is the Author of that same actuation and conformation, in Plants, Eggs, Bruit Beasts, before the soul comes. Thirdly he ought to have told us, whether the Souls also of Plants, Birds, and Beasts, are introduced, and from what cause they proceed. Doubtless when some Seed is cast into the Earth, or in any place is moistened with water (without any other cause) first it puts forth a Root, and a little after it begins to sprout. What I pray you is the cause of this operation and formation, save the Soul already pre-existent in the Seed? Or if it be not the Soul pre-existent in the Seed, Let *Fienus* shew whence it should afterwards come.

And this Argument which hath hitherto been propounded and explained, drawn from the operations of the Soul appearing in the Seed might alone suffice to perswade a mind not pertinacious, but desirous of truth, that the Soul is in the Seed: howbeit there are other Arguments evident enough to prove the same.

Like would not beget its like, if the Seed were not animated.

For in the second place, whatsoever ingenders its like must needs communicate its Essence to the thing ingendred; otherwise it would not be essentially like it. But every living Creature begets its like, *Ergo* it communicates its Essence to the thing ingendred; and consequently not only the matter, but also the form, whereby the Essence of a thing is chiefly accomplished. And if this were not so there could be no univocal Generation, and the Generator could give nothing but the matter, nor could any man tel us whence the Soul should come; when frequently the Generator before a Plant or Animal is made of the Seed may come to die, and afterward nothing should be found to form the Plant or Animal save external Heat. Thus the Seeds and bulbous Roots of Plants are sometimes kept many yeers before any Plant grow therefrom, the Plant which bare the Seed or Bulb being long since dead. So out of an Egg even by the Heat of a Furnace a Chick is hatched, the Cock and Hen from whose copulation the Egg proceeded, being long since kil'd and eaten. And questionless if there were not in the Seed an active Principle communicated by the Parents, the Parents could not be truly said to generate, since they should afford only the Matter.

Thomas Fienus indeed makes answer, *de Format. Fœt. quæst.* 6. that the Parents do herein really and actively generate, in that they afford the Seed and Matter of Generation, and imprint thereupon all dispositions necessary for the Introduction of a Soul. But this is the Begging of the Question. For we deny that *that* which only affords the matter of Generation however disposed to fit it for the reception of the form, does communicate an active principle and truly Generate. For all these dispositions do belong to the matter, and he that does not communicate the principle of acting, he cannot be said actively to ingender.

A Thing Inanimate cannot ingender that which is Animate.

Thirdly, If the Seed had no Soul in it, and yet should produce a Creature with a Soul in it, the more noble should be produced by the less noble, and the Virtue of the Seed should produce a Substance, which is absurd. For nothing acts beyond its ability; also that which is not animated should perform actions proper to the Soul, Conformation, Nutrition, Auction, Attraction; should make Bones, Flesh, Membranes: all which actions are performed at the first conformation, which happens soon after the Beginning of the Conception.

And though it be objected by some, that an Agent by virtue of another thing may produce an effect more noble than of it self it were able to compass: yet if this be done, it must be done when the principal Agent is present, and not when it is absent, which does not happen in generation. For the Father may be absent from the place where Generation is made, yea and he may be dead before that time. So also the Mother may be absent or dead, as it happens in Chickens, which are hatched by the Heat of a Furnace, or by some Fowl of another sort.

How Live things are generated.

All the Premises therefore being considered, it is most rightly determined, that the soul it self is in the seed, and as *Zabarella* wel saies *de Facult. Anim. cap.* 11. that Living things when they generate their like do communicate some of their Matter and some of their Form, when they afford an animated seed furnished with the same vital faculty which was in the Generator.

Souls are co-extended with their Bodise.

For though the Souls of living things of themselves have no Quantity nor are divisible: yet according to the extension of the matter wherein they are they themselves are extended, which *Fortunius Licetus* hath proved in two Book *de Animæ Coextensione Corpori*, and when it is divided they are divided, or rather multiplied, and yet they themselves are neither greater nor less than they were. So the Soul which is in a smal Twig that first shoots out of the Earth, is no less than that which is afterward in a tall Oak; nor is the Soul of a Calf less than that of an Ox. After the same manner the Soul diffuses it self into the Nutriment which is newly adjoyned to the Body, and so according to the extension of the Body which it informs it self is extended, and yet becomes not greater than it was: as on the Contrary, when a Branch is pluckt from a Tree, the Soul of the Tree is not made less than it was. After the same manner it is in Generation. For whereas before a Plant generates the soul is but one in number, because it is but in one subject: yet now that the Plant generates seed, viz. such a matter as wherein the soul which was before in one numerical subject may now be multiplied in its existence; & that Seed being ripe is separated from the Plant: in each seed though never so smal the soul remains entire, and now it lives by its own soul and subsists by it self; and since of one Plant of Poppy more than an hundred seeds are bred, the same soul of the Poppy exists entire in each seed; and then the Soul is said to multiply it self: which when it doth, it becomes no lesser than it was; since of it self it hath no Quantity.

How the Soul multiplies it self.

But which way the soul it self remaining entire can communicate its Essence to another, this is that which hath perplexed great Wits, and not being understood hath raised many disputes and bred many Errors. For *Jul. Cæsar Scaliger* saies rightly concerning the Soul, *Exercit.* 307. *sect.* 29. *We see the shallowness of our Understandings. Who dares say he comprehends the species of substances? We cannot attain to that exquisite knowledg, how of two things one is made; how the Form is totally in the whol Body, and totally in every part. So divine a thing is the Form, that being a substance it fils another substance ful of it self, so that of both one is made. Therefore to enquire further is the part of an over curious and busie mind; for it is a part of humane Wisdome to be contentedly ignorant of some things.*

Whether the soul be divisible.

But chiefly that question hath much troubled many, whether the Soul be totally in the whol Body, and totally in every part thereof: also how the Soul is divisible, whether in regard of its extension by means of the Body. Where some hold that all the Souls of perfect Animals (and they only) are indivisible and unextended: others hold that all the souls of perfect Animals are divisible and extended, only the rational Soul of man excepted. But the Conimbricensian Collegiates do hold both these Opinions to be very probable, and therefore they answer the Arguments brought to prove both, and so leave the Reader unresolved: yet they confess they had rather maintain the former. *Fortunius Licetus*, in his two Books of the Coextension of souls with their bodies, holds that al souls, yea the rational, are co-extended with the Body.

How souls are co-extened with the Body:

Hence also another controversie hath risen, how in the Augmentation of the parts of the Bodies of Animals which grow the growing parts do receive the Soul; which is attended with exceeding great difficulties, as *Zabarella* also confesses, and is so obscure, that it moved *Sebastianus Basso* (a man otherwise quick-sighted enough in the things of nature) to deny that there is any such thing as a substantial form, and absurdly to hold that the form in a body natural is nothing but a certain collection of particles of the same kind into an excellent kind of Harmony. Now among others, *Jacobus Zabarella* hath written largely of this Question, *Lib.* 1. *de Accretione*, where having in Chap. 13. recited contrary Opinions, and rightly rejected the Opinion of *Scotus* and others, who hold that the Soul flows with the matter, and that in the parts of the matter bred of the Aliment particles of the Soul are bred, and that so just the same soul does not last during the life of the Animal; and had undertaken to defend the other Opinion, that the Soul all the Life time remains the same in number, and when new matter comes is extended to inform the same, Chap. 16. he propounds two very urgent doubts against the same: The first is, That after this manner, when the Soul which is in the old flesh passes over to inform the Flesh newly composed of Nutriment, the Form seems to go out of one subject into another, which seems to be absurd. The other is, That thus the Soul wil seem to be movable of it self; whereas *Aristotle* in the 6. *Physic.* teaches, that Bodies only are of themselves movable; and that the Soul is movable only by accident according to the motion of the Body, in 1. *de Anima*. But *Zabarella* rightly answers to the first, that the Form in this manner does not totally forsake his subject but remains therein, yet passes over to inform new matter, which transition, or diffusion wants a proper name.

And

And to the Second; That the Soul does not paſs over to inform new matter by motion, but after a certain manner to us hid and unknown. Which things although *Baſſo* does laugh at, yet if rightly explained they are moſt true. Al the Errors which many run into in this point do proceed from hence, becauſe they attribute ſuch things to the Form and Soul as belong only to the Body, viz. Quantity, Diviſibility, and parts. But that which *Scaliger* writes concerning the motion of Angels, *Exercit.* 359. *Sect.* 12. is alſo true of the Soul; that it is extended without predicamental Quantity, and moved not with corporeal motion, by paſſing from place to place, but with the motion of a thing incorporeal and extended by changing its *Ubi*. For as it is in *Exercit.* 307. *Sect.* 13. *Whatever is moved is in a place. But the Soul is not in a place, becauſe it hath no quantity. For that which hath quantity cannot be at once in al the parts of a living thing that hath quantity. But the Soul is in every part of the body which hath quantity.* And a little after; *The Soul it ſelf becomes no greater, by means whereof the body is made greater.* And therefore he himſelf cals it not motion properly ſo termed, but in the ſame place he writes: *When it is introduced into that part which is added to the body, the Soul which before was in the magnitude (for example ſake of a foot and an half, is advanced half a foot.* And a little after: *The Soul is transferred by promotion of it ſelf, from it ſelf to al that which is newly added to the body, even to the utmoſt circumference, al the matter being mean while filled which lies betwixt.* For thus when the Nature of a thing is not very cleer, neither is it eaſie to invent names, and thoſe names we uſe are equivocal, and taken from things more known.

Whether the ſoul move?

But that we may in ſome ſort explain the Nature of the Soul as far as the weakneſs of our Underſtanding wil give leave, and that we may declare how we are to underſtand what is commonly ſaid, that the Soul is a total Being, which may be divided, extended, multiplied, and that ſome light may be given to al this Doctrine of the Generation of living things, thus the caſe ſtands. All natural Bodies conſiſt of Matter and Form, which in living things is the Soul. The matter of the Body is of it ſelf ſubject to Quantity, and diviſible into parts having Quantity, and a Body ſo takes up place that it wil admit no other body thereinto, and it is movable from place to place. But the form and ſoul hath no quantity, and therefore it fils and penetrates the whol Body, it is indiviſible of it ſelf, yet is co-extended with the whol Body without quantity. But ſince (as the Schoolmen rightly teach) a thing is ſaid to be ſome where three manner of waies, either Definitively, or Repletively, or Circumſcriptively and Locally: the Body only is circumſcriptively in a place, and ſo ſaid to take up a place. For two Bodies having quantity can never be in the ſame place, and that place which one body hath taken up another cannot poſſeſs unleſs the body firſt by local mutation paſs into another. But ſubſtances free from quantity (as alſo ſenſible ſpecies) can be either divers of them together, or with other bodies in ſome place; of which we have ſpoke more largely in our 1. B. of Natural Philoſophy, chap. 5, and 6. And although the manner of exiſting any where repletively does properly belong to God, who (as *Damaſcen* writes) *is all, and totally every where, wholly in all, and wholly above all*, high, glorious, immenſe, incomparable, incomprehenſible; but Souls are not every where as God is, but are limited and contained within their own Bodies; yet learned Men (and amongſt the reſt *Johannes Faber ſtapulenſis, Dialog.* 2. *Phyſicarum Introduct.*) do attribute the manner of being ſome where repletively to the Soul alſo, and being carried aloft by the wings of their Mind from the loweſt plenitude to the higheſt and infinite, they acknowledg the Image of God who fils al things, and exiſts totally in the World, and totally without, even in Souls; and that rightly. For the Soul of al Animals fils the whol Body which it informs, nor is it hindred though the Body have filled this place before, but that it alſo can be in al the parts of the Body. And al Dimenſions being taken away, the form of any of us may be in the ſame *Ubi* with that of another, nor would the preſence of one hinder the preſence of the other. As we ſee many lights ſcattered through the ſame Air, nor does the preſence of one hinder the preſence of another; and although there are many in the ſame place, yet they are not mingled, which the ſhadows declare. Alſo we may ſee the ſame Soul which at firſt fils the Body of a ſmal Branch ſprung up from an Acorn, and of a ſmal Infant; afterward when the ſaid Branch is grown up to a tall Oak, and the Infant is become a large Man, yet it fills the ſame Bodies though it ſelf be not augmented.

The nature of the ſoul declared.

The Body hath quantity, is diviſible, takes up place, is movable.

The ſoul of it ſelf hath no quantity, fills the body, is indiviſible, is co extended with the Body.

Three manners of being any where, two bodies cannot be together in the ſame place.

What things are repletively any where.

God fils al things.

The ſoul fills the whol body.

And to apply what hath been ſaid to our preſent purpoſe; as when of a ſmal Branch a tal Tree is grown up, or of a Calf an Ox is made, of an Infant a ſtrong wel-ſet Man; the ſoul in the Tree, Ox, Man, is not made larger than when it was in the Branch, Calf, Infant: ſo the ſoul when by the ſeed it gives Eſſence to divers individual matters, it is not made leſſer,

How the ſoul can be multiplied.

nor does it lose any thing, and the soul which is in the seed born by a tall Tree, is no lesse than that which is in the Tree it self.

The soul properly is not divided: whether the soul be co-extended with the body?

By al which it appears that it is more proper to say the soul is multiplied than divided. For since nothing is divided but what hath Quantity, and one part without another, but the Soul hath no quantity, nor hath it one part without another, properly it is not divided neither by it self, nor by accident. The body indeed as having quantity and one part without or behind another, is divided, nor is the part taken from the Body of the same Essence with the whol: but that part of the soul which is separated from the Generator is of the same Essence with the soul of the Generator; and although it be in a smaller body, yet is it as totally and entirely there, as the soul of the Generator is in this Body. And that Extension may offend no man, nor cause him to think that the Soul because it is extended hath parts; let him ponder with himself how that of *Scaliger* is to be understood, *Exercit.* 359. *Sect.* 12. That the Soul is extended without predicamental quantity. Where we must distinguish betwixt extension properly so called, and extension taken only analogically. Extension properly belongs to quantity and bodies which have parts so disposed that where one is the other is not; for examples sake, where the Foot is there the Hand is not. But the Soul although it be joyned to the body, because it informs a body measured and extended, and the plenitude and replency thereof (for so the School-men term it better than Extension, and *Fortunius Licetus* might better have used this word in the Title of his Book *de Coextensione Animarum cum Corpore*) is as large as the body it self, and its dimension, and fills it though it grow never so big, no part being added thereto. Yet there is not one part of the Soul in the Eye, another in the Foot, nor is the Soul in a Man greater than that in an Infant; but as God is immense and infinite every where, not having part without part, or behind or after part: so also after its fashion the soul fils the whol body, not having part after part. Whereby we may easily answer that Objection which hath troubled many, and *Basso* amongst the rest; That if the Soul be totally in the whol Body, it wil follow that when a part of the body is cut off (as for examples sake, the Hand) the Soul wil be divided with the division of the Body. For in such things truly in which the Seminal Principle is spred al the body over, as in a Willow, the Soul is multiplied by cutting off a branch, or as they commonly speak, is divided: but in Animals where Propagation is made by Seed the soul remains intire in its body, though a part of the body be cut off; as also in growing, although the soul communicates it self to the parts added to the body, yet it does not pass out of one subject into another. *Fortunius Licetus* also acknowledged thus much, *Lib.* 2. *de animæ Coextensione, cap.* 4. where he makes a twofold extension, one material belonging to magnitude, which is only in a thing which hath corporeal quantity; the other formal and belonging to an incorporeal substance: and he rightly adds, That although these two extensions, Material and Formal, have an analogy and proportion one to another (viz. Because either of them bounds the thing defined within certain limits: for God alone is totally every where) yet herein they differ, That extension formal so called makes not the thing to which it belongs to be subject to quantity, nor necessarily divisible, either of it self, or by accident: but material extension so called makes a thing both to have quantity and divisibility. Sensible species do also afford an Image of this thing. For if a bright shining thing be in some place, or any other image of a thing, and there be only one man that sees it, or one Looking-glass to receive the Representation; the whol Image of the visible thing is in the eyes of one Man, or in one Glass. But if an hundred, or a thousand, or more men come, or a thousand Glasses be set, the same image which was before received by one Man and by one Glass, does now appear in a thousand Men, and a thousand Looking-glasses; nor yet is the Species or Representation of that visible Object divided into Quantitative parts.

A twofold extension

Every form can multiply it self:

And hence arose that famous Axiome of Philosophers; That every Form multiplies it self. Which although *Zabarella* quotes, *de sensu agente, cap.* 5. where he treats of sensible Species: yet it does not therefore follow (as one unskilfully imagines) that it is only true of accidental Forms. Contrariwise, it is rather generally and primarily true of the substantial forms, and only consequently of the accidental. For substantial forms are really forms; but accidental forms are only their Images and shadows as it were. And therefore if accidental forms have a power to multiply themselves, much more have substantial forms the same power; since accidents do al that they do by vertue of their forms. So that it is apparent that *Zabarella* understood this Axiom of substantial forms, from *Lib. de facultat. animæ, cap.* 11. where he writes, That it is the proper condition of the Vegetative Soul that the Generator should afford some of his own matter and some of his own form; and in that whol Chapter he teaches expresly, that that same vulgar Opinion of the Eduction of Forms out of the

the aptitude of the matter by the action of an external Agent hath by no means place in living things. And *Aristotle* also himself expressly teaches, 2. *de Anima, cap.* 2. *text.* 20. That some Souls do multiply themselves, when he writes that some Plants divided and separated do therefore seem to live because the Soul which is in them is actually indeed one in every Plant, but potentially many; which also he grants in some Animals. Which if it be true in Plants which live divided, why should it not be true in them also which are propagated by Seed, that so the Soul should be said to be one, but potentially many, viz. by the Seed, as wel as they can multiply themselves by the division of their body?

Many manners of the souls propagation.

Now this multiplication is performed divers waies, as shal be said hereafer. But this is common to al, that the Soul should have its proper subject wherein it might cleave, and by which it might be separated from the Generator, and might constitute a new Individual; which is the Seed, or somwhat analogical to the Seed. *All* four-footed Beasts do communicate their Souls by their seed; Birds, Serpents, and Insects some of them, do bring forth Eggs, or somwhat analogical to Eggs, and by them they multiply themselves. In Plants there is a various manner of Propagation, as shal also be said hereafter. For some propagate themselves by Seed, some by Branches, some by a Root or Bulb, and some by divers of these waies. For it is not in them as in Animals, where the Soul is tied to the seed, or to somwhat which answers the Seed, but it is diffused through the whol Plant, or through its parts, so that it can multiply it self by any part if it be put into the ground, so that thence a new Plant wil arise. Nor are the Souls nevertheless divisible in Plants although it be commonly so said; since they have not one part without another, but the body of the Plant only is divided, and is made less by cutting off some bough, branch, or Root: nor does it give part of it self to the Seed, the Branch, the Root, but its whol self, and so multiplies it self.

The soul is multiplied in its proper subject.

Here also I must explain how that is to be understood which I have written in Chap. 9. *de Consens. & Dissens. Chymicorum cum Aristot. & Galeno*, that the forms also of Metals are multiplied after their fashion; since a certain malignant Person hath charged me to hold that a stone begets a stone, and metal begets metal. For I am not so blockish and foolish as to beleeve that this Load-stone, this Diamond, this Crystal, this Gold does engender, as one Poppy breeds another, and one Lettuce another. For multiplication taken in this sence does properly belong to the living and Vegetative Soul; and Generation is the Work of a living body only. Yet this is true in the mean time, That Jewels and precious stones were not al particularly made at the first Creation, but Experience and Histories cited in the place aforesaid, do evince that the Mines and Matrixes of Jewels and Metals being once exhausted are filled again, and others succeed in the room of those that are digged up. This therefore is my Understanding, wherein I agree with *Anselmus Boetius*, and other most learned men; that as in Plants and Animals, by the soul lying hid in the seed is formed a Plant and an Animal; so also by a certain Gold-making, Silver-making, Stone-making, Crystal-making Spirit, containing the Architectonick form in it self, Stones, Jewels, and Metals are generated in the Earth; and from it according to every ones kind, figure, color, and other proper accidents are given to them; and that this Spirit diffuses it self into the exhausted Mines and Quarries of Metals and Jewels, and there generates new Metals and Jewels. But where that Spirit lies hid, and which is the seat thereof (in this darkness of Humane Minds, and the ignorance we are in concerning the Constitution of the inner parts of the Terrestrial Globe) is to us unknown. This is certain, that those Architectonick Spirits are various according to the sorts of Jewels and Metals, nor are they found in al parts of the Earth, but in some places only. And so much by the by, concerning the Generation (as it were) of Stones and Metals, I have said in this place to free my self from Slander.

Whether the forms of Metals are multiplied.

How Metals are generated.

Now the Souls and several sorts of things received their Power of multiplying themselves from the divine Benediction at the first Creation of the world, when God said, *Let the Earth bring forth the Herb seeding Seed, the Fruit Tree bearing Fruit according to its kind, wherein is its own Seed upon the Earth. And Encrease and Multiply.* For God did not only command, as *Thomas Erastus* wel writes, *de occult. med. propr. cap.* 15. that the things created should exist; but also that they should so propagate themselves as he had created them. Nor was that Command of his in vain, but very effectual. For when he commanded, he gave to each a power whereby they were able to accomplish his Command. By virtue therefore of this benediction, and help of the Seed, Souls are propagated as one Candle is lighted by another; and where ever they meet with a fit matter wherein they may subsist by themselves, such as is the body of the seed, they can transfuse themselves thereinto, and as

whence souls have power to multiply themselves

Scaliger

Scaliger saies, cloath themselves therewith, so that that part (if I may so cal it, for it is not properly a part) of the form hath the same Essence with the whol form, which is in the whol from whence it was separated, and afterwards also it begins to perform the same operations; and so the same Essence of the Soul which is in a tall Walnut Tree is in the Nut and that Sprout which arises from the Nut, and afterwards also having obtained fitting matter whereby to augment it self it performs the same operations, produces every year new Branches, and ingenders Nuts. And thus out of the first Individuals of all four-footed Beasts, creeping things, Birds, Fishes, Plants, Animals, at first created, the sorts and kinds have been since continued, and all Beasts, Creeping things, Birds, Fishes, Plants, have been generated by multiplication of their Souls.

Chap. 7. *Arguments to the contrary Answered.*

AND although this is a plain case, so that a Mind not prepossessed with Opinions may easily perceive the truth: yet as commonly happens in this darkness of humane Minds, some are of another Mind, whose Opinions and Arguments to the contrary come now to be examined.

The first thing which hath troubled many so as they could not see the truth, is, that neither in the seeds of Plants, nor in Eggs, nor in an imperfect Conception, those operations are to be seen which are performed by perfect Plants and Animals. But they themselves are not ignorant that the first and second act do differ, nor does an Argument hold from denial of the second act to a denial of the first act. For the Essence of the Soul is in the Seed by the first act, nor can it be proved by any reason that it should afterward receive the same from elsewhere: only the second act is wanting to the Seed since it wants only expres Instruments necessary to perform its operations, which nevertheless it hath a power to prepare. And so the Seed wants only that perfection which belongs to the Body and the structure of its parts, but not that which belongs unto the Soul. Nor can we argue in perfect Plants from the negation of the second act, to the negation of the first, as may be seen in Trees and other Plants which last all the Winter, in which there is no manifest operation: and yet the Soul is really present in them.

The Soul is two waies in the Body

Again, Those actions which proceed from the Soul are twofold, Organical or Second, which are performed in a perfect Body, and Prime or Inorganical, viz, the Vegetation of the Seed, the Formation of the Body, with its nutrition and augmentation. For as soon as the Body begins to be formed, it begins to be nourished. And although the Seed in the Corn-loft be not nourished, yet it hath a Vegetative and Nutritive faculty: after the same manner as Plants pluckt up are likewise not nourished, yet are really animated, and being transplanted into another soil they are again nourished.

The force of Nature, whence it is.

Another thing which troubles *Galen*, is, that the Vegetative faculty being void of Wisdom and reason seems unable to perform so wonderful a work, wherein the greatest Art and wisdom appears, and which cannot be done but by a most wise and powerful Artist. But no man wil wonder at this who knows that the Soul is the Principle and immediate cause of these operations, but yet that it hath not its power from it self, but hath received the same from the most wise and powerful Creator; whence also *Scaliger Exercitat.* 188. & 359. *sect.* 11. defines Nature to be the ordinary power of God, and in *Theophrast. de Causis Plant. cap.* 1. the power of God in the second causes, to which himself hath prescribed certain rules to act by. For as *Thomas Erastus* writes, *de occult. med. propriet. cap.* 15. Nature is nothing but that same command of God by which all things are what they are, and perform that which they are commanded. For God did not only command them to exist, but also to propagate themselves as they were created by him. And what reason hath *Galen* to admire that so wonderful things are done by the formative Faculty, since he might have observed things as strange in the Elements themselves? The Elements are moved in a straight perpendicular Line, upwards and downwards, although they know not what a perpendicular Line is, because God hath commanded them so to do.

What Nature is.

Whether the soul cannot be but in an organical Body.

A third thing which hath moved many is this; That they conceive nothing can be the subject of the Soul but an Organical Body, [being moved thereto by *Aristotle's* definition, who defines the soul to be the act of an Organical body. But *Aristotle* did not define the soul simply considered in its Essence, but in order and respect to the Body. Which nevertheless, since it finds not, but forms and shapes it for it self, it must needs at first be in an inorganical Body.]

Body.] But that an organical Body is not necessary to receive the Soul into, many things do shew. For in the first place, since to an organical constitution is required a certain Quantity, Number, Figure and scituation of parts; all these things are not necessary for the reception of Forms. For Forms (such as souls are) having of themselves no quantity, are received into matter without Quantity or Figure. And this we see manifestly in Plants, in which the Quantity and Figure are variously changed the same soul remaining. For the Quantity and Form of a Branch springing up from a Seed is one, and of the same grown to a tall Tree, another. The stalks of many die in the Winter, the Root remaining alive, and in it the Soul. Again, the figure of bodies is an Effect of the Forms and Souls. And therefore it is not a previous disposition foregoing them. For the Form it self is that which determines the Quantity of its own body, and each Soul brings in a determinate Figure into its own Body, and preserves the same in Nutrition and Augmentation; hence there are so many figures and magnitudes of living bodies as there are differences of souls, and a Rose hath one magnitude and figure, an Oak another, a Fir Tree another; a Partrich hath one, an Hen another, a Peacock another. Thirdly, the Soul is of it self and primarily in the parts as they are similar, and not as they are organical. But the similar parts as such have no certain figure: and therefore the soul is not in them as they have a certain figure, or quantity, but only as they are such similar parts. And it is in the organical parts, only as they consist of similar parts. So that the Soul is not in the Bone, as it is a Tooth, a Shank, an Arm-bone, or an Ankle-bone, but only as it is a Bone, and it is equally in all Bones. And therefore in fractures in which the Bones have many times another figure than naturally they should have the Soul remains nevertheless, and is as much in a great *Callus* as it was before in the sound Bone. And therefore in Nutrition it is brought into the aliment which hath no figure; and it suffices that it hath this or that temperament and similary Constitution. And so the organical disposition is not necessary for the first act, but only for the second act, or to perform the operations. Nor is the body as it is organical simply the adequate subject of the Soul; but then only an organical body when the body is now perfect, and ought to operate, and by its operations to preserve it self alive. And the Organs are required for operation and not to simple being; and then only are necessary to being when the being cannot be preserved without operations; which happens when the Body is already brought to a perfect state. But the figure and organization (as some speak) is after the Soul and not before it; and therefore it is not a disposition necessary to the reception of the Soul. Moreover the dispositions to the form are immutable: but the figure and organization in living things are not immutable. Both is apparent in Animals and Plants. The fortieth day is the longest term set by those that hold the Soul is infused. But then the parts are only rudely delineated. And what shal be said of bruits whose Souls none hold to be infused? Is not the Soul there presently on the first daies of the Conception? And this happens much more in Plants. For in the first daies when Plants begin to shoot and sprout out of their seeds the shape of the Plant is yet so rude that it cannot be known (save by most skilful Herbarists) to be this or that Plant, which afterwards in process of time is many waies changed.

The Form determines the Quantities and Figures.

The Soul is in the parts as they are similar.

Nor is that of any moment which *Sanctacruzius* objects here; since Souls are more noble than the forms of Elements and Bodies simply mixed, they require also a noble configuration and formation, and by how much living things are more noble, by so much the more noble body they require, and hence the so many sundry figures of Plants and Animals have their original. True it is indeed, that all living things by reason of the divers operations they are to perform do require divers organs; and therefore Plants have one manner of shape, Animals another, and every sort is differently figured according to the nobility of the forms. But it does not from thence follow, that those figures are required for the fabrick of the organs, before the introduction of the Soul, and that they are a disposition necessarily foregoing the Introduction of the Soul; because (as hath been said) that same formation of all the Organs is not necessary to simple being, but only for the better being and performance of operations. And if those that contend so eagerly that the body must be organized before the soul can come into it did but observe such things as dayly happen in Nature they would think far otherwise. *Fortunius Licetus* the most renowned professor at *Padua* hath taught sufficiently, *de spont. Vivent. Ortu*, that the soul may remain safe and sure in a matter far more vile and ignoble than any seed can be thought to be, although it be destitute of such things as are requisite to its second Act; which at last having attained a fitting matter does rouze it self up and becomes a Plant or Animal. Of which I shal speak hereafter in *my Discourse of the spontaneous original of living things.*

Fifly,

Fifthly, Some do also use this Argument, which is also the fift Argument of *Thomas Fienus*, *quæst. 6. de format. fœtus*, which *Alphonzus a Caranza*, a Spanish Lawyer, does so highly esteem, in *tract. de partu naturali & legitimo*, *cap. 1. pag. 44.* that he cals it a singular and irreprehensible Argument, and which quite overthrows the contrary Opinion, and therefore he thinks fit to set it down word for word; whose words I wil also transcribe intire, that the Reader may see whether the force of this Argument be so great as *Caranza* imagines. Now thus saies *Fienus*. If in the seed there were an active Principle of Conformation or Generation (as others confound them) the seed should act upon it self; but nothing acts upon it self, as *Aristotle* teaches, *1. de Generat. & Corrupt. cap. 7. Ergo.* Because if any thing should act upon it self, the same thing should be Agent and Patient, in act and power in respect of the same; which is impossible. Secondly, because it would be destructive to it self, especially the seed: because that action thereof should tend of it self to its destruction. For it would tend to the Generation of a living thing, which cannot be done without the destruction of the seed. *Scotus* in *2. sentent. distinct. 18. in fine*, after he had said that the seed is not the active principle of the last form, viz. the rational soul, he enquires whether it can be the previous alterative Principle of an Organical body which is generated; and he concludes that it cannot, and brings this reason among others; because (saies he) this absurdity would follow, that somwhat should act upon it self: which argument he counted so strong, that he said, to find the principle of Conformation we must be forced to fly to the Action of God, and of the Heavens. To answer this argument it is commonly said that in the seed there are two divers substances; the one thin and spirituous, the other gross and terrestrial. That in the former resides the Activity, and the latter is the matter and passive principle; and that the active vertue out of the spirituous part does act upon the thicker part of the seed as upon matter; and that for this reason one and the same thing does not act upon it self, but on a different subject; nor that one and the same thing hath the notion of an active and passive principle in respect of one and the same thing, but only in respect of divers things; which is not absurd. That that same active principle or vertue does reside in the seed, *Aristotle* teaches in *2. de Generat. cap. 3.* in these words: *There is in the seed that which makes it to be fruitful*, viz. *That which is called Heat; and that not fire, nor any such faculty, but a spirit which is contained in the froathy body of the seed, and that nature which is in the seed having affinity with the Element of the Stars.* *Thomas Aquinas* teaches the self same thing, *1. Parte, quæst. 118. art. 4.* in these words: *And therefore there is no need that that same active faculty should have any organ in act, but that it be founded in the spirit it self inclosed in the seed, which is froathy, as the whiteness thereof shews.* And the very same he saies, *2. contra gentes, cap. 89.* and in some other places. But this Answer is not worth a button, and in very truth, is no other than a meer evasion invented to shun the force of the argument. Because it is not true that such a vertue resides in the spirit of the seed. Which is proved first, because the spirit which is in the seed is either an essential part thereof, or it is not. If it be, it wil follow that one essential part of a being is destructive to the other essential part of the said being. This cannot be, first because infinite things are found in the World consisting of divers and heterogeneal parts, in which nevertheless we never find that the one destroyes the other. For if one were ordained to destroy the other, it would follow that it were ordained for the destruction of the whol, and consequently of it self. For one essential part of a thing being destroyed the whol thing is destroyed. But the contrary is true; because the essential parts of one Being are not made to fight one against another, or to destroy one another, but that they may be friendly united, and by their friendly union be able to sustain the form; and the form again is ordained to hold those parts united, and to govern them, that they may not part asunder, nor mutually destroy each other. For if it were not so, the form could never persist and abide in things heterogeneal, no not the smallest time imaginable. Add hereunto, that all action proceeds from a total being, and a perfect being; but the essential parts of one being are not the whol being, nor a perfect being; and consequently they act not by themselves. So far *Fienus*.

Whether the seed acts upon it self?

The soul is the first Agent in the seed.

Two parts in the seed.

But this Argument is not so strong as *Caranza* doth imagine. For in the first place we must know, that to speak properly the seed is not the cause of Conformation, but the soul in the seed. And so when a living body is formed out of seed, the same thing does not act upon it self. For there are in the seed two parts; the soul and the body of the seed. Now the first Agent is the soul, which does not act upon it self, but upon the subject matter, viz. the body of the seed, and also upon the Mothers blood, which in Animals it draws to form the yong one, and in Plants upon that Aliment which it draws out of the Earth. And although

though when a Plant or Animal is generated the seed ceases to be: yet that Generation is no corruption but perfection, and that body which is called Seed whiles it turns to a Plant or Animal it is brought into a more noble state and perfected; nor (as *Jul. Cæs. Scaliger* speaks, *Exercitat.* 268.) is the Seed otherwise said to be corrupted than that it ceases to be as it was before, viz. in aptitude, and becomes as it was not, viz. in act. Now it is the same matter with the same formal Principle, to which nothing else is added than the expression of the Organs which were before confused. And thus while of the Seed is made a Plant or Animal, the Body of the Seed does not transfer it self into another condition, but by the Soul lying hid therein it is thereto advanced. Nor (as *Fienus* thinks) will he that shal diligently weigh al these things use that answer which *Fienus* brings and endeavors to refute, that there are two divers substances in the Seed, the one thin and spirituous, the other gross and earthy; and in the former resides the active vertue, the latter being the matter and passive principle. Such a spirit there is indeed in Seed, but it is not the primary cause of conformation, but the Instrumental; but the Soul which uses that spirit is the primary cause. And whereas he dares deny that there is a spirit in the seed, I can scarce sufficiently admire it, and the reasons whereby he would prove it are very sleight. For in the first place that spirit which is in the seed as an Essential part tends not to the destruction but to the perfection thereof. Also it is false that every action proceeds from a total being. For is there no action of the soul upon the body which it informs? And whereas he denies there is a spirit in the seeds of other living things, we shal refute that hereafter.

whether the Efficient Cause be alwaies external?

Fiftly, This also offends some that they suppose that thus the distinction is taken away betwixt the internal and external Causes: of which the former are the matter and form, the latter the Efficient and End: and they aver that no Efficient Cause does ever go into the Essence of the Effect, and that Animals in Generation do not produce seed either out of their own matter, or out of their own form; but that the seed is generated of the mixture of blood and spirit in the stones, and that a man does not generate by communication of his Essence, but by his form as an Efficient Cause. But in very deed, this Doctrine of the propagation of Souls does no waies take away the distinction of Causes. For it is known even to Novices in Philosophy, that the same Essence may be both the Form and the Efficient Cause, the Form as it informs the Matter, the Efficient as it is the cause of al Operations performed in the compouud. The rest are but Beggings of the Question, and are said, not proved. I like *Zabarella*'s Opinion better, who writes, *de facultat. animæ, cap.* 11. *That living things when they generate their like do confer and bestow some of their matter, and some of their form, inasmuch as they confer an animated seed, and endued with the same vital faculty which was in the Generator.* For although they communicate no part of their own body, yet they communicate that self same matter of which they are nourished, but changed into a more noble substance. But that which hath brought very many into this Error is this, Because they conceit living things are generated after the same manner as artificial things are produced by an external Agent. But there is a great difference betwixt Artificial and Natural things. For every Artificer communicates nothing of his own: but living things which beget their like cannot do the same unless they communicate their own Essence.

The difference betwixt Nature and an Artificer.

whether the soul goes out of one subject into another.

Sixtly, Neither is that of any moment that they suppose if Generation should be made by transmission of the soul, that then the soul should pass into another matter as a new subject, or should be of it self divisible. For as in Augmentation, and when of an Acorn a tal Oak grows up, the Soul when it communicates it self to new matter does not pass from one subject to another, but remaining stil the same communicates it self to new matter: so when the soul communicates it self to the seed it does not pass from one subject to another, but remaining the same in the Generator it diffuses it self into the seed. Nor is it therefore of it self divisible. For as when a root or branch is pluckt from a Plant, of which (being set in the ground) a new Plant arises, the soul of the former Plant is not diminished, but remains entirely the same: so also when a soul is communicated by the Generator to the seed, the soul of the Generator is not made lesser, but remains the same it was. Nor is there here any difference betwixt the Root and the branch pluckt from the Plant and the Seed. For there are several waies of propagating Plants. And that the root and branch is animated, but not the seed, is only said, but not proved. For though the Seed be not a part as the root and branch is; yet it is the fruit of the Plant which is animated as much as the parts are, yea, and contains the soul after a more excellent manner.

The soul is not divisible.

Seventhly, Many do also object this, That if the seed of the Plant were animated it should be already essentially a Plant. But if it were essentially a Plant when it grows out

whether the seed be a Plant?

of the ground, there would be no Generation of a Plant, and so in the Tree and that Herb in which the Seed was produced there should be a generation, and a Tree or Herb should be generated in a Tree or Herb, and not in the Earth; which is absurd. But the whol argument is granted in its sense, and that which is counted absurd is no waies absurd indeed, provided it be rightly explained. For truly the generation of the seed in a living thing does not finish the Generation; howbeit the principal and chief work which is necessary to Generation is the Elaboration of the seminal matter that it may be a fit subject wherewith the soul may be propagated, and the communication of the Soul to the matter so elaborated. Howbeit this also afterward belongs to Generation, that the seed which hath received the Soul from the Generator may no longer adhere to the Generator, but may be separated therefrom, and that that which before was but one individual of the same kind may now become more than one. Which when it is performed a Tree or Herb is truly said to generate, but not when the Plant grows up out of the Earth. And when a Plant shoots up out of the Earth that is not its generation, but it is the bringing of a Plant which is in its imperfect act to its perfect act. Nor is it considerable, as *Fienus* himself writes, *quæst.* 5. *concluf.* 6. (though he be otherwise of a contrary Opinion in this Question) what the common People cal Generation, or what not; nor what agrees with their understanding, but what is suitable to right reason and to truth. For the common people are ignorant of Philosophy, and know not when or where the true production of a Plant is made, and its Essential Generation; and know not how to distinguish betwixt the first and the second act; betwixt that which is imperfect and that which is perfect, and therefore takes one for another, and conceits that a Plant is then generated when it is perfected and operates, and when it brings forth roots and Leaves, whose production is not the very Generation of the Plant, but the operation and perfection thereof being already generated. And *Aristotle* himself calls the seed and that out of which it is bred, *Synonyma's*; We must therefore distinguish betwixt the Entitive and Formal Act, and that which is simply Formal, and respectively. For then is the Form said to be present in a perfect act when it hath al its Organs necessary to perform its actions, but not when it is in a part, or in the matter of the seed, and that not yet fitted with al its Organs. For otherwise the branch of a Fir-tree (in which it cannot be denied that the soul is) should be called a Fir-tree; and the Foot of a Man should be called a Man. And therefore we cannot argue from the presence of the Form to the denomination of the thing formed, but then a thing is rightly said to be an Animal or other living body when the soul is in its subject rightly disposed, or can perform the Operations belonging to its kind.

what things are required to generation.

when Generation is made.

How many waies the form is in a thing.

whether the seed be an Animal

Eightly, Out of which their Objection may easily be answered, who say, If the seed were actually animated, the seed of a Poppy were a Poppy, and the seed of a Dog would be a Dog. For the sorts of Natural things are not denominated from the Essence which the Form gives, but from that Constitution whereby they are sensible species of the World. And therefore though in respect of the Form the Essence of a Dog and of the seed of a Dog is one and the same; yet since the Constitution of the seed and the Dog differ in respect of the Corporeal and sensible parts, the seed is not called a Dog, but the seed of a Dog. After the same manner though there be one and the same Soul in the Butter-fly and the Silk-worm, yet the Silkworm is not called a Butter-fly till it hath wings and can flie.

whether the seed lives?

How many waies life is taken?

Ninthly, They say, if the seed were animated it should live, if it lived it would grow, for every living thing is nourished as long as it lives, as *Aristotle* testifies *de Respirat. cap. ult.* But because seeds lying in Corn-lofts and granaries, or shut up in Chests and Boxes are not nourished, therefore they do not live, and consequently they have no soul in them. But life is taken two manner of waies, either for the first act, or the essence it self of living things, or for the second act or operation. Seeds live by the first act, but not necessarily by the second act, nor do they necessarily perform the actions of living things. And that place of *Aristotle* is only to be understood of living things perfectly formed. But in the mean while the soul in the seed is not quite idle, but it keeps the seed alive, and therefore seeds are so long fruitful as they retain the soul in them: but after they have lost the soul they become dead and unfruitful. Nor are the Operations of the Soul confined to nutrition only, but there are also other Operations thereof, as Conformation. Yet as soon as any Conformation is made, and as soon as the seed hath attained a fit place and matter, the soul presently draws nourishment for the formation and nutrition of its body.

And thus I conceive it is proved in general, That the soul is in the seed, and that it is the Cause of the Conformation of the Body animate, and I conceive al Objections are fully answered.

swered. Howbeit some when they can hardly object any solid reason against our Opinion do fly to the Authority of *Aristotle*, but miss-understood, and they say that *Aristotle* writes that the seed is potentially animated, and that therefore there is not actually any soul in the seed. But here the most renowned *Casparus Hofmannus* rightly answers, *tract. de origine formarum*, that *Aristotle* does so often attribute an act to the seed, that it is the part of a man very unskilful to urge only those places wherein he saies it is an aptitude. Howbeit, more Reasons shal be produced in the following Chapters, wherein we shal treat particularly of the generation of living things, viz. Plants and Animals: and what hath hitherto been alleadged shal be explained and confirmed, and such objections as may yet be made shal be answered.

Whether the seed be potentially animated?

See also of this Subject the lately commended Doctor *Caspar Hofmannus*, who in *tract. de form. origin.* joyned to his Books of the Generation of Man, proves the same Opinion by most firm reasons, and solidly refutes the contrary Opinion of *Bonamicus*, the Conimbricensian Collegiates, *Peter Fonseca*, *Franc. Suarez*, *Ant. Ruvio*, *Benedictus Pererius*, *Franciscus Vicomercatus*, *Fredericus Pendasius*. And in good deed the judgment which he makes of the Conimbricensian Collegiates is most true of al those who defend the Eduction of the Soul out of the aptitude of the matter, and deny that seeds are actually animated. Not to say (quoth he) that they mix many things not belonging to Natural Philosophy, they invent distinctions little less than foolish, they put conditions where they ought not to be, the greatest difficulties they touch not so much as with their little finger: in a word, they intangle and obscure, but do not explain the Question.

But the Soul frequently uses the Spirit (in its shaping the Body) which is in the seed, and makes it to be fruitful, and resembles the Element of the Stars, as *Aristotle* tels us, 2. *de generat. cap.* 3. And as long as that spirit is in the Seeds, so long the soul is as it were in its proper subject: but as soon as that spirit vanishes, the Soul can abide no longer in the seed, and the seed becomes unfruitful. Which spirit I admire that *Fienus* could not discern. Certainly if he had seen a spirit drawn by Chymical distillation out of dry seeds which wil take flame, he would not have written, *de format. mat. quæst.* 6. what spirituous substance can there be in the seeds of Plants, kept a long time in a Box, and dry, but yet fruitful?

The soul uses the spirit when it shapes the body.

Whether there be a spirit in the seeds of Plants.

He indeed objects in *Apolog. Adversus Sanctacruzium*, *pag.* 99. If there are (quoth he) Spirits in Plants, in what place are they generated? For there ought, as in Animals, so in Plants some place be assigned, in which they spring, and from which they flow into the Plant. Again, he saies; there is no actual Heat. But in Plants there seems to be no actual Hear. For if there were it would be perceived some way or other. For a tangible quality is the proper object of the sense of feeling. Therefore where it is it must needs be perceived. How comes it therefore that in a great heap of Herbs, and a great heap of Seeds, Corn, Pulse, there is not at least some smal heat perceived? Thirdly, heat and cold are contrary qualities, and mutually destroy one another, and the greater and more intense does overcome and corrupt the lesser; how can it therefore be that this heat in so many Plants which last all the Winter, should not be extinguished. For the Heat of infinite living Creatures being much greater, is extinguished by the Winter cold, and why should not that of Plants be extinguished if they have any?

But these are toies unworthy so famous a man. For, first there needs no place nor cavity in Plants for this spirit to breed in as there is in Animals: for as they have not any thing answering to the stomach or Liver of Animals, wherein their nutriment is bred, but that nutritive power is spred through their whol body: even so that spirit is bred in the whol body of the Plant. And if any man shal hold, that in the root or trunk rather, as the nutriment so the spirit also is chiefly elaborated, he wil hold nothing that is absurd. And that there is such a part in Plants that are tender is manifest, as in the Colewort and many more. For although the cold and frost do so hurt the Leaves that they die: yet if that part which is in the middle, which the Germans cal the Heart, remain safe and sound, the Plant recollects it self and grows again. But if that part be also hurt the whol Plant dies. For although (as *Fienus* objects) branches cut from the Tree do grow; yet that makes not against our Assertion. For as those souls according to the division of their subject, are in some sort divisible; so also the spirits are which make the proper subject of the Soul.

Secondly, That also is of no moment which he saies: where there is no Heat, there is no Spirit; and where Heat is it must needs be felt. Is there not I pray you Heat in the Spirit of Wine? and is it actually felt? Is there not fire in all mixt bodies? and yet are they al actually hot? by no means. For as *Zabarella* rightly teaches, *Lib. 2. de mist. generat.*

rat. & Interit. the Qualities in mixt bodies are after a sort hidden by the tempering of contraries, so that neither of them can be distinctly discerned. Nor is that objection of any force if it be not felt in one Plant, it ought to be felt in a great Heap of Plants. For the Nature and proportion of mixture is one and the same in a great Heap of Plants as it is in one Plant. But hath *Fienus* never seen what an Heat is raised when such an heap of Plants comes to putrifie, or when an heap of Corn begins to sprout? Certainly in Granaries even in the coldest time of Winter, heaps of Corn which have lain long unstirred do conceive no smal Heat, which a man may feel with his Hand. Yea and the Corn it self if it lie long unstirred does sprout.

Thirdly, That this same Spirit and Heat in some Plants (for all do not outlast the Winters cold) is extinguished, comes from the nature of mixture. For there is a several mixture in several Animals and in several Plants. Geese go bare-foot in the cold Ice which men cannot do. Rosemary is hurt with a smal cold, but so is not the Fir-tree. But I easily agree with *Fienus* that some hidden Quality of kin to the Element of the Stars does concur.

Chap. 8. *Of the Generation and Propagation of Plants.*

And so much may suffice to be said of the Original of Souls in General: and it hath been sufficiently declared that all living things do multiply themselves by their seeds, and that in the seed is the Soul which is is transfused from the Generator into the thing generated. For the clearer manifestation whereof I think it best to declare the same particularly with reference to the several kinds of live things. Now there are two kinds of live things, Plants and Animals, or living creatures: which have also a different way of propagation. For there is in some living Creatures sexes, in others not. In such as have no sexes one seed is sufficient, which is a body so elaborate and disposed by the Generator, that when it is perfect it may be seperated from the Generator, subsist intire by it self, and with it the soul of the Generator may be transferred into the thing generated. And then a Tree ingenders as (*Scaliger* saies, *Exercit.* 6. *sect.* 10.) when it produces seed. And that this seed is animated, appears from the reasons propounded in the foregoing Chapter; and it is so manifest, that *Joh. Gallego de la serna* a Spaniard, was forced to grant that the seeds of Plants were animated, *de Princip. Generat. Lib.* 2. *cap.* 6. (although he denies that the seeds of Animals are animated) and writes that this opinion is so founded upon the most firm reasons of Philosophy, that they being understood no true Philosopher can deny the same. And the reasons are indeed most strong whereby it is proved that the seed of Plants is animated. For in the first place since when the seed was in the Plants it was animated as being a part of the Plant, surely when it is separated it must be animated; since no cause can be assigned which drove out the soul, nor can separation alone do that, for even in the separated seed also the actions of a soul appear, and therefore as Branches, Roots, Buds, Bulbs, by avulsion do not lose their soul, but grow and flourish: it is also so ordered that the seed being separated from the Generator can subsist intire and fresh, although some seed a longer, other some a shorter while, which other parts pluckt from Plants do not commonly do, but presently die. Moreover as soon as by the Heat of the Sun, yea and of the Fire in the Winter time, it is but warmed in a stove, and finds fit matter, or but a little Water if it be moistened therewith as is seen in the making of Malt, it begins to display it self, and first thrusts out a Root, by which afterwards it draws nourishment, and forms the body of a Plant like that it came from: which formation of the bodies of Plants is no less wonderful than the Generation of Animals. For so it attracts matter fit for every part, Roots, Flowers, Fruits, and gives all parts their Magnitude, Figure, Scituation, Colour, in a certain measured proportion, that no Geometrician or Painter can imitate its workmanship. Moreover, since we see that Plants not only by their Roots, but also by a smal Branch of a Willow, a bit of an Hop or Acorns Root cut off do grow up into a like Plant, the Soul being pluckt away with the part; and it is manifest that of a branch of a Willow or a Vine, or of another Tree, although in it there is no Root, nor all the parts of a Plant, yea of a Leafe only of an Indian Fig-tree an whol entire Plant is formed; and no other cause can be assigned of the formation of this new Plant than the soul pluckt away from the former Plant with a part thereof: why should we not conclude that a Plant is formed of the seed after the same manner? Nor is it credible that al the other productions of Plants are made by the communication of the soul from the former Plant and

How many kinds of live things

The seed of Plants is animated.

The wonderful Generation of Plants.

and only that made by the seed should be performed without the presence of the soul in the seed. But more likely it is that as when Roots, Bulbs, Branches, Boughs are put in the Earth they do not from thence receive their soul, but that with the soul which they actually had they perfect themselves by producing necessary parts and organs: that in the same manner also it is in seed. Nay we have more reason to think that this should happen in seed, because it is generated by the Plant to this very Intent, and hath a much more perfect disposition necessary for the conservation of the soul and its propagation than the Roots or Branches; since the wonderful artifice of Nature is apparent in many seeds. There is indeed one man who conceives that this does not declare the manner of the souls propagation, for this reason, because in Growing whatever grows on the Plant is a part of its body, and the part ought to have the same soul that the whol hath: but the seed is no part of the body nor grows fast to the same. But although it cannot be denied that the seed of a Plant since it is not generated to that end to abide upon the Plant, nor does alwaies stick to the same, but may be separated therefrom, is not after the same manner a part of the Plant: yet because while it is in the Plant it lives by the common soul of the Plant, in that sence also it may be called a part of the Plant. But since it is made to be separated therefrom, it may most conveniently (as was said in *Cap.*6.) be termed the fruit. Which is equally animated with, yea and after a more noble manner than the parts, viz. inasmuch as thereby the soul may be propagated, which in Animals by the parts it cannot be. Sure it is in the mean while, that as when the Soul is diffused into new matter it becomes neither greater nor lesser: so also when the soul is propagated with the Seed; the soul of the Parent is not diminished thereby.

Sundry manners of the propagation of Plants.

For here it is to be noted, That there is not one and the same manner of propagation in Plants; which being observed that may easily be cleared which hath scrupled some, and among the rest also *Franciscus Vallesius*, *de sacra Philosoph*, *cap.* 1. how that should be true which we find written in *Genesis* 1. verse 11. that God commanded that the Earth should bring forth Herbs or Plants, having Seed in themselves according to their kind; when as the Willow, Fern, and very many Plants besides, do bear no seed. For the seminal nature in Plants is not one and the same, nor does it confine the seed to Fruits and Cods only; but this happens to some alone; but in others the seminal Vertue is adherent in other parts, somtimes in one, somtimes in more, and somtimes in different parts. For examples sake, Poppy is propagated only by its seed, not by its root, stalk, or leaf. And so it is with Lettuce and very many more. Rosemary is propagated both by seed and branch, and so are Pear-trees and Apple-trees; the Hop by its root; the Indian Fig-tree by its leaf; Onions and most bulbed Plants by root and seed both; such as bear buds, goslings, or palms, are propagated by their branches, as the Vine, Willow, and others. Also some have their seminal vertue in the tears or liquor which drops from them. For as the souls are more or less noble; so for the multiplication of themselves they require a more or less noble matter wherein to propagate their seminal vertue. And hence it comes to pass that Mushroms or Toadstools being the most ignoble of al Plants are propagated only by pouring their decoction about the Roots of Trees. Yea, the seminal matter of Plants may be transferred in inundations of Water, and in Rains, as *Theophrastus*, *Lib.* 1. *de Causis plant. cap.* 5. relates, how by reason of a certain thick shower of Rain, *Laserpitium* sprung up in *Apturea*, whereas it had never grown in that part of the World before; and that there a great Wood hath grown up where there never was any before. So that it may rightly be said of such things which are beleeved to spring out of the Earth of their own accord, that the nature seminal rather lies hid than is not, as shal be said hereafter when we handle the Original of things which spring of themselves. Nor am I inclined to say with *Vallesius*, that there are either Animals or Plants, which though at the first they were not created, yet they might afterwards grow naturally from the Elements of the World. For the Elements of the World have no vertue to produce such a seed. Nor let any man attribute this Formation of Plants to the Suns Heat. For this Formation is not only made when a Plant is cherished by the Heat of the Sun, but by the Heat of the Fire also. And it belongs to the Form and not to the Sun to determine Quantities. For Nature uses Heat as a Minister or Instrument, not as a Law-giver or Work-master. Otherwise in al Plants that same Quantity would be produced, and the same figure. For the Sun is the same to al; and the store-house of Mother Earth is the same; and the contrary is seen to happen, as *Julius Cæsar Scaliger* writes in 1. *de Plantis*.

Plants propagated by Inundations of water, and by rains.

The formation of Plants not caused by the Sun.

Nor

Nor let that trouble any man in this place which *Thomas Fienus* alleadges *de format. fœt. quest. 5.* as also was said before, that a Plant is produced after one manner from a Root, a Branch, or Leaf, and after another manner from the seed. That out of the former a new Plant is not produced, but they themselves when cut off from the Plant are new Plants, because by the cutting from the whol, they have already the vegetative soul multiplied by division, but that the contrary happens in seed. For that the seed is not a new plant, because it hath no soul, but it becomes a new Plant by the souls coming into it after it is planted in the Earth. But here is no diversity of propagation; for the Root, the Branch, the Leaf, is not an entire Plant, and after the same manner as by the cuttting off of these from the Plant, the soul is multiplied by division; so also by the Generation and emission of seed the soul is multiplied. And whereas he grants the Soul is in the Root, the Branch, the Leaf, and denies it to be in the Seed, he does it without Reason. For since in it the same Operations appear as in those; why should we not grant the soul to be as wel in it? And if in the Seed cast into the Earth there is no Soul, whence I pray you is it afterward produced therein, and whence communicated? Also that is false which he writes; That the Soul which is in the Branch or the Root planted, is the same numerically with that which is in the Tree, or whol Plant. Indeed it was the same in number while the root or branch was on the Tree; but after it was cut from the Tree it began to exist by it self; and was made different in number from that in the Tree. I wonder also that *Fienus* should deny the Seed of Plants to be animated, since nevertheless in the Chapter foregoing, *quæst. 5. Concluf. 6.* he expressly holds that the Conformation of the Seed in the Earth is not an essential Generation, but only the perfection of a new Plant already constituted and generated in the Tree. For there is no other Generation of a Plant in the Tree, save when seed is generated.

The wonderful multiplication of Plants.

But concerning the Seed of Plants, two things are here to be observed: the first is, That that same multiplication whereby the Soul diffuses it self into the new Plant, is most of all manifest in Plants, and almost infinite. Not to speak of Poppy, Turky Wheat, and very many others; Tobacco does so multiply it self, that he who first by numbring, and then by weighing (for it were an endless labor to number al the seeds) wil take a scantling and compute the number of the seeds, he shal find that of one Seed more than three hundred thousand seeds do spring; and if the product of these be sown the third year, he shal find an encrease of an hundred thousand Myriads (a myriad containing ten thousand.) So powerful was that Divine Benediction; *Encrease and multiply.*

Two parts of the seed in Plants.

Moreover, This also is to be noted touching the seed of Plants, That in them as in al seeds there are two parts; the one primary and which is only worthy of the name of seed; and another which serves only as a covering. The former consists of the Soul, which is the Author of the life and formation of a Plant, and the matter, of which the first rudiments of the Plant, viz. the Root and the first Sprouts are constituted. For the Seeds of Plants in whatever place moistened and cherished with heat, even without the Earth, do first gape and thrust out their roots, and afterwards their first sproutings: but the body of the perfect Plant cannot be entirely formed, unless aliment be drawn from the Earth by the first smal roots. And so in these there is not the same Agent and Patient, but the Soul is the Cause of Formation, I say the Efficient and Agent Cause, and the Matter is the Patient on which it works. But that which in Plants is properly the Seed, and hath the soul and matter out of which the first Rudiments of the Plants are framed is only that pulp which contains in it the Idea and delineation of the whol Plant. And indeed the whol pulp of the Seed is not animated, but only that part thereof which is commonly called *Corculum.* Which part if it be corrupted, the seed wil not grow. And therefore the Pismires are reported to gnaw that part of the seed that when it is by them hoorded up it may not sprout. Contrariwise, although the rest of the Body be gnawn by worms, yet it grows, provided the Heart be safe, as we see in Beans and Pease, and French-beans. But the rest and greatest part of the Pulp is not made in vain, but is in place of Nutriment as it were for the tender Plant which is immediately produced of the seed most properly so called, as is easie to see in French Beans, which being set in the ground, when they begin to shoot one part goes downwards and makes a root, the other goes upward and makes the rest of the Body of the Plant. On one side of this tender Plant lies the rest of the body of the seed, out of which a channel or pipe of Conveyance goes into the tender Plant, by which alimentary juyce is carried thereinto, until it grows up and gets strength of it self to draw alimentary juyce out of the Earth to it self, and to elaborate the same. In respect therefore of the pulp of seeds it happens that the remaining part of the seed so called, viz. the external Bark, is only the Case (as it were) of the true seed which defends the pulp or

The pulp of the seed.

The Bark of seed why made

true

true ſeed againſt external injuries, and that external Bark to the Barks, and Shels, and Membranes of Eggs. For ſince the ſeeds of Plants are not preſently caſt into the Mothers Womb as the ſeed of Creatures that bring forth live young ones is, but are many times kept long out of the Earth which is their Matrix, this Bark defends that ſame internal ſeed againſt the external injuries, leſt before it begins to ſprout, or in the very ſprouting, it ſhould be hurt by external occurrent cauſes.

From which it appears, although (as was ſaid before *cap.* 6.) the ſeed may alſo be called Fruit: yet that there is ſome difference betwixt Fruit and Seed. For that is properly ſeed which is ſimply neceſſary to generation ſuch as is the marrow of the ſeed, which alſo nevertheleſs becauſe it is produced by the Generator it may alſo be termed the Fruit. But becauſe the Creator hath compaſſed ſome ſeeds with Pulps which are not neceſſary for the generation of that ſpecies, but ſerve for meat for man or for other uſes, as in Cherries, Apples, Pears, Peaches, Grapes, all that wherein the Seed is is commonly called the Fruit. And ſo according to nature the Fruit is either Seed, or that which contains ſeed in it, as *Ariſtotle* writes, 1. *de generat. Animalium, cap.* 18. Yet by Art it may come to paſs that the fruit ſo called may be without ſeed: as Cherries without Cherry ſtones, and the Berries of Grapes without ſtones: which is performed by taking the marrow out of the Branch. From which it appears that the Marrow in Trees does chiefly make towards Generation.

Chap. 9. *Of the Generation and Propagation of Animals in General, and of Bruits in Special.*

HAving ſaid thus much in general of the Original of living things, and then more eſpecially of Plants; in the next place we are to treat of the propagation of live things, and firſt of Bruits. Where in the firſt place we are to give warning that ſome think too meanly, yea, and groſly of the Souls of bruit Beaſts. For ſome (truly) there are whoſe underſtanding is ſo plunged in the Elements that they can underſtand nothing above them; and therefore they endeavor to deduce al things out of the Elements, and dare to write that the firſt individuals of bruit Beaſts were totally and according to either part (*viz.* their matter and form) produced of the Elements, and that al bruit Animals both in reſpect of their body and their ſoul are in al generations Elementary, and ſhal continue ſuch to al Generations. But *Scaliger* was much more in the right, *Exercit.* 307. *Sect.* 20. judging of the Souls of Bruits from their actions which are far above the forces of the Elements. For admirable and wonderful actions appear in Bruits, which can proceed from no Element nor Elementary nature, but depend upon a more noble Principle. Such wonderful things are related of the wit and capacity of Elephants, that they ſeem to tranſcend all belief, unleſs they were related by credible Perſons, *Pliny*, *Lib.* 8. *cap.* 3. 4. 5. *Chriſtopher Acoſta*, and at large by *Juſtus Lipſius*, *Cent.* 1. *Epiſt.* 50. What wonderful things in Peace, what admirable things in War an Horſe performs, the ſame *Lipſius* ſhews plentifully; *Century* 3. *ad Belgas*, *Epiſt.* 56. What happened to the Sybarites who could dance both they and their Horſes, Hiſtories teſtifie. And who wil not beleeve the moſt credible *Scaliger* being an Eye Witneſs, who relates a ſtrange ſtory of the apprehenſiveneſs of an Horſe, *Exercit.* 209. concerning *Alexanders* Horſe *Bucephalus* who does not read ſtrange things both out of *Gellius*, and many other Hiſtorians? Alſo what the Sagacity of Dogs is, and their fidelity to their Maſters, and their aptneſs to learn any thing may be learn'd from *Pliny*, *Scaliger*, *Camerarius*, and *Lipſius*, *Cent. ſing. ad Italos & Hiſpanos*, *Epiſt.* 59. & *Cent.* 1. *ad* Belgas, *Epiſt.* 44. yea, and it is manifeſt by dayly Experience. What tricks Apes play, and how they counterfeit mens actions, is unknown to none. That an Hare learn'd to keep company among Dogs without fear, and would go on hunting with them (among many other ſuch things) *Julius Cæſar Scaliger* teſtifies, *Exercitat.* 224. Among Birds *Juſtus Lipſius* reckons the Letter-carrying Pidgeons, in *Epiſt.* 59. *Cent. ſing. ad Italos & Hiſpanos.* Who knows not that Parrots wil learn to ſpeak as men ſpeak; yea, that the Mag-pie, Nightingale, and Thruſh wil do as much, *Martial*, *Plutarch*, *Ovid*, *Pliny*, and many others witneſs. That Cranes journey with a certain Diſcipline and keep watch, is averred by thoſe that write the Hiſtory of Birds. The wit and induſtry of Bees and Piſmires is vulgarly known. Every Cottage is ful of the Artificial Works of the Spider. Beaſts know their own ſtrength and Arms and their own weakneſs, and have their familiar Medicines which they are acquainted with.

whether the Souls of Bruits ſpring from the Elements?

the wonderful underſtanding of Bruits.

Which

Which wonderful abilities and works of Bruits they that endeavor to derive from an Elementary principle do but wash the Blackmore.

And as the Operations of Animals are more various and wonderful than those of Plants; so their propagation is more labored and curious. It is not my intent in this place to propound al that may be said of their differences and various Originals, but only as much as shal suffice to declare the propagation of their souls. Now to the Generation of perfect Animals there is required a double Generator, and neither is of it self sufficient to Generation; though there is a controversie as touching the manner. For I know the disputes betwixt the Aristoteleans and Physitians concerning this point, whiles the former conceive that the seed of the Male is the only efficient, and that the Female affords nothing but matter: but the latter hold that the Female affords seed also which is both effectual and fruitful. Which great Controversie being *prolixe* I think not fit to handle the same in this place. Certain it is that neither Male alone, nor the Female alone is sufficient to generate a living Creature, but both of them contribute their share whatever it is to the constitution of an Animal. Whence *Empedocles* also (as appears in *Aristotle*, 1. *de gener. animal.* c. 18.) said, That it is the joynt contribution of the male and female, but the whol proceeds from neither of them. They indeed that hold that the Seed of the male only does concur actually to generation may easily free themselves from many Objections urged against their Opinion. But most Physitians think the contrary, who hold that the formative vertue is as wel in the Seed of the Female as of the Male; and they conceive they have reason so to think, as for other causes, so because of the likeness of the yong ones, somtime to the Father, somtime to the Mother, and somtime to both: not only when Animals are generated by Animals of the same sort; but then also when Generation is made by Animals of different sorts, wherein the work of the Fathers and Mothers soul does manifestly appear. So a Mule is made of a Mare and a hee Ass, a Mulet of a stone Horse and a shee Ass; of an Ox and an Ass the strongest sort of Mules; the Indian Dog of a Tiger and a Bitch; the Dog-lyon of a Lyon and a Bitch; a strong Dog of a Wolf and a Bitch; the Laconick Dogs of a Dog and a shee Fox; of the Pard and Lyoness the Leopard; a Musmus of a shee Goat and a Ram; and many other Animals: of which see *Johannes Baptista Porta, Lib.* 2. *Mag. Natural.* Yea, and Histories record that a Woman coupling with a Beast hath brought forth a Creature like her self. Yet these men can easily free themselves from dubious objections. For this Law hath been established by the Creator, that as it were from two partial causes one principle and one total cause should arise, from whence one motion and efficiency should arise to the production of the yong Animal, but in a certain Order and Method. Nor should the Mixture of Souls or Forms offend any one in this case, by reason of some feigned Metaphysical Axioms, For the Male and Female are of the same sort, and therefore it is as little absurd that the soul of the two seeds should be conjoyned as for two flames to be united. *Hippocrates* did not count the mixture of souls so absurd a thing, as appears by that Speech of his, *Lib.* 1. *de Vict. rat. text.* 61. *If any man cannot think that souls are mingled, he is void of reason.* Here *Fienus* objects in his 6. *Quæst. de form. fœt.* If the Seeds should be mixed, and the actions of both should concur, their effect would alwaies be mixed, and alwaies half Masculine and half Feminine, and no yong one would ever perfectly resemble the Father or the Mother, but alwaies partly one, and partly the other. Also he thinks it impossible that those two vertues can alwaies so evenly conspire to one effect, but that they should often err, and instead of one part make two; or instead of two one, one formative vertue making one in this place, and of this part of the seed, and the other making another in another place and of another part of the seed; so that Monsters would be frequently ingendred. *Averrhoes* and others do easily answer this Objection who hold there is no active Principle in the Seed of the Female. But they also who hold that there is an active Principle, and a formative Faculty in the Females seed, have an answer for this Objection. How that God made two Sexes, and in al Animals created both Male and Female is a sure thing; but why he made Sexes is known to his own Wisdom. *Plato* relates a Fable in *Symposio*, That in the beginning there was no difference of Sexes amongst Men, and that al were then Hermaphrodites, but because of their Pride and Arrogance God cut Men asunder, and established the two Sexes distinct one from another, so that one could do nothing towards its own preservation without the other. But Sexes are not in Man-kind alone, but in other Animals also.

The Sexes in Animals

The seed of the female is prolifick.

The mixture of Forms is possible.

But to the Objections of *Fienus* it may be answered, That there alwaies appears a sign of the conjunction of both souls, and there is no creature but the yong one does resemble both the Parents, either in the external form of Body, or the dispositions of the mind, or in both.

Yet

Yet it is not neceſſary that they ſhould alwaies equally reſemble both Parents. For if either of the ſeeds be ſtronger than the other the yong wil moſt reſemble the Parent which that ſeed came from. Nor is it any way neceſſary that an Error ſhould be committed in conformation if the ſouls be conjoyned. For they are of the ſame ſpecies & like as when two flames are united they perform one inſeparable effect, ſo two ſouls joyned together do conſpire to make up one effect. And there are alſo examples hereof in Plants; whereof *Scaliger Exercit.* 106. *ſect.* 6. thus writes: *I wil tel you a greater matter which wil more advantage you in ſearching out the manner of Generation, than to know all unprofitable rules and Laws of Cylinders. Set three Date Stones, and ſo many Palmes wil thence grow up, and ſo diſtinct, as the Stones themſelves were; and theſe three branches wil grow together and become one Palm with one Stock. And of theſe Stones no otherwiſe ſet than aforeſaid ſprings the Palm-tree as* Theophraſtus *informs us: one ſtock in number ariſing from three Trunks, ſeparated in Original, Matter, Quantity and Place.* So far *Scaliger*. For every ſtem and each palm firſt ſpringing out of the Earth hath its own ſoul: yet nevertheleſs theſe three Palms grow into one numerical Palm; which is not only to be ſeen in the palm, but in the Ingrafting of all Plants in which the Stock on which the Branch is ingrafted hath its own ſoul, alſo the Branch hath its ſoul: of the branch and ſtock one Plant and Tree is made and furniſhed with one only ſoul. And not only of the ſame ſort, but different ſouls are alſo joyned, as was ſaid, and may be ſeen in the generation of a Mule, in which the ſouls of an Horſe and a ſhee Aſs are joyned, as is manifeſt by the ſhaping of its parts; alſo in the ingrafting of a Pear upon an Apple, and of other Trees of ſeveral ſorts. For where the power and faculty of the ſoul is, there is the ſoul it ſelf: but in the conformation of a Mule the actions of each ſoul, both of the Horſe and the Aſs, are apparent. And therfore here alſo with *Scaliger* in *Lib.* 1. *de Plantis*, we muſt ſay, *where the thing it ſelf is apparent, if Opinion contradicts the ſame, we muſt ſeek a reaſon, and not be Ignorant of the thing.* And therefore whatever objections are made concerning one ſeed whether of the Male or Female, they are of no moment. For neither is one ſeed alone ſufficient for Generation, but both are neceſſary.

The Conjunction of ſouls abſurd.

Now the Generation of Animals is twofold; for ſome bring forth Eggs out of which living things are hatched; others conceive live things within themſelves and afterwards bring them forth. To each of theſe Generations the ſeed of the Male and Female are requiſite, and of them joyned together the Conception is made in which the ſoul is the principal cauſe of the ſhaping of the young Creature. For al the reaſons which prove that the ſeed of Plants is animated, the ſame do alſo firmly prove that the ſeed of Animals is animated; and the reaſons which prove that generation is made in Plants by the animated ſeed, the ſame reaſons demonſtrate the ſame thing in Animals. Some indeed do count it a vain way of reaſoning, to argue and demonſtrate the Generation of Animals from the Generation of Plants. But in my judgment they are therein much deceived. For ſince Generation is an action of the vegetative faculty, or of the natural faculty as Phyſitians call it, and that faculty is moſt vigorous in Plants, the way of generation in Animals may thereby wel be proved. For ſince all Generation is performed by communication of the Soul and the Body, or as *Zabarella* ſpeaks, every Generator when it Generates does communicate ſome of its matter and ſome of its form, and this communication of matter and ſoul is moſt conſpicuous in Plants, ſo that it can no waies be denied that Plants communicate their ſouls by Seeds, Branches, and roots, and that no Generation is made without the ſoul be communicated by the Generator, Why ſhould I not hold that it betides after the ſame manner in Animals? And ſince in Plants the preſence of the form in the ſubject is collected by firm demonſtration from their operations; and in the ſeed of Animals the operations of the ſoul, Attraction, Formation, Augmentation are found, we juſtly conclude that the ſoul is preſent therein. And ſince no Agent can immediatly concur to the production of a living Creature, but it muſt have the ſame degree of life formally; and the ſeed of Animals by its own proper virtue, without any new aſſiſtance of the Generator, or any motion or direction thereof, yea ſeparated therefrom in place, and many times alſo in time, does produce a living Animal, and is the principal and immediate Agent in the production of the young one; it muſt of neceſſity have formally a like and univocal Soul. And this appears both in ſuch as breed Eggs, and living things.

The Generation of living Creatures twofold.

The Seed of Animals is animated.

For in the firſt place, as concerning Eggs, that the ſoul of the future Animal is already in them, this ſhews, that as ſoon as Eggs are cheriſhed by a convenient Heat the ſoul in them begins to rouze it ſelf and forms an Animal, like that from whence the Eggs came. Nor can the Generator be the cauſe of this form; ſince it is many times dead when the Eggs are hatched

Eggs have a ſoul in them.

ched; nor can any other univocal cause be so much as imagined. That the Eggs of Silk-worms are hatched by a temperate heat, *Hieronymus Vida* does testifie in the first Book of his Poem of Silk-worms.

Nor are the Silk-worms Eggs hatched one way
Alone, for some do in the Sun-shine lay
The little seeds, until they hatched are.
Nor shouldst thou be asham'd, O! Lady fair,
To give them (wrapt up in thy Lilly Breast)
Betwixt thy Rosie Nipples a warm Nest:
If thou do'st love to wear a brave silk Gown:
For in a day or two, thou up and down
Shalt see the wonderous little Worms to creep,
Who in their Eggs did lie before asleep.

'Tis commonly known that Hens Eggs are hatcht by Ducks, and Ducks Eggs by Hens. Yea and *Jul. Cæs. Scaliger* relates that in the City of *Grand Cairo* Chicken are hatcht by the Heat of a Furnace. In all which waies there can be no univocal Agent assigned, but the soul which lies hid in the Egg. For the Eggs of Animals being of a middle nature betwixt the seeds of Plants and Animals do agree with both in some things, and in other things they differ: they answer to the seeds of Plants herein, because they contain in them both the soul and the matter of the future yong one; moreover the true seed is covered with a Bark and Membranes: but herein is the difference, that the seeds of Plants when they are committed to the Ground, from it they draw the matter which is necessary to form the body, and of the matter of the seed the first smal Roots and sprouts only are framed, the other parts of matter being drawn out of the Earth: but in Egs since the soul is so barricadoed and shut up in Skins and Shels, that it can draw nothing from without, and in the mean while the yong one is in a manner perfectly formed in the Egg. Eggs do not only contain soul and matter fit to shape the first rudiments of the yong Creature, but also matter necessary to shape so perfect a Body and to nourish the same. And with the seeds of Animals they do herein agree, that the seed is first of all bred in the Stones or the parts analogical to the Stones, and that the seed is perfectly cast by the Male into the Womb of the Female, which is not so in Plants whose seeds are expoied to many external Injuries, being out of the Earth their Nurse. And herein such as breed Eggs differ from those which bring forth living Creatures, in that the seed of the Egg-bearers is not perfected in the Womb of the Females, as the seed of such as bear live young ones is, but is perfected without, and therefore their seed does not remain liquid like that of the others, but had need to be governed by an external help and receptacle.

Eggs compared to the seeds of Plants.

Now the Generation of living Creatures from Eggs is not after one manner. For some are excluded by the Females while they are Egs, and after become Animals being cherished by external Heat. But in Crabs the Eggs stick fast to the Mother, and Crabs are generated in them whiles they are there sticking.

Animals which bring forth quick young ones.

But such Creatures as engender within themselves or in their Wombs, do all generate by the meeting together of the seed of the Male and the Female; which seeds as soon as they are conceived in the Womb the souls displaies it self and begins to frame it self a fitting mansion house, which being perfected is called a living Soul Live-wight or Animal. Now the seed of both the Parents although it hath the soul in it, and therewith lives of it self, yet is it no Animal, nor can an Animal be made thereof unless both are joyned together. That thing is animated which hath a soul in it, and lives thereby of it self: and that is an Animal or living thing which is furnished with a Soul and Body that hath all the Organs requisite to such a Creature. But the seed of the Male or Female alone cannot become an Animal, but the Conception which consists of both seeds, or of the seed and menstrual Blood, becomes an Animal. And therfore the Male does neither Generate in himself, nor doth he engender an Animal essentially perfect, nor does he ingender alone.

The Seed of Animals is animated.

Now that this seed of Animals is animated or hath the soul in it, the Conformation or shaping of the yong one shews. For either the yong is formed by a cause without the seed, or within it. Not without it, for none can be imagined; or if any, it must be the Womb. But that formation does not spring from the Womb is the common opinion of learned men, nor is it destitute of reasons to justifie the same.

Among

Among late Writers (truly) *Johannes Gallego de la Serna, de princip. generat. Lib. 3. cap. 20.* endeavors to prove that the Soul of the Mother is the principal cause of the Organization and Animation in other Animals, and of the formation and union in Man. And to prove his own Opinion he alleadges certain Authorities of some Philosophers and Physitians; but contrary to their own evident Understanding, which therefore I list not to set down in this place: And the Reasons which he uses are evidently frivolous. *The yong ones of Animals are not shaped by the Womb.*

The first is, That there is no Organ in our Body, which by its own similitude and natural Inclination hath the power of attracting any useful substance for attractions sake alone, but to enjoy the same, and consequently to change the same; but the Womb hath a power and most vehement Inclination to draw to it self the matter of the child; *ergo* it draws it not only for attractions sake, but to enjoy, and consequently to change the same. But I answer to the minor, that it is false that the Womb in Creatures that have blood does draw to it self blood necessary to form the yong one; but the soul which is in the Seed draws the same, and therefore also changes the same. For as in Plants the seed cast into the Earth, or a branch or bulb set therein, does first form and produce roots by which it draws nourishment out of the Earth; so the soul in the yong one in the Womb forms the umbilical Vessels, by which it draws blood and spirits.

Moreover he conceives the Generative Faculty hath need of a peculiar Organ, and that the Womb is that Organ, since in the whol body there is none like it so accommodated for such an action.

But both of these suppositions are false. For in the first place the changing faculty is not Organical, nor is it performed in a part as it is Organical, but as it is similar, and furnished with its innate heat. And although the stomach and Liver, and other parts, which do change and generate some substance are Organical: yet they change not nor generate any thing as they are Organical but as they are similary. But they have their Organical constitution for their more convenient Reception, Retension, and Expulsion. So the stomach hath the upper Orifice which receives the meat and drink, the Cavity wherein it holds the same the lower Orifice, by which the generated *Chylus* is sent forth. But Concoction is performed in the stomach inasmuch as it is a similar part, and furnished with its Natural Heat. Again, that presupposition is false, That the Womb does change and inform that blood which comes in for the formation of the Child; since that is done by the soul in the seed. For as when the yong one is formed it hath in it self a nutritive and growing faculty which does not proceed from without: so it is also in the formation or shaping of the said yong one. But the Womb only affords the place wherein the formation is made, and al the Organical Constitution thereof is contrived to that intent and purpose.

On the contrary, There are most evident Reasons which prove that the Womb of the Mother does not perform the shaping of the Child, and that it does not give the soul to the Child, For in the first place, if the Womb did shape the Child or yong one whatever, the Male should not communicate the active Principle of Generation, but only the passive. Yea, and the Female alone should be the cause of Generation, as bestowing both matter and form, and so the female might conceive in her self without a male. Secondly, no reason could be given why the yong one should be sometimes like the Sire or Father. Thirdly, why should not Females be alwaies generated, and how comes there to be Males? Fourthly, That which performs the work Formation must needs immediately touch the Child or yong one: but the Womb does not immediately touch the yong one, but Membranes come betwixt it and the Womb, and those watry Excrements contained in the Membranes. For whereas *Joh: Gallego* conceives it conveighs its vertue to the yong one through the Membranes themselves, it is absurd, nor are the Membranes parts of the yong one, as *Gallego* would have it: Much less can that vertue pass through the Excrements. Nor is that of any moment which he faies of the Torpedoes benumming a Mans hand who touches it only with the end of a very long rope, and that the Load-stone moves Iron through a thick board. For those actions are performed by spiritual Species, as was said before in the Second Discourse, chap. 4. of this Treatise, which are as a Ray continually thrust forth, as *Jul. Cæsar Scaliger, Exercit.* 344. *Sect.* 5. speaks. But the concocting and changing and forming Faculty is immanent, nor does it pass from one subject to another, and remaining in its own proper subject, performs its operations, but does not tranmit its force through the Membranes and excrements out of the Womb. Indeed *Johannes Gallego* conceits that it is the part of a blockhead to doubt, Whether the Soul of the Mother can animate the internal parts of the child, although they are covered with Membranes. But I am of Opinion the quickest wit in the World cannot conceive how the Soul being absent and distant in place, can animate the yong

one. For suppose the Womb could work some alteration thereupon, through the Membranes and Excrements of Water, yet could it not cause animation.

In the seed it self is the Cause of Conformation.

Therefore we must needs hold that the Cause of Conformation is in the seed it self. Which is the common Opinion of learned Men, viz. of *Aristotle*, 2. *de generat. animal. cap.* 1. 3. 20. 1. *de generat. animal. cap.* 20. 21. 4. *de generat. animal. cap.* 1. and elsewhere. *Galen*, *Lib. de format. fœtu. cap.* 2. 3. 5. 14. *Lib.* 1. *de sem. cap.* 8. 18. 2. *de sem. cap.* 1. 2. 5. 14. *de usu partium, cap.* 7. 8. and others. And it hath questionless strong reasons to support the same. For in the first place, since Conformation is a Natural act, it proceeds from an Internal principle, not an external. Secondly, conformation begins in the seed equally, and al the parts within and without are equally conformed. Thirdly, since in Birds which breed Eggs the principle of Conformation is internal, no reason can be shewed why it should not be so in al other Animals.

The soul is the cause of the shaping of an Animal.

And if you now enquire what that internal Principle is, no other can be assigned save the Soul. Some say it is *logos Plasticos*, or a formative Understanding or Faculty: but unless thereby they understand the soul it self furnished with a formative Faculty, this Opinion cannot hold, and hath been sufficiently refuted before, chap. 5. Others hold it is the Native Heat: but neither is that the principal Cause of Formation. For so noble an action which al Philosophers cannot sufficiently admire, can only be ateribed to a quality. And heat is only a common Instrument, nor can it give to al parts their quantity, figure, and number, and out of question no quality can act unless it be directed by a principal and superior faculty, of which there is need in this case.

Nothing else therefore remains which can be the cause of Conformation in the Seed, save the Soul it self. Which while *Thomas Fienus* denies he is in great Error, *quæst.* 5. *concluf.* 6. and in the first place he hath not indeed rightly stated the Controversie. For whereas he ought to have disputed concerning al Souls living, or al Animals, he contrary to the Rules of Demonstration, goes about to demonstrate an adjunct of the whol kind of Animals, touching one sort, viz. Man-kind. For it is not a thing proper to Man alone to generate from seed cast into the Womb, but common to al Creatures which bring forth yong ones alive. And in the beginning of Quest. 5. he does not rightly form the Question, where he writes. The Question here is not, Whether the Soul brought into the Seed after Conception is the Efficient Cause of Conformation? but whether the Soul pre-existing in the Seed before the Conception, and bred in the Testicles of the Parents is the Cause. For there is no Question concerning the latter; but this is the Question in controversie; Whether the seeds of the Male and Female joyned together in the Womb, have an intrinsecal formative Faculty (which he grants) and consequently a Soul (for that necessarily follows) in them.

The Controversie touching the formation of the yong one stated.

For let us put the case that in a Man the Soul is introduced and confused by God: yet since in Bruits there can be no such Infusion it must needs be presently in the seed, and that communicated from the Parents. And this is sufficiently proved by one Argument which *Fienus* himself brings, so that there is need of no more, and that is this; that which shapes the body is within the Seed, as he proved, Conclusion the third. That which shapes is some Soul; for shaping is a proper power of the Soul. *Ergo*, there is a Soul within the Seed, or a Soul of the Seed: for that which he answers (as was said before, chap. 6.) is of no moment. *I confess* (sales he) *the Premises are true. But I deny the Consequence. It is indeed rightly inferred that there is some Soul in the Seed, but not that it is the soul of the Seed. There is indeed a Soul brought into the Seed after that the Seed is conceived in the Womb, or planted in the Earth, or the Egg set under the Hen, when all things are put into act; but that is not the Soul of the Seed, or which did pre-exist in the Seed, or which was bred in the Stones, the Tree, or the Hen, but the Soul of the yong one conceived being afterwards introduced thereinto.* For suppose indeed that the Soul is introduced into humane Seed; yet into the Seeds of Plants, the Egs of Hens, and the seeds of Bruits, 'tis false to hold that the Soul is afterwards introduced. For what introduces the Soul into the seed thrown in the ground, what introduces it into an Hens Eggs whiles a Duck sits over them, or while they are hatched by the heat of a furnace? Here can be no cause assigned by which the Soul should be introduced. And if the Parents should not give the Soul, but some external thing, like should not ingender its like. And what need is there I pray you (in this case) to multiply things to no end, and to hold two Souls; one which is the Soul of the Seed, or which did pre-inexist in the Seed, and was bred in the Stones, or the Tree, or the Hen, and another introduced afterwards. And he contradicts himself in this point, whiles in Conclus. 6. he writes: *That the shaping of the Seed in the Earth is not essential generation it self, but only the perfection of the new Plant already constituted and generated upon the Tree; and the*

'Tis proved that the soul in the seed is the Cause of Conformation.

When a Plant is generated.

the bringing thereof now to a perfect act, which was before constituted only in an imperfect act; nor is it any matter what the vulgar people think or call Generation, or what they do not so call; nor what agrees to their understanding, but what agrees to the Truth. For the common people are ignorant of Philosophy, and knows not when and where a Plants form is truly produced, nor when is the Essential generation of a Plant; and knows not how to distinguish between the first act and the second, betwixt that which is imperfect, and that which is perfect: and therefore they take one for another; *and conceive that a Plant is then first generated when it is perfected and operates, and when it brings forth Roots and Leaves; whose production is not the Generation of the Plant, but the operation and perfection thereof, being generated before.* So far *Fienus*. And in very deed if *Fienus* as he rightly understood the presence of the Seed when Conformation is made, so he had also known the propagation and original thereof he might easily have freed himself from all doubts besides. For the truth in that point being discerned al doubts are easily resolved.

For although they that think otherwise do alleadg many things: yet they can bring nothing solid and firm for their Opinion: which knowing, that they might abuse the Reader contrary to the Laws of Demonstration, such things as they should dispute of the seed and formation of Animals in general, those they dispute in particular touching the Soul and formation of Man; which when they are examined in general and in their own place they prove of no force. For many being of Opinion that the soul of Man is not propagated from his Parents, but infused by God when the body is formed, and the same being also immortal; al those absurdities which are objected against the Animation of Seed from the Prerogative of the Humane Soul do fal to the ground if they be propounded in general so as to concern bruit Beasts also. For they are not able to shew whence proceeds the soul and formation of the Body of an Horse, a Lyon, a Dog, unless the Soul be derived from the Parents with the Seed; nor can they tel us who it is that begins the Delineation of the yong one in al Animals, or why it should be necessary that the said Information should be begun by one, and perfected by another. But especially they are nat able to shew how out of the Eggs of Birds yong ones of the same kind are hatched, especially by a Bird of another kind sitting on the said Eggs, or when they are hatched by the heat of a Furnace, unless the Soul were already in the Egg. And therefore since in Bruit Animals those Arguments are of no force, the most of those also which are urged concerning the Generation of Man wil also be of no force. And although some distinguish betwixt the Conception and the Seed, and cal that white substance bred in the stones the Seed, which is shed into the Womb in the time of Copulation; and that Body bred of the Seed in the Womb the Conception, wherein there are some lineaments of the future Animal already drawn; yet they themselves cannot shew a Reason whence the Soul in Bruits (for here we wil set aside the Humane Soul, thence thereabouts, for the reasons aforesaid there is a peculiar dispute) should come into the Conception, if it were not in the Seed before; nor tel us what cause began that first delineation and figuration of the parts of every Animal. For whereas *Johannes Gallego de la Serna*, saies it proceeds from the Womb, that is altogether false. For so the Female should only generate, since she alone gives the soul, and the Male affords only the matter.

But let us see their Objections. In the first place many indeed Object, and therein also triumph, That nothing is animated but a body and its parts; but the Seed is an Excrement and a certain superfluous moisture bred in the stones, being just like the Chyle in the stomach, the blood in the Liver and Heart, and the milk in the Dugs. But in good deed this Argument of theirs is of no weight, as shal be also shewn hereafter in Chap. 14. For in the first place, they beg the Question, and this very thing is a part thereof, whether only the parts of the body, or the seed also be animated. For although the Seed is bred in the stones, as Chyle in the stomach, and is no nutriment of the body; yet it does not thence follow that it is an Excrement. For there is a third thing generated in living Creatures, viz. the fruit or seed, cal it which you please, which the seed of Plants does evidently declare. For some do make exceptions and say, that there is a difference betwixt the seeds of Plants and Animals, and that the Seed of Plants is not like the seed of Animals, but like the Conception made in the Wombs of Animals. But suppose it so to be; yet thereby is proved, that there is also somwhat bred in Animals which is neither a part of their Body, nor a Nutriment, nor an Excrement. Nor does that prove the contrary which *Johannes Gallego de la Serna* objects, *de princip. generat. Lib. 2. cap. 5.* while he writes that the seed of Animals cannot attain to that ultimate disposition to the Introduction of the Soul, which those parts of the same substances have attained, which have been turned into the substance of the parts; and that the seed hath only received from its organ assimilation, such as the concoctive Faculty was able to

A refutation of arguments brought against the presence of the soul in the seed of Animals.

The seed is not an excrement.

to give it, and such as Milk hath received, and that therefore it remains inanimate. For they are meer beggings of the Question, and the seed of Plants does demonstrate the contrary. For if the seed of Plants could receive that disposition necessary for the propagation of Plants; why cannot the seed of Animals receive the same? And milk it self which *Johannes Gallego* brings for an example, evidently declares that somwhat may be ingendred in the bodies of Animals which is no part of the body nor its Aliment (for the Mother is not nourished with the Milk she breeds) nor a meer Excrement: such as seed also is, which is not therefore bred in the stones by the concoctive Faculty only that it might be voided forth as al Excrements are, but therefore and to this end that by it a new Individual might be generated, and so the kind might be preserved. And therefore though the Concoctive Faculty does not animate the Seed, as neither in other parts does the aliment receive the Soul from the Coctive Faculty: yet after the Seed hath received from the Concoctive Faculty such a disposition that it can be a fit subject for the Soul, the soul which is in the animate body does communicate it self thereto as wel in Plants as Animals: which after it is separated from the Parent, by vertue and power of the soul which it possesses and hath received from the Generator it is able to constitute a new individual, or particular distinct live thing. For in them also the seed is first elaborated by the Concoctive Faculty; and when the seed is wel wrought and ripe, then the soul communicates it self thereto. The same comes to pass in Animals, nor is there any reason to shew that it is otherwise; save that in Animals as being more perfect there is a more labored preparation, and both the male and the female communicates somwhat to the Constitution of the yong one; nor is the seed cast into the Earth, but into the Womb. Nor let that trouble any one that the seed of Animals which bring forth quick yong ones, is of a different Nature from the seed of Plants, and that the seeds of Plants are wonderously and variously shaped: but the seeds of Animals represent only a Liquor like milk. For seeing the seeds of Animals are presently cast into the womb of the Mother, and cherished thereby, and therein receive blood necessary to nourish the yong one; there was no need that they should be fenced against external Injuries, by external coverings as the seeds of Plants and Eggs also are.

How the Seed is animated.

The difference of the seed of Plants and Animals.

Howbeit in the Womb it self the Seeds of Animals do frame many things which are necessary for the Formation and augmentation of the yong one; such as are the Coats which infold the same, the Umbilical or Navel Vessels, and such things as belong to these. Finally, in such Creatures as produce Eggs, because the Eggs were to be kept long before the Chicken are hatched, and that is not performed by the heat of the Womb, but by an external Heat, yet they are covered with shels after the same manner as the seeds of Plants. For Eggs do herein agree with the seeds of Plants, that as in Plants to the marrow or pap which is properly the seed, other things are added either to guard the seed, or to make food for Man-kind, or for other uses; so also in Eggs other things are found besides the true seed. Which does even hereby appear, That the Eggs which the Hens lay untrodden by the Cock have al that is food in Eggs, yet are they untruitful because they want the seed of the male. Which happens also in Insects. Al female Silkworms without difference yield Eggs: but such as have not coupled with the male al their Eggs or seeds are unfruitful. Yet this difference there is betwixt the seeds of Plants and Eggs, that of those things which are added to the true seed, the Plant is neither formed, nor nourished, nor augmented; but the seed draws nourishment to it self out of the ground, save that (as was said before in Chap. 8.) the first rudiments of the tender Plant do draw their Nutriment out of some part of the Pulp; but Eggs, because without the Womb and out of the Earth, they become a perfect Animal, and the seed (of which at first the Chick is formed) is covered with a shel that it can draw nothing from without: in the Egg there lies already so much matter as may suffice to perfect the Chick til such time as it is hatched.

The Objections of Joh. Gallego.

In what sense the seed is more imperfect than the Generator.

Secondly, *Johan. Gallego de la Serna, Lib. 3. de princip. sem. cap. 5.* promises that he wil prove that the Seed is only a material principle of Generation, that no man unless he be blockish and stubborn, wil hereafter dare to deny the same. But he performs not his great Promises, and those are sleight Arguments which he brings. For in the first place he saies that the Seed is much more imperfect than the Generator, and the yong one to be generated. For it is a certain Excrement of the Generator. But I answer, That the seed also of Plants which he grants to be animated, is more imperfect than the Generator and the Plants generated therefrom, not because it hath no soul, but because it hath no formed Organs which lie hid nevertheless aptitudinally in the seed, which contains in it an Idea or Plat-form of them, and they are fabricated by the Soul it self. But that the Seed should be only an Excrement was before refuted.

Again,

Again, He conceits that the virtue of the same sort cannot be received in a matter of a distinct sort. But the form of the seed differs from the form of any Individual of what sort soever. But he does not rightly understand the nature of Seed. True indeed it is the soul cannot persist in a perfect manner, nor last long save in a body fit for it, and furnished with such Organs as it hath need of, but that it cannot be propagated by a different body, viz. the seed, and abide therein so long til it have generated and built a Body for it self, experience it self teaches that to be false, and he himself granted as much before in Plants. For there is indeed one soul in the seed, and in the Animal ingendred thereby: but yet that which is in the Animal differs not from that in the seed, save in the accomodation and perfection of Organs. Verily neither the seeds of Plants, nor the Bulbs, nor the Rootes, nor the Branches (if you consider the perfection of Organs) are of the same condition with perfect Plants, for example sake, the seed and bulb of an Onion after a sort is not a perfect Onion; the seed of Poppy after a sort is not an entire Poppy Plant; the Branch of a Pear Tree is not a perfect Pear Tree: yet in all these there is the perfect soul belonging to that sort of Plant. Nor is the matter in the seed and that in the young one of a different but of one and the same sort.

Whether the Organs introduce the soul.

Thirdly, *Gallego* does also very much urge this Argument, 1. *de princip. Generat. Lib.* 3. *Cap.* 18. when a thing is by Nature & Art so made for some other thing that the latter cannot exist without the former, it must needs be that *that* which is made for the necessity of another should go before it in time. But the matter and all its dispositions are for the form: *Ergo* they ought to precede the same in time. For the form should never be united to the matter save for the Instrumental actions, *Ergo* the Organs and necessary Instruments ought to precede before the Introduction of the form, and the whol preparation of the matter necessary for the actions of the soul cannot any waies be made by the same form whose actions they are, but by the Agent to which the whol work of Generation is committed. For to the same Agent to which it belongs to Introduce the form into the new matter, it belongs also before its Introduction so to prepare the matter that by no means it can be received in another, nor the matter it self can receive the active form. But both the Major simply taken and the Minor are untrue, and the proof thereof is false. That the Minor is false, both the formation of the Body of Plants, and Nutrition and Augmentation of Animals do teach. For first of all, when the seed of a Plant is cast into the Earth, or a Branch or Root or Bulb is set therein, there is no other Agent which can first form the Body and Instruments fit for the soul, but the soul in the Seed, Bulb or Branch, does first form the Roots, by which it draws out of the Earth convenient matter to form a body fit for it self, and of it forms the parts of its own body. Why then should not the same thing be done in Animals? Yea the thing it self tels us that the same is done. For the seed being received into the Womb, the Soul first forms the Membranes in which the seed is included, and then the umbilical Vessels by which it draws blood necessary to form the body withall. Which thing also Eggs do testifie, which being cherished by any heat whatsoever Birds are thence produced. Where no cause can be so much as imagined which should fit the matter to receive the soul save the soul it self which is in the Egg. Again, The proof of the Minor is false, which builds upon that never granted Hypothesis, that after the ultimate disposition of the matter then the soul is educed and springs forth. This indeed is true, that al the organization (as he phrases it) is for the form, that is to say, that the form may have fit Instruments whereby to act; but that the soul could not be there in its first act before it can perfectly operate by the Organs can no waies be proved.

Fourthly, Others object that if the seed of an Animal (for example of an Horse) hath actually the soul in it, the seed of an Horse is an Horse; since the form of a thing being supposed, three things are supposed, the Essence of that thing, the Name, and the Operation thereof. But here is no consequence at all. We grant indeed that the Essence of a thing does chiefly depend upon the Soul, and consequently the denomination, and that from it the operations flow: yet the soul is not the whol thing, but a part thereof. And therefore the other part being wanting, viz. the organical body, the soul cannot be called an Animal.

Whether the seed be actually animated?

Fifthly, Some do Glory in this Argument, viz. that it is a metaphysical Principle, that the same thing cannot be at once actually and potentially. Since therefore the seed is potentially an Animal, it cannot be actually an Animal. But there is no strength in this Argument. For not to dispute in this place of the genuine sence of that metaphysical Axiom, since the same thing in divers respects may be said to be both actually and potentially: I shall only speak to that, whereas the seed is said to be potentially an Animal; and I Answer, That this Argument is drawn from Authority, and that which upon a like occasion the most learned

learned *Thomas Fienus* said from *Plato*'s Charmides; it is not to be regarded what any man saies, but whether he speaks true or not. Again saving the Authority of *Aristotle*, the most renowned *Casparus Hofmannus* hath wel written, as before we hinted more than once, *In tract. de formarum Origine, rat.* 2. *Aristotle* hath so often said that the seed is an Act, that it is the part of a very unskilful Person to urge only those places where he saies it is potential. For seeing (as was said before) that which moves is actually, but the animated seed actually moves, certainly the seed must have a certain act which moves. This act is *that same beginning of Generation and Motion* (as *Aristotle* cals it) 1. *de Generat. An. cap.* 2. *and the beginning of the shape which turns the Courses into its own likeness.* 1. *de gener. animal. cap.* 20. & 4. *de Gen. cap.* 1. 1. *de part. animal cap.* 1. And lest any should feign I know not what spermatick Principle (of which we spake *cap.* 5.) different from the Soul, he terms this Principle, *a member or part of the Animal, which is immediately in the Seed*, 2. *de gen. anim. cap.* 1. And whereas *Aristotle* sometimes saies, that the seed is potentially animated; this he therefore said, as *Scaliger* wel observes *Exercit.* 6. *sect.* 7. not because it needs another substance to draw forth and perfect the same (for so it were but begun) but because it wants perfect Instruments which are in its power to make. Which also *Zabarella* held, who (*de Mente humana cap.* 9.) expressly writes, that the Seed hath a Soul potentially, because its soul does not yet work by its proper Organs.

Sixtly, They say if the Soul frames its own Mansion house, (as is asserted) Why does it not presently frame the same in the seminary Vessels? But let them tel us, why the Soul of a Dog does not see in the Dogs Tail, nor produce Seed, nor form a Body in the same place. For where the Place and Organ is wanting, there no Operation can be performed.

What is the most common action of the soul.

Seventhly, They say if the seed is actually animated, why is there no nutrition discerned therein, which is the most common action of the Soul? But it is denied that nutrition is the most common action of the soul, for vivification is its most common action. For Nutrition belongs only to the Body already formed, and when Nutriment is at hand. Hence the seed of Barly, Wheat, or other Grain lives in the Granary, which *Johannes Gallego* does grant, but it is not nourished, because it is not in a convenient place wherein it may be cherished and receive aliment.

Whether souls are united.

Eighthly, They object if the seed be animated and both the Parents contribute the same, the soul wil be a thing compounded of the soul of the Father, and the soul of the Mother. But mixtion and composition as hath formerly been said does only belong to things of different sorts; but if things joyn which are of the self same sort there is no composition; nor is the fire which arises from many flames united called compound: and the example of Palmes was formerly alleadged out of *Scaliger*. And that example also *Fort. Licetus* (*de perfecta constitutione hominis in utero chap.* 8.) alleadges; that by ingrafting when a branch is put into the trunk of a Tree, two and sometimes more souls do joyn, and yet the Tree is but one, and hath but one soul. Whence that fals to ground which some do urge touching the Commigration of two Essences, and the subsistence of two Essences in one, which they count absurd. For all these things are true only of compleat Essences and which can subsist of themselves; but not of those which are ordained to make up the perfection of one thing.

Whether the Parent in generation looses any of his soul:

Ninthly, Whereas they count it absurd that many souls should proceed from one Parent, and that the Parent in every time of copulation should lose a part of his soul, all this proceeds from their ignorance of the nature of the soul. The soul (as hath been said before) hath no parts properly so called, and it is deprived of no part thereof, but remaining stil the same does variously multiply it self. For though one Tree in one Summer do produce a thousand Apples, and each Apple hath sundry seeds, and out of each of them a like Apple-tree wil grow: yet the soul of the Apple-tree is not diminished but remains totally the same. And the same holds in Animals. And therefore it is more decent to search and admire the wonderful works of God than to calumniate the same. And all those absurdities which are objected against the wonderful work of Generation are nothing but disparagements of the works of God proceeding from Ignorance.

Finally, That the seed is animated, *Thomas Fienus* does (*de format. fœt. quest.* 5.) thus Impugn: Neither the Blood (saies he) nor the Spirits are animated: *ergo*, nor the Seed. He proves the Consequence because they are produced in parts much more noble than the Stones are, viz. in the Heart, the Brain, the Liver, which if they could not impart the soul to the Blood and Spirits, neither can the stones. But the Principal parts have their dignity. And, therefore although the Liver, Heart, Brain, do generate Blood and Spirits:

rits: yet for the Generation of Animals the ſtones have a peculiar ſeed making faculty, ſuch as no other parts have, that of the blood and ſpirits bred in other parts they may form a peculiar matter which is the fit ſubject for the ſoul to be propagated in, which is termed Seed, which is much more excellent than the Blood ſince it is the fruit of an Animal, and the Blood is only the nutriment.

Chap. 10. *Of the Propagation of the Humane Soul.*

AND hitherto we have demonſtrated by firm reaſons (as I conceive) that Plants and bruit Animals are generated by Seed which hath a Soul in it communicated from the Generator; which lying hid in the Seed forms it ſelf a fit Manſion houſe according to the kind of Plant or Animal from whence it came. It remains that we ſpeak of the Generation of Man, concerning which Authors are of divers Opinions. Some had rather ſuſpend their Judgments than determine any thing in ſo difficult a matter. Others hold that as the Body, ſo the Soul of Man is propagated from the Parents into the Children by vertue of the Divine Benediction. Others conceive that new Souls are created for every perſon by God, and infuſed into their Bodies after they are formed, and ſo they aſcribe the production of Souls immediately to God. As to the firſt Opinion, I acknowledg indeed the difficulty of the matter, and I confeſs that it is here dangerous to determine any thing. Howbeit ſince in matters difficult 'tis praiſe-worthy to do a mans endeavor, and we ought to labor with al our might to know the Truth, ſetting aſide the firſt Opinion we ſhal examine and weigh the two latter. And in the firſt place I am not indeed ignorant what Priviledges the Soul of Man hath, viz. To it alone immortality is granted by God, which is denied to the Beaſts, and it alone ſhal be partaker of eternal Bleſſedneſs. But whether the Propagation thereof by the Seed can derogate any thing from this Prerogative of Mans Soul is a queſtion. Nor would I (truly) hereabouts hatefully contend with any man, but I allow every man to abound in his own ſence, and to enjoy his own Underſtanding; but if I may ſpeak my own mind, there are three things which lie me in hand to prove. Firſt that it is more probable and likely that the Soul of Man is propagated from his Parents by vertue of the Divine Benediction. The Second is, That whether we hold the Soul to be created and infuſed, or to be propagated and traduced from the Parents; yet nevertheleſs we muſt hold that the Soul is preſent in the Seed at the firſt conception, and when the ſeed of the Father and Mother are joyned together in the Womb and retained, and as ſoon as ever the work of ſhaping the Body begins, and that no other efficient Cauſe can be aſſigned which performs the work of Conformation, ſaving the Humane Soul it ſelf. Thirdly, though I know great Authors differ in this point, yet (if ſetting aſide Authority, Reaſon ſhal be only conſidered) I ſhal demonſtrate, That ſcarce any ſolid Reaſon can be brought againſt the Propagation of the Humane Soul by the Seed. And whereas this point is diſputed both with Philoſophical and Theological Reaſons, I ſhal not put my Sickle into other Mens Corn, but uſe only Philoſophical Arguments. And if any man wil defend the other Opinion by Theological Reaſons it concerns him to ſee and ſhew how theſe Arguments may be anſwered. Which if he ſhal do I wil not be wilful in defending mine own Opinion, but ſhal willingly follow him that ſhews me better. In the mean time, and til that be done, as far as I am able to judg in this darkneſs and weakneſs of Humane Underſtanding I cannot think otherwiſe. But I give others free leave to think otherwiſe. For I deſire not to be a Dictator, but only to propound my Opinion as wel as others do theirs.

Divers Opinions touching the original of the Soul of Man.

The propoſition of what is to be ſaid of the original of humane ſouls

Now that the Soul is propagated from the Parents into the Children by the Seed is firſt hereby proved, in that (as was ſaid before) like begets its like. Which *Ariſtotle* evidently ſhews, 2. *de Anima, chap.* 4. *text.* 34. where he thus ſpeaks: *This Operation is of all others moſt natural to living things; I mean to ſuch living things as are perfect, not maimed, and which are not born without ſeed: every thing I ſay to beget another like it ſelf, an Animal an Animal, a Plant a Plant, that thus they may continue alwaies, and attain as much as may be a Divine Condition.* For ſince God made every thing in its kind perfect, but Man moſt perfect of al; verily he could not be called perfect, but ſhould according to *Ariſtotle* be reckoned amongſt maimed things if he could not beget another like himſelf, and that intire. And therefore both according to Philoſophers and Divines, Man ingenders Man, and the whol Man an whol Man, which could not be if the Generator did not communicate the Soul. For ſince a Man conſiſts of Body and Soul, if the Soul ſhould not be communica-

The Humane ſoul is propagated into the children by the ſeed.

ted by the Parents, a Man should not engender a Man. Also that a Man communicates his soul to his Child is altogether agreeable to the holy Scriptures. For God, *Gen.* 1. 18. said to Man (as wel as other Creatures) when he blessed him, *Encrease ye and multiply:* by vertue of which Benediction the whol Man ingenders an whol Man; which could not be if the Soul were infused from without. Of which more largely in Chap. 11. For what ever pertains to the Essential Integrity of a Man that is propagated by Generation. But not only the Body, but the Soul pertains to the Integrity or entire being of a Man. And therefore the Soul also is propagated by Generation. Whence also *Damascen, Lib. 4. de Orthodoxa fide, cap.* 7. defines Generation to be the Procreation of an Individual of like substance by the Copulation of a Man and a Woman. Nor is the beginning of the Soul of Man to be fetched from Creation. For every thing that is created is not immortal. Yea, rather whatever is created is of it self mortal. And that some things are mortal, others immortal, proceeds not from the condition of Nature, but from the most free good pleasure of God; who created what he pleased, when he pleased, and how he pleased. And such is the Nature of Man, as God would have it to be; and it is so propagated, retaining its Essence given by God, even as he pleased.

The humane soul is present at the beginning of the Conception.

But let every man hold here as he pleases, and let him beleeve that the soul is infused or propagated: yet this (in the second place) I conceive to be most certain, That the Soul is present immediately upon the first Conception as soon as the seed of the Man and Woman are joyned and retained in the Mothers Womb, and the body begins to be shaped; and he that holds the contrary, whether he stand for the Propagation, or for the Infusion of the Soul, he is in an Error. For there are in the first place some of them who hold that the Rational Soul is not immediately created and infused by God, but propagated from the Parents, who notwithstanding slip back into that vulgar Opinion of the School-men concerning the Eduction of Forms, and hold, That the Soul does not at first lie hid in the Seed actually, but only potentially, and when the seed is somwhat wrought, and the members of the body are in some measure delineated, that then at last by the formative faculty inherent in the seed the Soul is educed out of the power of the matter excited and kindled, so that whereas before it only lay hid potentially, now it begins actually to be, to live, and to inform its body.

The humane soul is not educed out of the power of the matter.

But all which hath been formerly alleadged, Chap. 4. and 5. against the Eduction of Forms out of the power of matter and the formative Principle in the seed do make also against this Opinion, which it is needless to repeat in this place; only I think fit to produce here what is alleadged by *Balthazar Meisnerus*, in *Philosoph. sobr. part.* 1. *sect.* 3. *cap.* 6. *quæst.* 1. And to omit his other Theological Reasons which he brings, many Inconveniencies and absurdities follow from this Opinion. For in the first place an accident, viz. The formative power which is in the second rank of Qualities should produce so noble and excellent a substance, which is absurd. Secondly, the formative faculty should be without a subject. For the Prolifick Faculty is not a faculty of the seed, but of the soul. And therefore where there is no soul there can be no prolifick faculty unless we would have an accident to be without its subject. Again, this faculty in the seed is either corruptible, or not. If you say it is not, then the seed being corrupted either it passes into the soul newly produced, or else to some other place. But neither of these can be. Not the former, because the powers inherent in the soul are produced thereby, but do not produce it. How absurd were it therefore to say that the formative faculty does first raise the Soul out of the seed, and afterwards insinuate it self thereinto, and flow therefrom? Not the latter, because either it would go away by it self, or pass into another subject. The former is contrary to the Nature of accidents which do not subsist separated: and the latter is improbable, because no subject can be named to which it mixes it self. Therefore that Formative Faculty must needs be corruptible; which being granted, it follows that the Soul it self is corruptible and mortal: for an incorruptible thing cannot be generated out of a corruptible.

But those who hold the Creation and Infusion of the Soul do al of them conceive that the Soul is not infused at the first Conception, but when the body is formed.

But they who setting aside Authority and anticipated Opinions are willing diligently to weigh and consider the matter it self, cannot otherwise hold than that the soul of man is present immediately after the first Conception, and as soon as a Mans body begins to be formed. And for the proof thereof I wil use the same Argument which formerly I used in general to prove the presence of the Soul in the Seed. viz. Where ever the operations of the Humane Soul are, there that must of necessity be present. But at the first Conception the operations

The soul of a Man is present at the first Conception.

of

of the Humane Soul are forthwith present: *ergo* the Humane Soul is there also. Now these Operations are first the formation of the membranes which infold the Child, and afterward the shaping of the Child it self, which (as afterwards shal be said) begins at the first Conception. Afterward the augmentation of the Child it self. For sure it is, as soon as the parts of the Child are delineated they begin to grow. But in growing the Soul is communicated to the parts which are added to the Body. Therefore also in the first augmentation the parts which accrew must needs be animated. And absurd it were that the child being born should be augmented by one Soul, and in the Womb by another.

The opinion of Thomas Fienus concerning the presence of the soul in a child in the womb.

The most renowned *Thomas Fienus*, Professor of Physick in the University of *Lovaine*, was moved (*de form. fœt. quæst.* 8. *Conclus.* 11.) by the force (doubtless) of this Argument to dissent from al those who hold the soul to be infused, and that not til about the fortieth day after Conception, and to hold that the Rational Soul is infused the third day after the Conception of the Seed: which he proves by these Arguments. First, That which shapes the child shapes the membranes; but that which shapes the membranes ought to be the third day in the Seed. Therefore the Rational Soul ought to be about the third day in the Seed. For that which shapes the membranes ought to be in the seed before they be shaped, or at the same time when they begin to be shaped; since every Efficient Cause is in time before, or together with the Effect. But the membranes are shaped at the furthest on the fift or sixt day. Therefore they begin to be shaped on the third day at least; and therefore the Rational Soul ought to be in the seed at least on the third day. For two or three daies at least seem requisite to perfect the same; since they have a structure artificial enough, and little Veins and Arteries running through their substance which cannot be formed in a moment of time.

The Coats of the child in the womb are formed by the soul

Now that what forms the Child does also form the membranes, he thus proves: Beings are not rashly and without necessity to be multiplied. Now one and the same soul can perform al the Conformation which is requisite to the seed. For al parts are begun at one and the same time though al do not so in appear perfect. And therefore more than one Soul to shape is needless. Nor can any other soul or vertue be assigned which might form these membranes save the Rational Soul in the seed, which in *quæst.* 8. he proves at large. Yea, and he further shews that it is the Office of the same formative faculty which makes the child to make the membranes also. For in the first place the membranes are shaped for the childs sake, and the Seed is covered with them lest it should be defiled by the filth of the Womb, and the Menstrual blood, lest the seed should run about and slip out of the Womb, and that the spirits therein might not exhale. Secondly, the Membranes are formed of the same matter that the child is formed of, viz. of the seed, and consequently of the same formative Faculty. Thirdly, the membranes live, *ergo* are formed by the same soul wherewith they live. Fourthly, the Navel Vessels are formed by the same cause the child is formed by; *ergo* the membranes also. For the Membranes ought fitly to be joyned to the Navel Vessels, and the Navel Vessels ought to be cloathed by them, and to perforate and go through them. But that union and connexion cannot be made by different formative faculties. And ridiculous it were to think that the membranes are not made by any formative faculty, but are only bred by the heat of the womb as the crust of a Loaf by the Ovens heat, and the skin upon milk by the heat of the fire. For the generation of the membranes and their conjunction and connexion with the Navel Vessels is far more artificial than that it can be caused only by the drying of the fire; nor is it made by necessity of the matter, but it is specialcially intended by Nature, as without which there could be no Child made of the Seed.

The membranes are made presently upon the beginning of the conception.

Now that the Membranes are made the fift or sixt day, Experience it self, and the observation of Physitians does witness; as appears from *Hippocrates*, *Lib. de Natura pueri*, where he speaks of the dancing Wench who cast a Conception out of her Womb the sixt day after it was conceived being covered with a Membrane; *Galen*, 1. *de sem. cap.* 4. where he writes that frequently three or four daies after Conception the seed it self comes away covered with a Coat: And *Macrobius*, in *som. Scipionis*, *Lib.* 1. *cap.* 6. and al observations of later Physitians confirm the same. Secondly, he proves the same hereby, because towards the Introduction of the Soul (he speaks according to his own supposition, or else he would have said propagation) there needs no other action then that seeds should be mixed in the womb by the vertue and heat thereof, and be there fermented and actuated. And to such a mixture fermentation and actuation there needs no long delay of time. For Nature (truly) is not idle a moment, but begins to work as soon as the seed is conceived. And when the last dispositions (he speaks again according to his own Hypothesis) are induced to the Introduction of

the Soul, there is no further need of any other great alteration or elaboration thereof in the Womb. Which he proves by the example of the Seeds of Plants upon which the ultimate dispositions are so imprinted that often of their own accord they begin to sprout on the boarded floors where they lie.

The Authors judgment concerning the Opinion of Fienus.

Touching which Opinion of that most learned Man that I may give my sence; he writ most diligently and accurately above al others touching this matter; and setting aside Authorities, he freely and ingenuously propounded his own Opinion, and confirmed it with reasons, and for the most part held the truth. For in the first Conclusion he rightly proves, That neither God, nor Intelligences, nor the Soul of the World, were the efficient Causes of Conformation; in the second, That the formative faculty is not in the Womb; in the third, That the conformative faculty is in the Seed, and that it is intrinsecal thereunto; in the fourth, That the Native heat is not the principal efficient cause of Conformation; in the fift, That the Generative Faculty of the Parents is not the efficient cause of the conformation or changing of the seed in the Womb; in the ninth, That the Rational Soul is the first and only Soul in the Seed, and that no other does precede the same; in the tenth, That the Rational Soul in Man does shape its own body, and give the same its form; in the eleventh, That the Rational Soul is present about the third day after Conception. And thus from the formation of the Child he perceived evidently and cleerly, that the whol formation thereof was begun, continued, and perfectly accomplished by one and the same soul about the third day, yea, in the end of the second, or rather (since Nature is not a moment idle) as soon as ever the seeds are mixed in the Womb. Which is a thing so manifest that al who hold the contrary must needs fal into most absurd Opinions.

Wherein Fienus comes short.

But since even before the third day (as we shal shew anon) certain operations and some formation is made, he does not shew what causes that formation, either in Man, or in Bruits. Moreover, his Arguments do only prove, That the Rational Soul of a man is present soon after the beginning of Formation: but they do not prove, That the Soul of a Man is about the third day infused, or rather (as he phrazes it) increated by God. For although it be sufficiently demonstrated, That the Rational Soul of a Man is present at the beginning of the shaping of the child; yet another Question does now arise, viz. Whether it be propagated? or whether it be infused by God, and by him created in the seed disposed for it. Where he brings no Arguments nor Reasons for his Opinion, and his other Propositions wherein he differs from my Opinion, viz. The sixt, That the Soul of the Seed is not the efficient Cause of Conformation; the seventh, That in the Seed as it is Seed, and as it is in the Stones, and before it hath received the Soul in the Womb, there is no active vertue of Conformation or Generation; and that the Seed is not an Instrument in Generation, or an efficient, but only a material Cause; and that in neither of the Parents seed there is any active principle of generation, but only passive; the Eighth, That the Efficient of Conformation is the soul which comes into the seed after Conception: al these I say spring from that Hypothesis, viz. That the Rational is infused by God: had it not been for which he would doubtless have acknowledged the presence of the Soul in the Seed. Which Hypothesis nevertheless is built upon Authorities and no sound Reason, as shal hereafter appear; nor do the Patrons thereof bring any substantial proof for it, but only fly to that of *Justus Lipsius*, who when (*Lib. 3. Physiolog. Stoic. cap. 7.*) he had produced the Authority of *Tertullian* and many Latines, who held that the Soul was bred in the seed, and did not enter into the same, and had praised *Gregory Nyssen*, who said none in his wits could think that the original of the Soul was later than the Constitution of the Body, he concludes: *That it was an Opinion which might be maintained, had not the Church the purer sort of Divines agreed to beleeve otherwise: and therefore we must obey.*

Fienus his alse Conclusion.

And that which moved *Lipsius* to deny the propagation of the Humane soul by the seed, and rather to hold that it was infused, that doubtless hath moved others also, and amongst them the renowned *Marcus Marci*, who if he would have contended only with Physical Reasons, questionless he would have granted the propagation of the Hymane Soul by seed. Which appears in that, in *Lib. 1. Ideæ Idearum operatric. cap. 4.* he writes: And if any one would bring a reason of this diversity (viz. That the souls of Bruits are propagated with the seed, and not of Men) I refer that man to the Omnipotency of the Creator, who gives to al things not only such a faculty as is agreeable to their nature, but also their manner, time, number, order, and certain limits. But the Question is not here what God can do, yea, and what he hath done. But it is only pre-supposed and not proved, that God wil not have the Soul of Man propagated by seed; nor if that were held, does it import any absurdity; which does even by that appear which he afterwards adds. But nothing hindred if the Creator had so

so thought fit, but that the Soul of Man might have been so fastened to the seed that it also might be frequently multiplied and born again as it were in particular persons. But the reasons formerly produced do prove, That it so pleased the Creator, nor are there any sufficient reasons to prove, that God would not have it so. *Marcus Marci* endeavors indeed to prove that, when he adds: Yet because it was inconvenient that a Man should be so born, and disagreeable to the end for which he was created, the omnipotent goodness would not have it so. For the souls of Bruits tend only to adorn this world, and because through their corruptible Nature they cannot hold out in one Individual they diffuse themselves into many, that one succeeding another, that variety may be preserved. But the soul of Man does not only adorn this temporary Scene of the World, but is co-heir with the blessed Spirits of the Eternal World to come. Whence of necessity (the act of this life being finished) it is transferred into that same eternal Life which wil make it either happy or miserable. And in case there were but one soul in al, the same at the resurrection of the body should be happy and miserable, beloved and hated of God. But I conceive these reasons are not of sufficient weight. Nor does the propagation of the humane Soul by the Seed make it incapable of another life, nor does it thence follow that there should be one soul of al either now or hereafter. For he himself grants that the Creator could have caused the humane soul to be multiplied in the Individuals. But the holy Scriptures shew that God not only could, but would have it so, when they teach that God commanded that not only other Animals but Man also should beget his like, and multiply himself into Individuals; and the actions themselves which appear in the seed, and other reasons fore-alleadged do prove that several Individual persons have their several Souls, which being immortal shal neither be abolished after death, nor shal grow into one, but each at the last day shal be restored to its Body.

The shaping of a living body common to all living things.

And if (as I hinted before) *Fienus* and other learned men who have written of the formation of the yong one had sought the cause of the formation of a living body, not in Man as being too narrow a subject, but in general in al living things, Plants, and Animals, they had more easily found out the truth. For when (Quest. 5.) *Fienus* was necessitated to grant that the seed of Plants is animated he ought in the next place to have enquired how it is with the seed of Bruits whether it is animated or not, and what therein is the cause of the Conformation of an animate body. And since he himself grants that Conformation begins presently after Conception is made (and he solidly proves there is no other cause of Conformation but the soul, and the soul of Bruits is not infused from Heaven) he might thence have easily collected both that the seed of Bruits is animated, and that the soul therein is the Cause of the Conformation of the body. But seeing those things which he objects against the presence of the Humane Soul in the Seed do also oppose that of the seed of Bruits, he ought to have considered how they should be answered. For if he had done this he would easily have seen how those doubts which are objected against the presence of the Humane Soul in the seed might have been answered. One thing only had remained for him to enquire into, viz. Whether in the point of propagation the Humane Soul hath any thing peculiar to it self, which the bruit Animals have not: and since the formation of the members (which himself makes an argument of the presence of the Soul) begins not on the third day, but at the first moment of Conception, he ought to have proved why that formation should not be a sign of the souls presence.

Fienus does not prove that the Soul is not in the Seed before the third day.

Moreover, neither do the Arguments of *Fienus* prove this, that the soul is not present in the seed before the third day. For seeing as he grants, Nature is not idle a moment, but begins to work as soon as the seed is conceived and the operations begin to be performed in the seed after the first moment of Conception immediately, and as *Galen* hath it 1. *de sem. cap.* 4. three or four daies after the Conception the seed is already inclosed in a Membrane, and the Membranes (as *Fienus* proves) are formed by the same soul: it is truly necessarily concluded, that the soul was present before the third day, and had begun the work of her formation of the humane body. The observations of Abortions do conclude the same. *Hippocrates de nat. Pueri*, writes that he saw a Conception retained six daies in the Womb, and then came away, which was thus qualified, as if a man should take off the outward hard shel from a raw Egg, so that the humor contained within might be discerned through the thin skin. After this manner was that liquor disposed, and it was morever red and round. Also there were seen white & thin fibres contained in the Membrane, with a red thick bloody water, and the Membrane it self on the outside was died with blood resembling the colour of such as have stained faces. In the midst whereof there was a certain smal extant which seemed to me to be the Navil, and that it first breathed therethrough, and from thence was drawn a Membrane which

which imbraced the whol seed. And the same *Hippocrates* in his Book *de Carnibus*, saies tha he Conception hath upon the seventh day all that it becomes the Body to have; and that an Abortion made at this time being put into water does shew to him that shal diligently view all things the rudiments of all the parts of the Body. In like manner *Felix Platerus* writes in *Quæst. med. quæst.* 1. that for many years he had seen many abortions which in the first week were just after that manner: First of all (saies he) that same procreative faculty which lay hid in the seed does rouse it self and disposes those more remarkable portions of the seed which flowed from the three Principal parts of the Parents into three Bladders as it were, swelling with spirits, which are Rudiments of the Brain, Heart, and Liver, shut up in a smal body: and the other portions adhering thereunto it rudely separates into Limbs and Members growing thereto, which are commonly perfected in the first week, so that the Embryon being at that time cast out by abortion, such a shapeless smal lump made up as it were of congealed seed, round and rould together, appears distinguished with the three Bubbles aforesaid. Such as *Hippocrates* observed to come from that same dancing Wench, who caused abortion by her violent Dancing. And I my self saw such a kind of an Abortion like a round white Ball of the bigness of an Hazel Nut, which came from a certain Woman who every year almost did suffer Abortion not many daies after she had conceived: and I took it out of the thin coat *Amnios* wherein it did float, and when I pulled it asunder, I observed three such like Bubbles, the lower of which expressing a rudiment of the Liver was somwhat pale, but not red, also four portions to frame the Arms and Legs, and (which was pleasant to behold) I saw two very little black points marked out for Eyes; which as in others, so I observed the same in a certain Gentlewoman who for two whol years together (which was wonderful and not heard of before) did miscarry every month, and often sent me such an Abortion that I might judg what it was, and I alwaies found them after the same manner.

That the shaping of the Child does begin presently after the first moment of Conception.

Which things being so, it easily appears that the Conformation of the Child does begin at the first moment of Conception. Whence *Macrobius* in his 1. Book *in somn. Scipionis cap.* 6. writes: *that Seed which after it is cast into the Womb does not come back again in the space of seven hours is held to be a due Conception.* And a little after: *that Conception which any Woman holds beyond seven hours is created for life.* And *Ludovicus Mercatus Lib.* 3. *de morb. Mulier. cap.* 6. writes; when the seeds abide in the Womb, and seven hours after are not cast forth, if they be conserved and regulated by the heat of the Womb, it is to be believed that a Woman hath conceived. Hence *Hippocrates* tels us, that the beginning of Conception is to reckoned from that day in which the seed was retained and not from the seventh day, when in his Book *de genitura* he saies, If a Woman be acquainted with Child-bearing, and marks when the Seed does not come away, but abide in her Womb, she may know on what day she conceived.

Conception when it begins.

The Opinions of the Fathers concerning the formation of the Child.

With which reasons *Tertullian* (*Lib. de Anima*) and with him many of the Latin Fathers being moved held, *that a man is sowed or planted in himself or by himself, and that the Seed is alive from the very beginning.* And among the Greek Fathers *Gregory Nyssen, de anima & resurrectione* writes; *no man that is wel in his wits wil imagine that the original of souls is later and newer than that of bodies; since manifest it is, that no inanimate thing hath in it self a power to move it self, and also to grow. But of yong ones conceived in the Womb there is no question made of their growing and encreasing; nor of their motion from Place to Place. It remains therefore for us to hold, that the beginning of the Constitution of the Soul and Body is one and the same. And even as the Earth if it receive a Branch pluckt from the Root, it makes thereof a Tree not contributing thereto the faculty of growing, but only the matter of the growth: so we say, that also which is pluckt from a Man (the Seed) to sow a Man, it also is after a sort an* Animal, *and of an animate thing an animate thing.* And moreover he saies, that all the faculties of the Soul are in the Seed, yet they lie hidden; which in time and order rouze themselves up, and set themselves on work.

Chap. 11. *Whether Like may be said to ingender its like if the Soul be not communicated with the Seed?*

And thus we have proved that it is most agreeable to truth, that the Soul is propagated with the Seed: Secondly it hath been shewed, that the Soul whether it be propagated or infused is present at the first Conception, and is the Builder of its own House. And they that hold the contrary, do two things principally: First, they oppose the reasons brought

brought to prove the traduction of the Soul from Father to Son, and the propagation thereof by the Seed. Secondly, they endeavor to bring reasons to prove the Contrary.

Whether, unless a man communicate the Soul in his Seed he can be said to beget his like.

For in the first place, whereas it hath been said, unless the Parent communicate the soul to his Child in the Seed, like should not generate his like, nor should a Man Generate a Man, but an irrational Creature: many have several waies endeavored to answer this Argument but in vain. For in the first place, whereas some say, a Man may be said to beget his like, if he communicate the immediate matter fitted to receive the Soul; that is of no moment. For Matter does not suffice to constitute his like. And he which does not give the form of a Man, he does not beget a Man. For a Man without his form (which is his Soul) is no Man. And therefore if the Parents do not give the form of a man, they do not beget a man. Yea, and if the Father do not confer the Soul, the Child should neither have Body nor Soul from the Parent according to this Opinion. For *Aristotle* 1. *de gener. animal. cap.* 2. 20 & 21. and 4. *de gener. animal. cap.* 4. denies that the Seed of the Father contributes any part of the matter to the Body of the Child. Which although Physitians deny: yet this is certain, if from the Seed any part of the Body proceeds, that is very little and only the first lineaments of the Body; and *Aristotle* writes that the Body is formed of the Mothers Blood, and that the Father does rather confer the Soul, 1. *de Generat. anim. cap.* 20. *The Male yields the form and the Principle of Motion, but the Female the Body and Matter.* And what we said before in general of the Original of souls, the same must be here repeated, viz. If we hold that the soul is infused into the Body after it is shaped, it follows that they that are dead do generate. For since Generation is the union of the Soul with the Body, and according to their Opinion who hold that the Soul being created is infused by God, it may be infused upon the fortieth day or later, and in the mean while the Father may die: either the Father cannot be said to have begot that Child, or he must be said to have begot it after he was dead.

The Birth does not confer the likeness of Sort, but the Generation.

Again, Some conceit that a Man begets his like in respect of the species or sort, inasmuch as the end of Generation is the perfect nature of Man, and inasmuch as he is not born nor comes into the Light according to the order appointed by God, save with a body and a rational Soul. But this Answer suffices not. For if the rational Soul comes from without, the vital conception is not perfected into a Man, but there is nothing ingendred save an Irrational Animal. Nor is the Question concerning the birth of a Man, but his Generation; which is not performed in the birth, but in the due Conjunction of a Man and Woman according to the Ordination of God. Nor does a man only come into the world, but a Man is also conceived, as it is said of *Cain, Genes.* 4. ver. 1. Adam *knew his Wife and she conceived and bare* Cain. Nor is their objection more strong but the same with this, who say, that if that which is generated by a man is in its time perfected into a man, a man begets his like. For if he hath not his Form and Rationality from his Parents, but from some other, Like is not ingendred by its like.

The Souls of Bruits are not drawn out of the power of the Matter.

The nobility of mans Soul may stand with the propagation thereof.

Thirdly, Whereas some say that Axiom [Every Animal when it generates gives both the Body and Soul to its Issue] is to be understood only of those souls which are drawn out of the power of the Matter, but the rational soul is not drawn out of the Matter, nor depends upon the Body, as to its Essence; that also is of no great moment. For it is falsly and without all Reason presupposed, that the souls of Bruits are drawn out of the Power of the Matter, and depend upon the matter as to their Essence; seeing by Virtue of the divine benediction they are propagated by the Parents to their yong ones. Nor does the nobility of our understanding both in respect of its Essence and Operations shew any other. For so it pleased the Creator to associate a most noble substance to the Body. And therefore if a rational immortal soul can long abide in a mortal Body, Why may it not also be propagated with the Seed? Which if we affirm no absurdity wil follow, as we shall shew hereafter.

Fiftly, Some say, a man does so far beget his like, inasmuch as he generates a sensitive Soul, yea and the inclinations of his Parents to Virtues and Vices, and which is more, Original sin also (they say) is transfuted by means of this sensitive soul from the Parents into the Children. But this is only said and not proved, that there is in Man a sensitive Soul existing of it self besides the rational: And if there were, yet a man by communicating the same should not ingender his like. For the Essence of a man is not compleated by a sensitive soul but by a rational. But whether Original sin in our first Parents did stick only in the sensitive soul, and not in the rational also, I leave to the judgment of Divines.

CHAP.

Chap. 12. *Whether God, or some Formative Faculty does shape the Body of Man.*

Whether God be the Cause of the formation of Mans Body.

MOreover, since that which prevails most against those who deny the soul to be in the seed is the Formation of the body of Man, and yet they wil not be content to submit to the Truth, several men seek several excuses. For since none can deny that same admirable structure of our bodies, they severally invent several Causes to which to attribute the same rather than to the soul immediately present in the Seed. And here some fly in the first place to God the first Cause of al things. So *Alphonsus Caranza* a Spanish Lawyer, *tract. de part. natur. & legit. cap.* 1. when he had rejected al the Causes which others produce, at length he determines the first Cause of the Formation of Man to be God, and the Divine Power and Wisdom, and for his Opinion he brings that in *Psalm* 118. verse 73. *Thy Hands have made and fashioned me.* And that of *Job*, chap. 10. *Thy Hands have fashioned me. Hast thou not poured me forth like Milk, and curdled me as Cheese? Thou hast cloathed me with skin and flesh, and covered me with Bones and Sinews.* But in very truth the Wisdom and Power of God is sufficiently seen in the shaping of our Bodies: but that is not therefore to be accounted the immediate and sole Cause of our Conformation. For the same power and wisdom is seen in the Formation of Animals, yea, and of Plants too. And concerning the Lillies of the Field our Savior saies *Matthew* 6. 30. That God hath cloathed them. As therefore it must not be thence concluded, that God only is the Cause of the Formation of Plants and Animals; so neither may we conclude that he is the immediate Cause of the Body of Man. For God is not the Physical Cause, but the first and universal Cause, not by Natural Motion, but after an eminent and unexpressible manner, as by his presence he conserves al things, cherishes them, and governs them in their actions. Who though at first he created the World and al that is therein; yet he appointed Nature which is the ordinary power of God, according to the Rules whereof the Generation of things is now perfected. That Wisdom (truly) and infinite Power is primarily in the Creator; yet hath he given Power to Second Causes to perform artificial Works, which they also themselves do really accomplish (as was shewed before in chap. 2.) And therefore though it cannot be denied that God concurs in this work as the first and universal Cause (of which Concurrency of God as the first Cause with the second I spake in the foresaid Chapter) yet that he is not the proper Cause does hereby appear, in that Errors do sometimes happen in the Conformation of living Bodies; which would not be if God were the immediate Cause of Conformation. For he never errs in his Actings. Nor could Natural Causes be rendred of those Errors, which nevertheless Physitians do render either from the fault of the Matter, or inconveniency of the Place, or Imagination of the Mother. But the Actions of God cannot be corrupted or marred either through fault of the Matter, or Inconveniency of the Place, or Imagination of the Mother.

Whether a Formative Principle be the Cause of shaping the Child in the womb.

Others seek the Cause in the Seed it self; amongst whom some hold there is a Formative Principle which shapes the Child, and that the Parents use the seed as an Instrument in producing their yong ones. But this Opinion hath been sufficiently examined before, and refuted, unless by the Formative Principle they understand the Soul it self. And to ad this one thing more, a certain late Writer conceits he may avoid al difficulties, if he holds that the Formative Power does not immediately follow the Essence of the Soul, but that by the Divine Benediction it was given to the soul to raise up in the seed a Formative Faculty, which the Seed afterwards being shut up in its place does faithfully retain; and that this faculty does produce a substance, not by its proper vertue, but by that vertue it hath received from the Rational Soul; and that this Faculty when its work is finished does remain joyned to the Soul til the yong one be grown up, and then it puts it self forth again, and infuses into the seed a formative vertue like it self.

Whether any formative faculty can be in the seed without the soul.

But that which is wont commonly to fal out [that they who hold a false Opinion while they strive to shun one absurdity they fal into many] the same hath happened here. For in the first place, whereas every accident requires its subject, and is in the subject by its form: I demand, By what form (if the seed is not animated) this faculty can be in the seed. Which since there can be none assigned there would be an accident without a substance and subject. Secondly, since proprieties are only in one and their own subject, this Formative power should

ſhould firſt be in the ſeed as one ſubject, and after it ſhould be joyned to the Soul as another ſubject. Thirdly, Whereas the Formative Faculty (as by the augmentation of the body, and the regeneration of parts loſt, and chiefly in Plants and Animals does appear) is a proper power of the Soul, it can be no where ſave where the Soul is, and where it is we may firmly and demonſtratively conclude that there the Soul is. Fourthly, it is ſaid but not proved, that an accident by a vertue communicated may produce a ſubſtance. For no accident can ſo much as act, much leſs produce a ſubſtance unleſs it be directed by the Form from whence it flows, and from which it hath its power of acting, as hath been ſufficiently declared before in Chap. 5. concerning the ſeparate Inſtrument. But which way ſoever they explain this formative faculty, unleſs they hold the ſoul to be in the ſeed, they involve themſelves into inexplicable difficulties. For if they hold it to be a ſubſtance they multiply Entities in vain. And ſince al things belong thereto which are proper to the Soul, why ſhould it not be the Soul? But if it be an accident it can have no ſubject, and it wil act beyond its abilities.

Chap. 13. *Whether there are more Souls in a Man than one?*

Whether there are divers ſouls in a Man?

BUt others when they cannot deny the preſence of the Soul in the Seed, and are forced to confeſs that the body of the Child is thereby ſhaped, and yet wil not grant that the Rational Soul is preſent at the firſt Conception, they fancy divers Souls to be in a Man, not building upon ſolid reaſons, but chiefly induced by the Authority of *Ariſtotle*, whom in 2. *de gener. animal. cap.* 3. teaches, That a man firſt lives with a Vegetative Soul, then with a Senſitive, and at laſt receives a Rational Soul. The words of *Ariſtotle* may be ſeen in the place alleadged. But what the ſence of thoſe words of *Ariſtotle* ſhould be, is as great a queſtion as any amongſt the Expoſitors.

For in the firſt place, Some hold that every Soul is a ſimple ſubſtance, and that therfore there does not firſt come a Vegetative, then a Senſitive, and laſtly a Rational Soul; but that one and the ſame Soul in the Conception does firſt perform the Operations of growing, then of feeling and moving, and laſtly of reaſoning. For ſince the Soul cannot exerciſe its Faculties unleſs it be furniſhed with fitting Inſtruments, and does firſt perform the moſt neceſſary actions, and to Nutrition few Inſtruments are required, and that is in the firſt place moſt neceſſary, therefore that is begun in the firſt place to be practiſed; but ſince Senſe and Reaſon does require many Inſtruments, they teach that the operations thereof are exerciſed in proceſs of time, when the Organs of the Body are more perfect.

Others on the contrary do reject this Interpretation, and ſay that it is not agreeing to the words of *Ariſtotle*, while in the place alleadged he expreſly writes that the Vegetative Soul is firſt had in the Conception; and that the Senſitive Soul whereby he is an Animal is received after that, as alſo the Rational by which he is a Man, and that this only comes from without.

Since therefore the Expoſitors themſelves of *Ariſtotle* are doubtful of his meaning, the ſureſt way is to ſet aſide Authority, as is altogether moſt fit in the ſearch of Truth, and to conſider the matter it ſelf, and mannage our buſineſs with reaſons only. Which doing we ſhal find that it is moſt ſuitable to truth to hold that there is only one Soul in Man, viz. The Rational Soul, yet furniſhed with the abilities of the inferior Souls, and beguifted with a Vegetative and Senſitive Faculty. And if the words of *Ariſtotle* admit this ſence, of which I diſpute not, it is a ſence convenient enough. For (which we are to note in the firſt place) the Soul is a ſimple Eſſence, and there is one only Soul in every living thing, but furniſhed with divers faculties. In every Plant there is a ſpecifick Soul; yet that hath ſundry Faculties, it nouriſhes, augments, ingenders Seed, and alſo performs the proper actions of its own kind; and the properties and actions of a Roſe are of one ſort, of Roſemary of another, of Rhubarb of another, of Hellebore of another, of the Eugh-tree of another. Every Animal is nouriſhed, augmented, begets its like, hath ſundry Senſes, is moved, and finally performs that which is proper to its kind; and a Bee hath one ſort of properties and actions, a Piſmire another, a Sheep another, a Crow another, an Elephant another, an Ape another: which are not indeed Rational, yet as the Underſtanding is the ſpecifical propriety of a Man; ſo thoſe alſo (beſides ſenſe and motion, which are actions common to al Animals) have ſomwhat ſpecifical. And if it be not abſurd in a Plant or Animal for divers Faculties and Actions to proceed from one Soul, why ſhould it be abſurd to hold the ſame in Man?

There is one ſoul in a Man.

Divers faculties and actions flow from one ſoul.

Reasons to prove that there is but one soul in a Man.

And that we should hold that there is but one Soul in every Animal from whence divers faculties and actions do proceed, and not divers souls, many reasons there are that perswade us. For in the first place, If there were divers souls in a man every man should not be one Animal, but should have divers operations from divers forms and acts. Whereof *Julius Cæsar Scaliger*, *Exercit.* 307. *Sect.* 5. hath treated largely. There is no reason (saies he) which can perswade me that our Soul (an immaterial substance, and a certain particle as it were of God) should be any waies compounded, especially of two things actually contrary. For I do not think Water is so contrary to Fire, as that which is Rational is to that which is Irrational. The Soul which is totally in every part of the Body, how can it have at once two parts actually contrary one to another? And a little after: For a Man should be so one as an heap of several things laid together, no true Man but a Geryon, and true Chymera or Monster. Nor can those who hold the contrary avoid the force of this Argument, by saying, That there is in Man only one first specifick form, and that the rest are generical and subordinate to the specifical, and that the rational soul in Man as the chief does only perform the office of a form; but the rest though of their own Nature they are forms, and are actually in the living Creature, yet being compared with the principal they are more like matter than acts. We may indeed grant that there may be divers forms in one Individual, of which only one is specifical, and the rest pertain to the disposition of the matter; yet all those forms as they belong to the matter are passively disposed, and the specifick form as the primary Agent uses them as its subject and primary Instrument; and they do not perform such actions as determine and constitute any Individual to be of such or such a sort. But the Vegetative and Sensitive Faculty (they call it Soul) do not pertain to the disposition of the matter, but are primary faculties; and according to their Opinion, the Sensitive performs the office of a specifick form, before the coming of the Rational. And therefore if before the coming of the sensitive soul the vegetative, and before the coming of the rational soul the sensitive should constitute the same Individual, one numerical Individuum should at divers times be informed with divers specifick forms; which is absurd: and so if an Individual should contain divers perfect beings in it self, it would be one by accident, and an heap of things.

There is no vegetative thing but pertains to some sort of vegetables.

Secondly, If a man should in process of time receive divers souls, this absurdity would follow, That there are divers living Individuals which should belong to no sort of live Creatures. For while a man lives only by the vegetative soul he must be a Plant, nor yet should he belong to any sort of Plants; while he lives with a sensitive soul he must be an Animal, but yet not belonging to any sort of Animals. To which reason although some endeavor to answer; yet they alleadg nothing that is of any moment. *Job. Gallego* allows the answer of *Toled.* 2. *de Anima, cap.* 3. who saies, That such an Individual is not essentially a Plant, and therefore is not under any kind or sort of Plants; but that it is contained under the kind of an *Embryo*, and under some sort of the same kind; and that Nature hath made two distinct sorts of Vegetations, the one of which is a Plant, and the other an Embryo or young Conception; and that this kind of Embryo's does contain under it so many sorts of Embryo's as there are of perfect Animals, and that the sort of Humane Embryo's hath a Nature by it self, which as the Instrument of the Generator makes an Organization convenient to receive the Humane soul created by God. But one absurdity being granted a thousand follow, and thus one absurdity is heaped upon another. For if this vegetative degree is common to Plants and Animals, how comes it to pass that from that vegetative soul which is in the Embryo an Horse is brought forth, and not a Rose, or a Dog? And since they make so many sorts of Embryo's as there are sorts of perfect Animals, it must needs be that one Embryo, if it be of a different sort from another, it must differ by some specifical form. But that is of no moment which the same *Gallego* saies, that the vegetative form of an Embryo produced by the Womb of a Woman does not make the Organization of a Plant, nor of another Animal, but rather that of a Man; both because it is directed by the soul of the Woman having the same Organization; and also because of it self it hath a natural Inclination to make such an Organization. For in the first place, false it is, and not yet proved, That the soul of the woman directs that Organization, as was shewed before. Moreover, whence hath it that inclination to such an Organization? Certainly it cannot have it from the common and generical form, but every determination is from the specifick form. And what will it be then when it comes beyond the degree of a vegetative, to the degree of a sensitive Embryo? For since it is then neither a man nor any other Animal (for the sensitive faculty constitutes no particular sort of Animal) what I pray you must it be, since it is constituted in no sort of Animals as wanting a specifick form? Therefore it must needs

come

come to this, That the Soul which is in a perfect Child is also in the Embryo, and that which finishes the work is the same which began it: viz. That the Soul of a Lyon forms it self a convenient body, the Soul of an Horse forms a body fit for it self; and that in the Embryo of a Lyon there is no form distinct from other Animals but the Soul of a Lyon; and that the form of an Embryo (as it is described by *Tolet* and *Gallego*) is a meer figment.

And except this be granted, a reason of the formation of an Humane Conception, of its nutrition and augmentation, and of al the operations performed therein cannot be rendred. For the formation of the child in the Womb, and of al its parts and Organs, as also its nutrition and growth, are quite different from other Animals. For no sort is constituted by divers forms, either at the same or a different time, but by one only, which thence also hath its name, and is called specifical. It does shape it self such a body as answers the Idea thereof in it self, and by such a body performs such actions as by which it is distinguished from other sorts. Hence a man from his own specifick form or soul hath such a body as no other Animal hath, and performs such actions as no other Animal does.

Thirdly, If first the Vegetative soul should inform the body, afterward the sensitive, at last the rational, a Man should be compounded of a Plant, a Bruit, and an Animal. And this absurdity would also follow, That if the sensitive and rational did flow from divers forms, it would be no essential axiom or declaration, when we say a man is an Animal or living thing; for the Nature of the Animal should not flow from the form of Man. But if from both souls the same Attribute should flow, a Man should not be one Animal, but two; viz. An irrational Animal in respect, or by vertue of his sensitive Soul, and a rational in respect of his rational soul.

Nor are the Objections made to the contrary of any weight. For in the first place they say, That many and divers beings cannot proceed from the same Form, nor can the same being proceed from divers and distinct Forms since the Form is the adequate Cause of the Essence. And therefore since the same subject is a Man, an Animal, a living thing, he cannot have these divers beings from one form, but from divers. And contrariwise, Because Man, bruit Animals, and Plants, are living things, and that distinct in their forms, that which is common to al of them cannot proceed from the forms by which they differ, but from that form which is equally in them al. But we deny that the vegetative, sensitive, and rational, are three distinct Beings proceeding from divers forms; but they are only the powers of one and the same soul. And that which hath deceived many is this, That they hold that in some body there may be the vegetative soul alone, in another the sensitive, and that by it an Individual may be constituted. For the Vegetative soul constitutes no Plant, or other sort of living thing, but nutrition and augmentation are common to al living things, and Plants differ specifically one from another as wel as Animals do, and there is one form and specifical soul of a Rose, another of Rosemary, another of an Oak, another of a Pear-tree, another of an Apple-tree; whence, though a Rose, and Rosemary, and an Oak, and a Pear-tree, and an Apple-tree are nourished and augmented; yet they are augmented after a different manner, and each draws a different Aliment, and produce leaves, flowers, fruits, after a different manner; some of them grow to a great height, others creep by the ground, or at least grow not very high. After the same manner sense and motion does constitute no Animal, but al sorts of Animals have their specifick forms or souls, by reason of which sense and motion are in al sorts of Animals different, and the external senses are in several sorts different, as also motion; some creep, others fly, others walk. Howbeit, besides sense and motion they perform actions proper to their kind; a Dog is quick-scented and faithful; an Horse is courageous, and after his fashion proud; an Elephant is discreet in its way; of which see *Justius Lipsius*, *Cent.* 1. *Epist.* 50. the Spider weaves its nets; the Bee makes Honey-combs, &c. For in al living things there is a nourishing, growing, and generating faculty; but these faculties and actions do constitute no sort of Plants; but in each Plant there appear yet other actions which flow from the specifical form as such, and by which Plants differ one from another. In al perfect Animals there is sense and motion, but sense and motion do constitute no particular sort of Animal; but besides sense and motion there are in every sort of Animal other powers and actions which proceed from the specifick soul as such, and whereby Animals differ one from another. Nor are the vegetative or sensitive, or the vegetative, sensitive, and rational, certain peculiar forms distinctly existing, and three Essences. For although they are really somwhat in Nature: yet they subsist not by themselves apart, nor are they any where, or at any time separately existing save in the mind, just as a Being, a substance, and a body; and therefore they do not multiply the Essence of a thing.

Whether a Man hath three Essences?

The Vegetative soul constitutes no Plant of it self.

Sense and motion do constitute no sort of Animals.

From one soul flow all the faculties of the same sort of Animal.

Secondly, They object, that if in a man there be not a vegetative and sensitive Soul, but only their faculties, then there will be a power of a power. But this does not follow, nor does the vegetative faculty flow from the sensitive, nor the sensitive from the rational, but all the three faculties flow immediatly from one soul, as from the same form of Fire Heat and Lightness do proceed.

Thirdly they say: Where there is the operation of any form there is the form it self; but in Man besides his understanding there are the operations proper to other souls, therefore there are in him other souls also. But the answer is the same we gave to the first argument. Nor are the vegetative or sensitive faculties, Powers which proceed from any peculiar and specifick form. A Rose, Violet, Willow, Oak, Dog, Lyon, Ox, are counted so many sorts of living things, but there is no where existent a vegetative faculty which does constitute any species by it self: but the vegetative and sensitive (as was said before) though they may be conceived and considered distinct in our minds, yet they do not any where or at any time exist distinct in nature. And what will they answer concerning Bruits, of which the same question may have place? For when an Horse is formed, that action pertains to the vegetative faculty, and is a work of the formative faculty; but that vegetative faculty, is no peculiar soul different from the sensitive and the specifick which Neighs (for by this mark the unknown specifick form of an Horse is commonly described) but these are faculties of the same soul, which in the first place forms the Organs of Nutrition, as being in the first place necessary, and afterwards the rest.

Fourthly, they object: Where there are operations differing in kind, there also are different forms; but in a Man there are operations differing in kind, Vegetation, Sensation, Intellection: *Ergo* also souls differing in kind. But different operations do only argue divers forms where the subjects are divers. But in one subject different operations may proceed from the same form.

How a Man is at once a Man, an Animal, A Vegetable.

Fiftly, they object: If the humane soul were a simple Nature not compounded of a rational Essence and of a sensitive and vegetative soul, by the same very soul a Man should be a Man, a Beast, a Plant; and seeing whatever belongs to a man that belongs to him of it self and primarily by virtue of his specifick form, a Man should be primarily and of himself, a Man, an Animal, a Vegetable. But a man can no waies be said to be primarily and of himself a vegetable, or sensitive Creature; both because vegetation is a proper passion of an animate body, which is the remote Genus of a man, common to every sublunary living thing, and Sensation is the property of an Animal common even to Bruit Beasts. And therefore the adjunct of a kind does not of it self primarily belong to a sort of that kind. But out of our Answer to the first Argument an Answer may easily be brought to this also. For that which they count absurd is not so, viz. that by the same soul a man should be a man, and an Animal, and a Vegetable; or to say better, should both understand, move, and grow. For neither is an Animal or Vegetable, any thing distinctly subsisting in nature; but as a man by one and the same soul is a Being, and a Substance: so is he also a Living, Sensitive, Moving. Mean while, because these Conceptions are different, some Generical, others Specifical, some most special, we may not attribute the adjuncts of a Being or Substance to the soul of Man as it is rational, and as he differs from all other animals.

Nothing corruptible in the soul of Man.

Sixtly, they say: Corruptible and Incorruptible differ in kind. But the rational soul is incorruptible, the rest corruptible. Therefore they cannot be in one subject. I grant the whol Argument. For neither is the soul of man compounded of a corruptible and incorruptible, either substance or faculty: but the sensitive and vegetative faculty in man are as incorruptible as the rational, since they flow from the same soul.

Seventhly, Whereas *Plato* and those who follow him, do therefore conceive they ought to hold divers souls in a man, because there is a certain fight betwixt the rational part of the soul and that part which is subject to passions; since nothing fights against it self: that by Christians is easily Refuted, who know, that that same fight betwixt the divers faculties of the soul is not Essential thereunto, but came in by the sin of our first Parents.

Let us therefore constantly retain the Opinion of most learned Men, which is guarded with strong reasons, and against which nothing solid can be alleadged; that the soul in every living thing is only one, but furnished with divers faculties which in every Plant performs the acts of Nutrition, Augmentation and Generation, but in each after a peculiar manner, and moreover performs that which is proper to every Plant; whence a Rose differs from an Oak and a Vine: and that in Animals there is somwhat which besides Nutrition, Motion and Sense, performs that which is proper to every Animal. For no Animal is perfected by sense

ſenſe and motion only; but as underſtanding is proper to a Man, ſo in every Animal (beſide the moving and ſenſitive faculty) there is a proper faculty, which anſwers to ratiocination in a man, and by which one Animal differs from another.

Why the ſoul preſently upon its Riſe does not propagate all its operations together.

Now the Soul does not perform all theſe operations together at the firſt Generation of an Animal, but thoſe in the firſt place which are moſt neceſſary, and therefore ſhe does in the firſt place finiſh the Organs of the ſaid moſt neceſſary actions. For not to ſpeak now of the Child in the Womb, but of the Infant when it is born; that it hath a perfect Soul is out of Queſtion; yet it does not preſently Go, it does not Speak, it does not Reaſon: but in proceſs of time it performs all theſe things; but it is preſently nouriſhed and augmented: but when the Organs neceſſary for thoſe other actions are finiſhed and perfected it performs all thoſe things. And hence alſo it happens, that although Generation pertains to the vegetative faculty yet it does not ſhew it ſelf before the twelfth or fourteenth year; although the operations of the ſenſitive and rational ſoul do ſooner exerciſe themſelves.

And ſuppoſe we ſhould grant that the rational ſoul hath ſomwhat peculiar: yet no cauſe can be aſſigned, why as in Plants (which cannot be denied) all actions proceed from one ſoul, they may not do ſo in all other living things, and why the ſpecifical ſoul of every Animal may not forthwith be preſent with all its faculties. Nor can they alleadg at leaſt one probable reaſon whereby to prove that in a Dog, or Lyon, at firſt there is only a vegetative ſoul, and that the ſenſitive and motive faculties do come afterwards. For as it does not follow, that the moving ſoul is not in a Whelp, becauſe it does not run as ſoon as it is born, or in a Chicken or Pigeon becauſe it does not fly: ſo alſo we cannot conclude that in the ſeed there is not preſent the ſenſitive and motive ſoul, becauſe thoſe actions are not performed by the Seed.

And verily thoſe who think otherwiſe do involve themſelves into many difficulties; and whiles they build, now upon Reaſon, now on Authorities and falſe ſuppoſitions, and endeavor to reconcile Truth and Fallehood, they involve themſelves in Labyrinths and Mazes inextricable.

For in the firſt place, *Aquinas* grants out of *Ariſtotle*, That firſt there is only the vegetative ſoul, and that afterward the ſenſitive comes, and then follows the rational. But he holds that the vegetative ſoul periſhes when the ſenſitive comes, and that the ſenſitive periſhes when the raional comes; and that becauſe (5. *Phyſ. text.* 38.) he finds written, that one numerical thing hath only one numerical Act, and that conſequently divers forms cannot be in one ſubject, and therefore he thought, when the later form comes the former muſt periſh.

Aquinas was in the right in judging that one thing hath but one form; and if he had held, that preſently upon the firſt original there is only one ſoul in every living thing, he might have eaſily acquitted himſelf. But while he endeavors to reconcile this true opinion with a falſe one, viz. that at different times different ſouls are produced and come into a man, he fals into abſurdities. For thus the Child in the Womb wil not remain the ſame in number, but wil be a different thing; being one kind of thing when in the firſt daies it is nouriſhed and augmented by the vegetative ſoul; afterwards another when it is governed by the ſenſitive ſoul; and again another when the rational ſoul comes into it. And if the ſoul or ſpecifick form of another Animal, after it comes, is ſufficient for Nutrition, Augmentation, Senſe, Motion, and to perform that which is proper and ſpecifical to every Animal, Why may not the ſame alſo in Man preſently upon the firſt Conception be the Cauſe of Nutrition? And what great need is there to multiply Beings, ſince one ſoul is ſufficient to perform all the actions which belong to every Animal?

The Child is ſhaped only by the Soul.

And the very ſhaping of our Body does ſufficiently ſhew the abſurdity of this Opinion; and that formation is begun and perfected only by one ſoul there are many things which prove. For in the firſt place (as was alſo ſaid before) there is no vegetative or ſenſitive ſoul ſimply exiſting, which is not determined to ſome certain ſpecies. In Plants indeed there is a vegetative ſoul, and in the Conceptions of Animals. But the Vegetative in Plants is ſo ordered by Nature that it draws nouriſhment out of the Earth and faſtens it to the Plant: contrariwiſe the vegetative of Animals draws it not out of the Earth, but in the Womb from the Mother, and after the Child is born out of its Veins. In like manner, the ſenſitive faculty is in a Dog, in an Ox, in a Man. But in an Ox it delights in Hay, not in a Dog, nor in a Man. Mean while, ſince according to theſe mens opinions there are the operations of a vegetative and ſenſitive ſoul in the Child in the Womb before the rational ſoul be preſent, there ſhould then be operations which ſhould proceed from no ſoul. For there could not be in the Child in the Womb the ſoul of any imaginable Plant, nor of any Animal that can be named.

As the vegetative is in Plants and Animals after a different manner, ſo is the ſenſitive in Animals.

Secondly,

Secondly, Since presently after Conception Conformation begins, that should be performed by the Vegetative Soul which is first present. But since that according to the Opinion of *Aquinas* it is soon extinguished, and its conformative faculty is withal abolished (for a faculty cannot pass out of one soul into another) and nevertheless Conformation is continued, it must needs be that the sensitive must finish the same, and when that also is abolished the rational. But it is absurd, that one numerical Conformation should be made by three powers of distinct sorts, or (as they say) specifically different, or the faculties of three souls specifically distinct. And how wil they explain the Conformation of Bruits in which (according to their Opinion) there is no such succession nor introduction of divers Souls? And therefore as in bruit Animals by the same faculty the yong one is nourished, the tenth day, the twentieth, the thirtieth, and al the months of Gestation, or while it is in the Mothers Womb, yea, and al the rest of its life; and al those acts of nutrition do make up one numerical nutrition continued from the beginning to the end of the Creatures life: so also no cause can be given, for which the Child also in a Womans Womb should not be nourished the tenth, twentieth, thirtieth day, al the months of its being in the womb, yea, and al its life time by one Soul.

Thirdly, If the soul which is first introduced is the cause of the Conformation of the parts for the introduction of the following soul it should act beyond its forces. For the vegetative soul hath not the ability to form parts necessary for the following soul being sensitive; nor hath the sensitive soul (I speak according to their imagination of three distinct souls) power to form parts necessary for the rational soul. 'Tis therefore better to hold with *Themistius* that each soul is the builder of her own house.

Secondly, *Alphonsus a Caranza* when he saw that he could not hold divers souls in one Man, he sought another starting-hole, and *de part. nat. et legit. cap. 1. parag. 2. de animatione*, holds a twofold Animation, answering to the double formation of a Man, the imperfect and the perfect; and he teaches, That in the first time of that ruder formation the child lives with the life of Plants, and in the second time with a perfect life, or with a sensitive and rational Soul at once. Now he teaches that by the life of a Plant we are to understand a certain vital and nutritive faculty, but not a true life which is not in Plants; since Philosophers in this manner of speaking do not understand a true life, nor do speak properly, but improperly and by way of similitude. Forasmuch as there is only one soul in man, and one life, and that there is no concourse of souls, following one after another in the same subject, but one soul which is infused after the utmost perfection of the body. And he writes, That *Aristotle* being moved by this reason wrote in 7. *Politic. c.* 16. That to avoid over-abundance of Children (according to the Gentiles Custom) it is lawful to endeavor Abortion, provided it be done presently after the Conception, when the Child lives the life of a Plant; but that after the coming of the rational Soul it is wickedness to do it.

Whether Plants do truly live?

But in good deed, these things are thus said without al reason, and do contain many falsities. For in the first place, it is false that the Plants do not truly live. For though others do otherwise define life, yet which way soever it be defined it properly belongs to Plants as their operations do testifie. And where there is life there is a Soul, and there is no life without a Soul. Since therefore he acknowledges vital Operations in that former and rude formation (and it cannot also indeed be denied) he must needs acknowledg the soul to have been long since present; or let him shew us that subject to which those faculties belong which perform those Operations of nourishing, augmenting, and forming. And therefore secondly, if the rational Soul is not infused (as he holds) before the perfect Formation of the body, I desire him to shew us what it is which forms the body til the thirtieth or fortieth day.

CHAP.

CHAP. XIV.

The Contrary Objections Answered.

NOW that some should think the contrary, and neither allow of the Propagation of the Soul from the Parent to the Child, nor of the presence thereof in the Seed, they are moved with divers Reasons, and most do chiefly urge the prerogative of the Humane Soul; and use three Reasons drawn therefrom, which they fetch out of *Aristotle*, 2. *de generat. animal. cap.* 3. The first is; That cannot be without a body, the action of whose Principles is corporeal, for examples sake to walk without Feet: but the mind alone comes from without, because the corporeal action communicates nothing therewith. But let us indeed grant that the soul separated from the body does communicate no more with the body and bodily actions, and uses no bodily Organ: yet that the soul when it is in the body hath nothing to do with bodily actions, subsists by it self, and therefore is in the generation of a Man created, is false. For the Question is not now concerning the Soul, which hereafter (being separate from the body) shal persist by it self through the singular pleasure of God, as shal hereafter be said; but concerning the work of Generation our Question is, and concerning the Humane Soul as it shapes and informs the body. That this Soul in this life hath no communion with the body cannot be granted. Indeed if the Rational Soul in Man were a peculiar soul distinct from the vegetative and sensitive, this reason would have some probability. But since there is only one Soul in a Man, having a vegetative, sensitive, and rational Faculty, as was proved in the foregoing Chapter, and the Soul of a Man does not only understand and reason, but also informs the body (not of an Hart, or a Lyon, but a Man) nourishes it, augments it, conserves it, and makes it enjoy sense and motion, and that not after the manner of Bruits, but of Men; it is most manifest that it cannot want corporeal Instruments, and that when it informs the body, and performs these Organical actions, it communicates simply with the body. And although in respect of the rational Faculty some of its actions are inorganical, as when it understands the intelligible species without a species, and when it reflects upon it self, and knows that it understands that it is able to know it understands, also when it wills; and indeed the mind does not understand by the body as the means and Organ wherewith; yet because while it is in the body it needs a Phantasm for its object, and as *Aristotle* himself (3. *de Anima, text.* 39.) speaks, the Intellect needs to contemplate the Phantasms; and nothing is in the Understanding which was not in the Sense: certainly the Understanding must needs communicate with the Phancy. Which is sufficiently declared by sundry sorts of mad men, in whom Ratiocination also it self is hurt, by reason of the society it hath with the disposition of the body and bodily Instruments; as also the variety of Wits, whiles some are excellent for sharpness of wit, and others are blockish, proceeds from the same cause. All which things being so, and though the Understanding do not use the body to understand withal: yet since it is necessary that it should speculate the Phantasms, there is no cause why we should so absolve the Understanding from communicating with the body as long as it is therein. Much less is there any cause why at last when the body is perfectly shaped it should come in from without.

Such things answered as are brought against the propagation of the Humane soul.

Whether the humane soul participate with bodily actions

But especially al that have followed this Opinion have been deceived by that false Hypothesis, touching the Eduction of Forms and Souls out of the power of the matter. For since they beleeved the souls of Bruits were drawn out of the power of the matter; they would not ascribe so ignoble an original to the Humane Soul, and therefore they argue; The Rational Soul is not drawn out of the power of the matter, *ergo* it is created. Or, Whatsoever is not made of a pre-supposed matter or subject, that is created; but the Rational soul is not made of another matter or subject, *ergo* it is created. That is the false Hypothesis (I say) which they build upon, That some souls are drawn out of the power of the matter. If (truly) those souls of bruit Animals and Plants did spring out of the power of the matter, it were not absurd to ascribe a more noble beginning to the Soul of Man; but since that Hypothesis is false, and no souls of any kind are (to speak properly) drawn out of the power of the matter; but souls were put into al living things, and received from the Divine Benediction a power to multiply and propagate themselves, nor are they made of the seed as of matter, but are propagated with and in the seed: if the same original be attributed

The souls of Bruits are not drawn out of the power of the matter.

tributed to the Humane Soul, no absurdity wil follow: it namely we shal hold, That being in the first Creation made by the most good and great God, and implanted in the body of Man, by vertue of that Command *Encrease and multiply* it hath received a faculty to propagate and multiply it self in and by the Seed. Nor is the Rational Soul an Essence compleat by it self, as the Angels are, which subsists alone by it self; but it is the one half of a Man which informs the Humane Body, and therefore as its society with the Body derogates nothing from its nobility and immortality, no more does the propagation thereof with the Seed.

whether if the Humane soul be propagated from the Father to the Son, it should be therfore mortal.

Secondly, Many have been moved to hold that the Humane Soul comes from Heaven and from without into the body, because they conceit that if it were propagated with the seed, it must needs be mortal. And in good deed (to speak ingenuously) this is a very promising Argument, and by many variously urged and aggravated. For since the seed is sundry waies shed so that no Conception follows (as when a man spils it out of wantonness; in the Gonorrhea; when a man couples with a woman with child, or with a barren woman, and indeed many waies the seed is often so shed that no formation follows) they conceit it should come to pass that so often the soul of Man (which is otherwise counted immortal) should perish, and man-slaughter should be committed. And therefore by this Argument which they count invincible and unanswerable, being moved, many have held the infusion of souls; and seeing they did acknowledg it necessary that the formation of the child should begin presently after the first Conception, and yet they durst not attribute the same to the Rational Soul, some invented one, others another cause of formation, and attributed the same to a formative Faculty, or to the Womb, or absurdly to a certain sensitive soul present before the rational, the vanity whereof hath been shewed before. But the strength of this Argument is not so great as is imagined. For as *Scaliger* rightly teaches, *Exercitat.* 61. *Sect.* 5. and *Exercit.* 307. *Sect.* 20. God alone is truly immortal and incorruptible, because he only hath his being from himself, and depends on none; but in respect to God al created things are mortal and corruptible, which at the pleasure of the Creator may be deposed from that being wherein they are constituted. Yet some of them are not corrupted, as Angels and the rational Soul, because the Creator wil not have them corrupted, and hath made nothing contrary to them whereby they might be corrupted, nor hath so plunged them in matter as that they cannot subsist nor operate without the same: and so they are immortal not by Nature, but by Grace and special favor, as *Damascen* speaks, *de Orthodoxa fide, cap.* 3. And questionless (as was said in the answer to the foregoing argument) there is great difference betwixt Angels and Men. They have never had any thing to do with matter, nor shal have. But the Humane Soul (while it is in the body) does necessarily use corporeal organs, and therefore it is not propagated without matter. And therefore that is false which they say, if the Humane Soul exist after death by it self without matter, therefore it is also produced without and free from matter. For as it pleased God that the Humane Soul should not subsist without the body, but should naturally have its subsistence in an Humane body; so it is also his pleasure that it should be propagated in and with the seed. In a word: the manner of Generation makes nothing to the corruptibility or incorruptibility of an Essence, but that depends simply upon the will of the Creator who made al things of nothing when they did not exist, and by his power preserves them so long and after such manner as he pleases from sliding back into nothing again. Without which Divine pleasure and peculiar Grace to Man-kind, the forms of men should have perished as wel as those of Bruits. It is therefore no consequence, if the Humane Soul whose natural habitation by the will of the Creator is an humane body, being separated therefrom by death can subsist by the Divine pleasure, therefore of necessity it did subsist out of the body before it was associated thereto. And whereas they who assert the Creation and infusion of the soul do hold that God makes Humane Souls immediately without seed: it is impious to say that God could not also make them immortal by means of the seed. And to those other things that are brought to aggravate this argument, touching the effusion of seed without any conception following: I answer, That the Divine benediction, and those gifts of Grace which God by his free pleasure and ordination hath granted to the seed and soul of both Parents joyned together in Conception, must by no means be attributed to the seed of one Parent alone, not shed after such a manner as is necessary to Generation. Yea, and since neither in other Animals the seed of one Parent hath such perfection that one alone is sufficient to make a Conception, and those attributes which are rightly attributed to the seeds joyned may not be attributed to the seed of either by it self; that is much more true in Man.

But

Why God made Sexes in Animals.

But why God made Sexes in Animals must be ascribed to his divine Wisdom and Pleasure. God if he pleased could have created more Worlds, yet he created but one. For God does not alwaies that which is absolutely most perfect, or seems so to us, but that which is best in respect to the End by him aimed at. And therefore though God had created one man more perfect, and who might have had in him the perfection of both sexes, yet had not the World been thereby more perfect, whose perfection consists in the wonderful consent of al Essences, and in their coordination and conspiration to one End. For one sex being wanting, the life and Society of mankind would be less pleasant (which consists in Wedlock) and less firm. And therefore the most good and great God made a double sex that each might have what to love out of it self, and so not only represent the wisdom of God by knowing, but his goodness also by loving.

Whether the Seed be an Excrement.

Thirdly, they object that the seed is an excrement of the third digestion, and therfore not so noble as to be capable of the rational soul; but that only a perfect Body and furnished with al its Instruments is apt to receive the rational soul. Of this Argument we have spoken in the Chapter foregoing, and in Chap. 6. and 7. where I have demonstrated that the seed is not an Instrument properly so called, nor that any unprofitable thing is generated in the Body; yet in that sence it may be called an excrement inasmuch as it is voided forth of the Body. Otherwise and of its own nature it is the most noble substance of the whol Body, and an Epitomy (as it were) and fruit of the whol Man, as hath been said. Much less is it an excrement of the third concoction: but is bred of venous and arterial Blood, and vital spirits in their vessels, that it may be a fit receptacle to receive the soul. And there in all sorts of Animals it is capable of the soul. And if the rational soul may be received by a Body formed of the Seed and menstrual Blood, Why may it not also be received in the seed?

Besides these three Reasons, some do use divers general Arguments against the presence of the soul in the seed propounded before, especially in Chap. 7. as also the 8th & 9th, which it is needless here to repeat, since they concern not the seed and soul of Man in particular, but the seeds and souls also of Plants and Animals; and *Fienus* himself confesses they are but weak, and also answers them, *de format. fœt. quæst.* 5. But because he adds two which he counts more strong, I must not let them pass. The first (and so the fourth objection which also we propounded before Chap. 9.) is this: Neither the Blood nor the Spirits are animated, *Ergo*, consequently not the Seed. He proves the Consequence, because the former are produced in parts much more noble than the Stones, viz. the Heart, Brain, Liver; which if they could not bestow a soul upon the Blood and Spirits, neither can the Stones do it. But it is there also answered, that the seed is the fruit of a living body, and far more noble and excellent than the Blood and Spirit.

His second Argument and so the fifth objection is: if in the seed of a Man there were a soul it should be either Rational, Sensitive, or Vegetative. But it can be none of these. That it cannot be Rational is proved, First, Because if it were rational, the seed of a Man being in his Testicles or Parastate should be a Man. Secondly, The spilling of a Mans Seed upon the ground should be Man-slaughter. Thirdly, The Seed cast upon the ground must be Baptized, lest the soul should be damned eternally. Fourthly, If the seed were animated with a rational soul, the seed of a Woman should be no less animated than the seed of a Man: and if the seed of a Woman were animated she might engender by her self. Fiftly, if the rational soul were in the seed, either it should be the soul of the Parents extended in the seed, and divided and multiplied according to the division of the seed, or it should be some soul bred anew and produced in the seed or infused by God. But al these things he counts to be absurd. First he conceives that the soul of the Parents cannot be multiplied, because then it would follow, that the rational soul is divisible and consequently mortal, and that all Men have one soul, and that our soul should be a particle of our Fathers soul; and the soul of our Father a particle of the soul of our Grandsire; and at last al our souls shal be particles of the first man, and so communicated by Generation. Al which things he counts to be false & different from the Catholick Religion. Also he saies the soul cannot be produced afresh from the soul of the Father, for so it should be drawn out of the power of the matter and become mortal: nor that it is infused by God, and Created in the Testicles; because there it could never come to a perfect state, &c. Nor does he conceive the Soul to be in the seed, because since a Man hath two Testicles and a Woman hath also two, if in Copulation animated seed should fal from four Testicles, four souls should be united, or one should be coagulated of four glewed together. Secondly, Because then the seed of Animals should be a Plant; and a Man before

he should arrive to a rational soul ought to pass through the form of a Plant, and afterward through the Form of a Bruit, and be once an Ass or a Dog. Thirdly, Because that Vegetative Soul should be produced by a Rational soul existent in the Testicles, which cannot be, because the Rational Soul cannot have the power to produce a Vegetative Soul, since those souls are species distinct one from another. And many other absurdities he objects in case we shal say that the Vegetative Soul is in the Seed, which for brevities sake I omit.

But I wonder that so renowned a man, and who in the beginning of the foresaid Book writes, that no man had found out the efficient cause of shaping a man in the Womb, or if some few had smelt it out, they had neither cleerly opened nor by any reasons maintained the same, but that he would prove his opinion with such firm and evident reasons, that no man should afterwards have occasion to doubt, should use such frivolous and light reasons in so serious a matter. For first of all intending to write accurately of the Efficient cause of the Childs formation, he ought to have remembred that a Physitian must borrow many things of the natural Philosopher, that he may attain to the knowledg of the Subject he is to work upon; but because he doth not equal Causes with their Effects, nor adjuncts with their proper subjects, viz. such to which they belong primarily and of themselves, and inasmuch as they are such, his discourse breeds no true knowledg, as *Jacobus Zabarella Lib. 2. de Method. cap.* 11. teaches. For since it is not Man alone that is formed in the Womb, but also other Animals which bring forth live yong ones; moreover Animals are hatched out of Eggs, Plants are formed out of their Seeds: he ought to have enquired in general of the Generation of all Animals, yea of all living things, and what Cause did shape both Plants and all Animals; and the Cause being found, to consider whether it belong to a Man also, or whether we are to hold a peculiar Cause of the Conformation in a Man, and to render a Reason why that power which forms other Animals hath not place in a Man, but that another ought to be sought out. Again, he ought to demonstrate and not barely suppose it as a thing granted, that there are three sorts of souls in a man, and not one furnished with divers Faculties. Thirdly, he ought also to have noted this, that not the Seed of the Man or Woman alone does suffice to produce the Child, nor is the seed cal'd a Conception whiles it is in the Testicles, but when both Seeds are joyned in the Womb, which things being observed he might easily have answered all his own Reasons. For in the first place, he might easily have marked that the Seed of a Man whiles it is in the Testicles does not suffice to Generation, and that therfore when it is shed upon the ground it needs not be Baptized, nor does the Womans Seed alone suffice for Generation. And whereas he conceits that it is false, absurd, and different from the Catholick Religion, that the Soul should be propagated from the Father to the Son; indeed it is not agreeable to the Doctrines of the Schoolmen, but it is nevertheless most true and agrees with the holy Scriptures. For how shal that Precept *Encrease and Multiply* be fulfilled, unless from the first Man and Animals at first Created all the Men and Animals that do live and have ever lived unto this day had received their Souls? And in *Genes.* 46. 26. it is said that Sixty six Souls came out of the Thigh of *Jacob*; and *Exod.* 1. 4. that the Souls that came out of the Thigh of *Jacob* were Seventy, which I nevertheless do leave to the consideration of Divines. Nor does it hence follow that al men have one Soul or that the Soul is mortal. The first Man had one Soul from whence al came. Nor is there any reason that the Soul of Man if it be multiplied should be mortal: for the Creator commanded that it should be multiplied, and nevertheless it was his pleasure it should be immortal. Which things being granted, al the rest falls to the ground, so that there is no need of an Answer. Also it wil appear from what shal be said against the sixth and seventh Objection, what is to be answered to the rest; and that though the Soul be communicated from the Father and Mother, that yet it is not compounded.

With what Soul the Seed is animated.

Sixthly, Some late Writers do thus argue; Either the Seed is animated by the Soul of the Parent, or by its own proper Soul. Not by that of the Parent: for then the Soul of the Parent should become the Soul of the Son; and should go out of the Parents Body with the Seed. Nor with its own Soul; because since both Parents contribute Seed, the Son should then have a double Soul, or one should grow to the other and it should be compounded.

But if this Argument were objected against the Generation of Plants and brute Animals, that which a man should then Answer may here also serve for an Answer. Moreover, I say in general that both in Plants, Bruits, and Mankind, the Seed is animated with the Soul of the Parent, viz. according to the sort; for otherwise like would not beget its like. Also

true

true it is, that the Seed hath its own Soul, and that numerically different from the Soul of the Parent. Yet thence it does not follow, that after this manner the Soul passes out of the Parents Body with the Parents Seed. For the Soul of the Parent remains perfect and entire, although it multiplies it self. And as it does not follow, when in augmentation and in the shooting forth of the new Boughs on a Tree the Soul diffuses it self into the new matter and cloaths it self therewith, that it goes out of the former Body: so it does not follow when it communicates it self to the Sed, that it goes out of the Generator. For this is the force of the Divine Benediction, that the same Soul remaining perfect and entire should be able to multiply it self. And whereas it is said that the Soul of the Son should be double, or compounded, this may easily be answered by those who hold, that the Seed of the Father or the Mother only is prolifical. Nor do they want an Answer, who say that the Seed of both the Parents is prolifical; and before *cap.* 9. we have answered thereto, viz. how that the Souls being of the same sort when they are joyned together do not make a compound; and it hath been said before Chap. 9. out of *Scaligers Exercit.* 106. *sect.* 6. that of three stems of a Palm joyning together one Palm-tree is made, and a flame made of ten Torches or Links is called but one flame, and not a compounded flame. And if it be commonly said without absurdity that the soul is totally in the whol body, and totally in any part; why should it be absurd to hold that the soul is totally in the Mans seed, and totally in the Womans? And moreover, as the whol soul is said to be in the Eye, the Brain, the Heart, nor does it therefore follow that one soul is compounded of many souls; but this continues stil a truth, That it is one Soul which informs the whol and al its parts: so although it be said that the seed both of the Man and Woman is animated, it does not therefore follow that one soul is compounded of two souls, or one made up of two.

The soul of the Parent in generation remains entire.

Another forms the same Objection after this manner: if the Soul of a man be propagated, it is done either by cutting off some part of the soul of the Parents, or by the instrumental efficiency of the seed, or the soul of the child is immediately produced from the soul of the Parents, so that the seed hath no hand in the production of the soul, but only causes the dispositions, or at most is the Vehiculum of the soul by which it is carried from the soul of the Parents into the Child.

But al these Objections arise from ignorance, because they know not the nature of the soul, nor how that saying is to be understood, that every form and soul does multiply it self, and how that Divine Benediction, *Encrease and multiply*, hath hitherto been effected, and is stil effected: but if they did diligently consider, and in the first place search out how souls are multiplied in Plants and Animals, also the manner how the same is done in Mankind, if (I say) they understood these things as far as they may be known in this darkness of our Minds, they would not invent so many absurdities. For the last (if rightly explained) is true, viz. That the seed (understand the body of the seed) is the Vehiculum or carriage, by which the Soul is communicated from the Parents to their issue: which action is called traduction or delivering over, the word being borrowed from Plants. For as in Trees in which the seminal faculty is diffused through their whol bodies, if any part be cut off, and grafred upon another Tree, the soul of that Tree from whence the branch was taken is communicated to the Tree upon which it is ingrafted: so with the Seed the soul of Animals is transplanted into the womb of the Female, and so from that seed endued with its soul a perfect Animal does spring up. But as, when a branch is cut from the Tree with its Soul in it, that Tree neither loses its soul, nor does that soul become less: even so when the soul of the Parent in the seed is delivered over unto the issue, the soul of the Parent remains intire. And as when in augmentation the soul is communicated to the aliment flowing in, the soul which is in the rest of the body does not become lesser; and as when from a root or stem of a Vine, or the root of an Hop, many and long branches grow up in one Summer, all which receive their souls from the root and stem, and yet the soul is totally in the yong branches, and totally remains in the old stock or root, not being made lesser: so also the soul of the Parent is transplanted with the seed into the child, it self nevertheless remaining entire. And this multiplication of souls presents an image of the immense and infinite God, who (as *Julius Cæsar Scaliger* speaks) *reigns every where without place, al without al things, and the whol without parts.* I said an Image. For God the Beginning of al things is an infinite fulness, filling al things, whom neither the Heavens nor Earth do contain, totally existing within the World, totally without, and yet restrained within no limits. But our soul indeed is joyned together by dimentions, and its fulness is only so large as the body is, and bodily dimentions: yet though we should suppose a body to grow from the smallest quantity

The Traduction of the Soul what it is.

to the greateſt bulk, the ſame ſoul would fil it al remaining the ſame without any Addition. Alſo in like manner, though an Animal generate often, and the ſoul multiplies it ſelf, and communicates it ſelf to the iſſue, it is not diminiſhed of any of its parts as having none. Of which we have ſpoke more largely before, Chap. 9. Which things it were better attently to conſider, than to oppoſe the truth though far out of ſight.

Eightly, Neither are thoſe things of any great moment which *Aphonſus Caranza* here objects, and whereby he would prove, That the Rational Soul is infuſed at the laſt when the body is perfected. For in the firſt place, as to that place in *Exodus*, 21. which he cites out of the Septuagint, and proves afterwards from *Philo*, *Lib. de ſpecial. leg.* viz. If the Infant were not ſhaped he that ſtruck the Mother ſo as to cauſe Abortion ſhould be fined, but if it were ſhaped he was to be puniſhed as a Man-ſlayer. I (truly) wil not put my ſickle into other mens Corn; yet thus much I ſay, That which he alleadges is not in the Hebrew text, nor can it be proved thereby that the ſoul is not preſent at the beginning of Conception. And let us ſuppoſe there was ſuch a difference of penalties, and let the Civil Laws and Lawyers here quoted by *Caranza* retain their Authority: yet thence it no waies follows that the Seed is not animated preſently upon the Conception. The Law-givers perhaps, and the Lawyers had their Cauſes known at home, into which I ſhal not now enquire, and which I leave to their place, why they would otherwiſe puniſh him who deſtroys a Conception perfectly ſhaped, than they would do him that deſtroys one leſs perfect; and this perhaps amongſt the reſt was not the leaſt, that before the Child begins to be moved there is no ſuch great certainty of its life, and many things might happen to it in the Womb, although no external cauſe was added, which might take away its life before it came to ful perfection; ſo that what *Hippocrates* ſaies of the Child born in the eighth month, *it is not, and it is*, that may much rather be ſaid of ſuch an imperfect Conception; and therefore they would inflict a greater puniſhment upon him who ſhould deſtroy a perfect Child, and upon him a leſs that deſtroyed an imperfect one of leſs hope, and ſubject to more caſualties. Mean while I conceive it never entred into the thoughts of the Lawyers, that by their Laws they would derogate from the principles of Nature, and oppoſe ſuch things as Natural Philoſophers and Phyſicians (to whom in ſuch Queſtions they alwaies appeal, and whoſe Authority they reverence) do demonſtrate by moſt firm reaſons to be true. Which appears moſt evidently by *Auguſtus*, *conſtitut. quart. part.* 4. whereby it is inacted that he ſhould not be puniſhed by the Sword, but according to the diſcretion of the Judg, who gave a Medicine to procure Abortion, if the Child were not yet quick, and was caſt forth before the middle time, reckoning from the Conception. No man (certainly) wil ſay that a Child is not quick at the end of the fourth month, and at the middle of the time betwixt the Conception and the Birth, ſince al men count the fortieth day the longeſt term in the ſpace whereof the child receives the Soul. Yea, and before the Nativity the Lawyers count not the child a man, *per text in L. cum inter Veteres*, *Codice de fidei commiſſ.* But what Natural Philoſopher wil ſay an Infant is not a Man til he is born? And therefore by a vital child the Civil Laws underſtand ſuch an one in which the manifeſt ſigns of life appear, eſpecially from the motion thereof, which firſt happens about the middle time of Conception. Concerning which thing *Thomas Fienus* does alſo wel write in *Apolog. adverſ. Sanctacruz*, That he who kils an animated Conception, however ſmal or imperfectly organized, wanting yet ſenſe and motion, is a murderer no leſs than if it were perfect; but it does not thence follow that al homicide ought to be puniſhed alike; ſince though both are alike perfect eſſentially, yet are they not alike accidentally perfect. Would not (adds he) any man think that a greater injury was done him by him who had hewn him down a very tall and fruitful Pear-tree, than by him that ſhould pluck out of the Earth and break a ſmal branch only, a foot high, newly planted, and that therefore he is worthy of greater correction, and more ſtripes.

Nor is that argument which he brings in the Second place, of any great moment; whereby he concludes, Becauſe God made *Adam* of the ſlime of the Earth, and when he was formed and faſhioned, breathed into his face the breath of Life; that therefore in Generation alſo the Rational Soul is not infuſed before the formation of the body. But Creation and Generation are of a different Nature. The Woman was created of the Rib of the Man, yet is ſhe not ſo generated.

But in the third place, I admire that a Chriſtian ſhould endeavor to prove by that action of *Hippocrates*, *de Nat. pueri*, That the Rational Soul is not in the Child the firſt daies. For inaſmuch as *Hippocrates* adviſed the Dancing Wench with child, that within the ſixth day

day she might cast out the seed by dancing, he conceives that *Hippocrates* thought that the seed retained so long in the Womb had not the rational soul in it; for otherwise he would not have perswaded her to cause Abortion. Moreover he brings for the same the Authority of *Aristotle*, who *Lib. 7. polit. cap.* 16. allows the destruction of a child in the Womb as long as it is not furnished with sense and life, as if he did suppose that the Conception was without life some notable space of time. But *Johannes Baptista Sylvaticus*, because of this very place, does conceive (and that not without cause) that the Book was not written by *Hippocrates*, *Controvers.* 32. and if it were written by him, yet this Counsel of his is by no means to be allowed, but is to be reckoned amongst the foolish Imaginations and Ratiocinations of the Pagans, of which St. *Paul* speaks *Romans* 1. 21. And the like reckoning we are to make of that same destroying of Conceptions used by the Heathen, of which *Aristotle* speaks, *Lib. 7. politic. cap.* 16. And therefore also that Decree of the Canon Law, in *Decreto in cap. sicut ex Literarum, de Homicidio*, where a Monk by whose assistance a woman had procured her self Abortion, is not counted irregular, and is allowed to say Divine Service, because the Child (as was thought) did not live, is by *Franciscus Ranchinus*, a most learned Physitian, in his Commentary on *Hippocrates* his Oath, rightly termed unjust, and that distinction faulty.

If yet any further Objections may be made against our Opinion, their Refutation is sufficiently apparent from what hath been said. The sum whereof comprehended in the words of a certain great Divine, is this: An whol Man according to the Primitive Ordination of God begets an whol Man. An whol Man I cal a Male and Female, who are made into one flesh, or become one flesh, *Genes.* 2. 24. *Matth.* 19. 6. *Ephes.* 5. 31. Now the Parents generate inasmuch as they are men, that is, according to that which belongs to the whol species or sort of Mans Nature, in vertue of that Divine Word, *Gen.* 1. 28. *God blessed them, and said, bring forth fruit, and multiply and replenish the Earth.* And they generate by the conjugal conjunction. Nor does the male ingender alone, nor the female ingender alone, not the Body only, nor the Soul only, but the whol Man, viz. Male and Female coupled according to the Ordination of God, And therefore a Son or a Daughter proceeds not from the Father alone, or from the Mother alone; but the Son and the Daughter is from the whol Father, and the whol Mother, and equally the Son and Daughter of the one as of the other; and as the Generation of the Parents is common, so the work of Child-making or Filiation, is common to both as to Nature.

The Conclusion.

And thus I conceive I have delivered the true Opinion concerning the Generation of living things, and the propagation of Souls by the seed from the Parents to the Issue, both in Plants and Animals, yea, and in Man himself; and established the same by firm reasons, and refuted the Objections of those that are contrary minded. In the mean while by the admonition of *Scaliger*, *Exercit.* 297. I see, observe, and remember, how weak the sight of our mind is, to search into the secret Closets of Nature; and I hear al learned men in a manner (especially in the Question of the Original of the Humane Soul) complain of the obscurity and difficulty thereof. And therefore I also (peradventure) may be deceived and err. Yet this I conceive I have demonstrated by a most firm reason from the Act to the Power, and from the Power to the Act, or Form and Soul, that there is the Soul in the seed both of Plants, and of Animals, and of Man himself (whether it be propagated by the Parents, or sent in by God) as soon as ever the formation of the living body begins. And this Tenet I shal so long maintain til it shal be to me demonstrated how without the souls presence this work of the formation of a living body can be performed. Which unless it can be done it wil be the part of a mind studious of the Truth not to labor how to oppose that most firm demonstration by certain Objections, and so to render it suspected, but rather to be careful how to answer his own doubts. For *Julius Cæsar Scaliger*, in *Lib. 1. de Plantis*, writes from *Aristotle*; where the thing it self is apparent, and Opinion opposes the thing, we must seek a Reason, but not be ignorant of the thing. Now that thing is appa-

rent which is demonstrated by most firm Reasons. And here at last I solemnly protest that I acknowledg and confess the Excellency and Eminency of the Humane Soul, and its difference from the Souls of Bruits; that it alone bears the Image of God, is separable from the Body, and immortal. And therefore, if I have said any thing (as I hope I have not) which may really oppose this Prerogative of the Soul, I wish it were unsaid. But whether the propagation thereof from the Father to the Son, do that, and whether therefore it must necessarily be held to be immediately infused into our Bodies by God; I leave that to the Judgment of every Man. What seems to me most probable I have freely declared.

THE

THE FIFTH DISCOURSE.

Concerning the Spontaneous Generation of Live Things.

Chap. 1. *False Opinions concerning the Spontaneous Original of Living Things.*

BEsides the Generation of Living Things of which we have hitherto spoken, and which, because *like* evidently Generates its like, is commonly termed univocal Generation, there is yet another, which because therein *like* is not thought to generate its like, it is called vulgarly Spontaneous and equivocal. So, of Horse-Dung those flies are Generated which we cal Beetles, of Corne a certain Worm called in some places a Wibble, of Beans another sort of Worms, of Wood another, of the foulness of the Skin and Garments Lice and Fleas, as also out of Cheese and Flesh and other putrefying things Worms and Insects commonly so called, of sundry sorts do arise, as shal afterward particularly appear, The consideration of the Generation of which kind of Living Things is necessary and not unworthy the Cognisance of a Natural Philosopher; which very thing *Aristotle* did hint, when 1 *de Part. Animal. Cap.* 5. he thus wrote: *With a certain Childish scornfulness to despise the disputation and Consideration which may be had concerning the meanest Animals, and to count it tedious, is no way beseeming a Philosopher; since there is nothing in Nature in which there is not somwhat to be admired.* And as it is reported *that* Heraclitus *said to those that came to speak with him, and because they happened to find him sitting by chance in a Bakers Cottage to Warm him at the Oven, they would not go to him, as abashed at his homly manner of sitting in such a place: for he bid them enter boldly, since even this place* (quoth he) *is not void of the presence of the immortal Gods: the very same may be said touching the Inquisition into the Nature of Animals. For we ought to contemplate and discuss all things without shame; since in all things the Divinity of Nature and her Honorable and Beautiful contrivance is conspicuous.* And that so much the more diligently, inasmuch as few have written any thing that is solid and agreeable to truth, concerning this subject. Above all others the most Renowned *Fortunius Licetus* Professor at *Padua* hath written most diligently and largly of this Matter, in his 4. *Books of the Spontaneous Original of Live Things.* As for me, though I acknowledg the difficulty of the matter, and am well aware that it is dangerous to hold any thing different from the vulgar opinions, and liable to detraction, especially in this subject: yet I had rather freely shew my judgment in an obscure matter and contribute mine assistance, then to cease from the investigation of truth. Let every one follow what Opinion he pleases. I obtrude mine upon no man. And if any man will shewe me better, I shall willingly assent unto him.

The generation of Live things how manifold.

Now this Generation, as hath been said, is by some called Spontaneous (*Aristotle* 1 *de Generat. Animal. Cap.* 1. saies that such Creatures are Generated *by Nature working of her own accord*, and thence *Julius Cæsar Scaliger* borrows the Phrase of *Automatismos*, production of it own accord, *Exercitat.* 168.) the word being transferred

Spontaneous Generation what it is.

ferred from moral actions to Natural. For *Scaliger* conceives, *Exercitat.* 77. *Sect.* 1. that this Adverbe *Sponte*, (of it own accord) was derived *ex sponsionibus*, from promises. Now all promises are voluntary and free. And the same *Scaliger* conceives *Exercitat.* 140. that it cannot be accurately or properly said, that a Tree grows *Sponte* of its own accord. But the word seems to be more general, and to be opposed to that which is against ones will, or to that which is not done save by an external Agent, and contrary to Natural Inclination. And therefore, as it is attributed to other actions which are performed by an internal Agent, no external Cause concurring, so also it is attributed to Natural Generation. Whence *Virgil.*

Such Fruit he plucks as the free ground affords,
And gentle Trees bear of their own accords.

But in more special manner it is attributed to those Generations, the efficient cause whereof lies concealed in the thing it self, and is not so manifest to the senses, and when that which is Generated breaks out of its own accord as it were without Seed. Of which *Virgil.*

For some things grow even of their own accord without mans Labor. And,
Such things as of their own accord do grow.

Equivocal generation

It is vulgarly called *Equivocal* Generation, *viz.* Because the cause of such Living things is not thought to be of the same kind with the thing ingendred

what things are Generated of their own accord.

But what things they are which be thus Generated of their own accord is a question. It was an old Opinion, that all Brutes, Yea and Man himself, did at first grow out of the Earth. Which *Plato* teaches in *Menexenus*, as also other Philosophers much Ancienter then *Plato*: after whom followed the Poets in this Opinion. *Lucretius* hath these Verses.

Hardly small Creatures now She makes at last
Who all things made and Beasts with Bodies vast.
It is not therefore without Reason good
The Earth should bear the Name of Mother-hood.
For she mankind out of her Bowels Spun,
And all the Beasts that on the Mountains Run
Her teeming Womb did at fit Season Bear,
And many fashion'd Birds that flie i'th' Air.
But since 'twas fit that She some end should make
Of teeming Labors, and her Quiet take;
She now leaves off like Wife worne out with Age.

And Juvenal, *Satyr* the 6.

For in th' Earth's Non-Age, under Heav'ns new Frame,
They stricter liv'd who from th' Oakes Rupture came,
And Clay-born had no Parents.

And *Virgil* in the Second Book of his Husbandry.

When first all Cattle their Beginning had,
When of the Earth mankinds hard race was made.

But these Opinions had their Original from the History of the Creation of the World. For having doubtless hard somwhat thereof, from the writings of Moses, they turned the truth into these Fables; and since in the Creations History it is said, that God commanded the Earth should bring forth the Living Creature in general after its kind, the Beasts and Creeping Things, with Cattle according to their kind, and that God made Man of the Clay of the Earth; (but they in the mean while knew not the Creator:) they thence invented this same Spontaneous Original of things out of the Earth. This Opinion is also by some attributed to *Avicenna*. But it is not credible that *Avicenna* so great a Philosopher should follow so Fabulous an opinion. *Avicen* indeed writes *Lib.* 15. *de Animalib. Cap.* 1. *As men might cut themselves off from Generation, either by their own free will, or by Pestilential Air and so come all to die, and then if a man should be made he would Generate, and so the*

whether Avicenna held that Men could grow out of the Earth.

kind

kind would be renewed: and making and engendring would mutually assist one the other, in preserving the kind. But the sence of those words is this: if all Men should perish, either voluntarily, forbearing to Generate, or Slain by Pestilence, if after the Death of all Men a new man should be made, which way soever, whether by Gods Creation or any other means; he being a new man cannot be thought to want the power of engendring other Men like himself, by which the kind might be maintained.

The efficient Cause of Living things Generated of themselves

Now concerning the original and efficient Cause of such living Things, Authors do very much dissent. *Cardanus Lib. 9. de Subtil.* saies that such things as are said to be Generated of their own accord are Generated by Fortune and Chance. But therein he is out. For Chance and Fortune have no hand in Natural things, and whatsoever things are made by Chance and Fortuitously, they are not alwaies engendred of the same principles and after the same manner. But things which grow up of their own accord are alwaies bred of the same Principles, and after the same manner, and have certain efficient Causes, which also act for a certain ends sake, and produce certain effects. So, of Horse-Dung Beetles are bred, and not Earewigs; out of Cheese Mites, and other kind of Worms out of flesh, and in general, alwaies things determinate breed of such and such things; Yea, and they are born at a certain Season too; and the kinds of flies, Ear-wigs, Worms, Beetles and Butter-Flies do all spring and perish at their certain Seasons. And although as *Cardanus* Objects, in sundry places on the Earth, in the Waters, in dead Carkasses and elsewhere, we see the same things bred: yet they are Generated of a determinate matter, which may be found in divers places frequently. And although it may happen, that the matter which is fit for the Spontaneous original of things may in some places be collected by Chance: yet that matter is determined, nor are living things made thereof by Chance, but the next efficient is determined, and alwaies acts after the same manner. Nor matters it that such things as arise Spontaneously are less perfect (an Argument whereof they take to be their not Generating) and therefore cannot have the notion of an end, and so seem to be made by chance. For though compared to others they are somwhat imperfect: yet in respect of their own essence they are perfect, are Nourished, Augmented, Moved, and perform operations befitting their species. But that conceit of theirs is false, when as they imagine such things do not Generate; since even the very least and most ignoble of these kind of Creatures do couple and Generate, as *Aristotle* teaches every where, and especially in his *5. de Histor. Animal*: and Experience also it self doth testifie as much. And although in comparison of other Creatures they seem ignoble, yet are they necessary for the perfection of the whole Universe, as shall be said anon from the *Exercitation* 250. of *Jul. Cæsar Scaliger*: and that *Avicenna* wrote well when he said it was better Lice should be bred, then that putrid matter should remain in that condition, is the Opinion of Learned men, who acknowledg a rare piece of workmanship even in the structure of a Louse. For if in the first place we consider the prime Work-Master of all things, he that he might discover his infinite Wisdom and Omnipotency, had rather that living Creatures should be multiplied in the world, then corrupt and putrified matter void of Life; and it is his pleasure, that the bodies of more perfect living Creatures, when they are corrupted should not turn simply to putrid matter, but into more ignoble Animals. Hence, from the parts and Excrements of Animals, from Plants and their fruits sundry sorts of living Things do proceed, and from such and such determinate Things such and such determinate Creatures arise and no other. So thought and wrote *Jul. Cæsar Scaliger*, who *in the forecited place* thus writes: Man was made for God, the world for Man. And soon after: Man is the Prince of Animals. Now man should not have been Prince, if he had not been made as he is, *viz.* in the middle. Nor could he be in the middle, unless betwixt extreams. They were therefore made for the Mediums sake. Now if any of the extreams, or of those things which are seated betwixt the middle and the extreams, were wanting, there would be a vacuum amongst the forms. Which would be a greater fault in Nature, then a *Vacuum* in Quantity without a Body. For what is more absurd then a middle without Extreams? which *Austin* also taught long ago, *de Civitate Dei Lib.* 12. *Cap.* 4. It were Ridiculous (saith he) to imagine that the faults of Cattle and Trees, and other Mutable and Mortal things, which want either understanding

or Sense or Life, should be damnable: since those Creatures have received that manner by the appointment of God, that by giving way and succeeding they might accomplish the lowest pulchritude of times, in their kind, agreeing to those parts of the World. And a little after: the comlinesse of which order therefore doth not delight us, because we according to this our mortal condition being Woven in as a part thereof, we are not able to discerne the whole, to which those particles which offend us do very aptly and decently agree. *And again*: Nature considered in it self and not with reference to our commodity or discommodity, gives Glory to its Work-Master.

Whether things generated of them are produced only by the common Cause.

Others though they do not hold that such things are bred by Chance or Fortune; yet they conceive they have no other immediate Cause efficient, but only the common and remote one, in which opinion is the *Conciliator*, who *Differ.* 29. doth make this difference betwixt other Living Creatures and those which breed of themselves, because the former besides the Universal agent, *viz.* The Heaven, do also require a particular one, since the Sun and Man Generates a Man; But the latter want an immediate Cause, and are produced without a particular agent. And the Name it self seems to say as much. For since they are said to arise of their own accord, that seems to hint, that they have no external immediate efficient Cause distinct from themselves: for else they would not be said to be Generated of themselves. But in very truth, there ought alwaies to be a proportion betwixt Causes and Effects, that Universal Effects may have Universal Causes, and Particular Effects Particular Causes, and General General, and Special Special. And if it were not so, no demonstration could be made; which is not made by the immediate Cause, and so no demonstration nor science can be had of such thing as are generated of themselves. Moreover, the common and remote Causes are all external and manifest. But that such things as grow of themselves do arise from an internal Cause lying hid in the matter, we shall shew anon sufficiently. Moreover, since there is a great variety of things which breed of themselves, and differences, and certain sorts, they verily cannot all proceed alike from one common Cause, but to every sort its next special Causes must be assigned. And that those common Causes do not suffice doth hereby also appear, that which way so ever they turn themselves who defend this Opinion, they cannot disintangle themselves. Whence they are divided into sundry Opinions concerning that remote Cause.

Whether they receive their Soul from God.

Scotus held that the Souls of these kind of Creatures do proceed from the most high God immediately. But the Generation of al living Things is Natural. And therefore a Natural Cause ought also to be sought out; nor must we presently run to God, who having created and constituted Nature, doth now produce nothing immediately and miraculously. And since the original of Plants and other brute Animal is from their Parents by means of Seed, but not from God, save as a remote and universal Cause, shal God be the immediate Cause of such Ignoble Animals? Nor do the two Reasons which *John Duns Scotus* brings for his Opinion any waies prove that God may rather be said to be the Cause of these Spontaneous things then of such as arise from Seed; as *Fortunius Licetus* doth prolixly examin his Opinions, *Lib.* 1. *de Spont. Vivent. Art. a Cap.* 77. *ad* 84. Nor do I think fit to spend time in a plain Case.

A place out of Luther concerning the generation of these kind of Creatures.

Luther upon *Genes. Chap.* 1. *verse* 20. thus writes: If you ask by what virtue this Generation is caused, which they term *Equivocal*, *Aristotle* answers, that the putrified Humor is cherished by the Suns heat, and so a live Creature is produced: But I doubt whether this be a sufficient Reason. For the Sun heats, but generates nothing, unless God say by his divine power, let a Mouse come out of that putrefaction. A Mouse therefore is also a Creature of Gods making &c. and a little after: therefore we do here also admire the Creature and work of God. And the same may be said of Flies.

From this Opinion *Johannes Gallego de la Serna* the Spaniard dissents not, *de Princip. Generat. Lib.* 1. *Cap.* 3. who holds God alone to be the principal cause in this kind of Generation, and writes, that though every Univocal cause cannot produce its individuals, unless God as the first cause concur with its action: yet God concurs with each after a different fashion, according as the Generation differs more or less from the Equivocal kind, in which God alone operates as the principal Cause.

cause. And in *Chap.* 4. he adds, that these weak kinds of living Creatures do need a more vehement concourse of God then those that have a greater ability to beget their like.

How God concurs to the generation of things.

But the most good and great God, (after he had made Nature, which is his ordinary power) is not alone the next and immediate efficient cause of any thing, but by his universal Concourse conserves all Natural things, and regulates their Generation; which concourse of his to restrain to one thing, (especially being more vile and ignoble) more then to another, and to hold that he is more vehemently and painfully busied in some imperfect base thing, then in others that are more perfect and noble, is very absurd. *Scaliger* saies far more rightly and divinely, *Exercit.* 1. *That power* (saith he) *of God took no more pains in building this universe, then in making the basest tree: nor did it express more subtilty when it made that by its Virtue the Load-stone should have a cause in it self restraining the efficiency of attraction, then when he gave to the first matter the form of Air, that it might ascend. For in his works there is the greatest Equality.* And in 2. de Plantis. *God, neither idle nor laboring; neither in nor without worke; but without worke the Head of the work, the beginning, the Middle, the End, the whole; and that in one word I may Express all, Compass all, Transcend all:* He himself, *by whose most simple and indivisible understanding of himself all the Worlds were made: so that all have their own End and Order.*

Nor doth *Franciscus Suaresius* think any righter, Who, *in Disput.* 18. *de Causis Proxim. Effic. Sect.* 2, *Num.* 33. writes: that the Heaven indeed by its own proper Virtue cannot make Souls; yet that it makes them by the power of God, as the Author and general provisor of Nature, who by his greater assistance can supply whatever virtue is wanting in the immediate Causes. But the answer is the same which was given to the other Opinion. For since God created all things very good, he also furnished them al with necessary forces, and consequently here is no defect, no weakness, which need to be supplied either from Heaven, or by the extraordinary assistance of God.

Others therefore take pains indeed to find out this immediate cause, but all unhappily, whiles they seek the same out of the matter, and not in the matter, and define Equivocal Generation to be that in which the efficient out of matter which came not from nor out of it self, but is of a quite different Nature, generates a thing specifically unlike it self and its own form. But none of them hath been able without Absurdity to say or shew what that efficient is, and how it could Generate a thing specifically unlike it self, and its own form.

Whether the forms of these Creatures is made by Intelligences.

Avicenna held that an Intelligence Subordinate to God, whom he calls *Colcodea*, doth produce the Souls of these things. But it is not yet proved, that there are such Intelligences from which things Natural proceed. For from God alone as the first cause of all things, and Nature, all Natural things proceed. Nor is Creation to be attributed to any other thing but God Omnipotent. But the immediate efficient Cause of Generation ought to be like, either in sort, or in the next kind, to that which is Generated. And therefore these Spontaneous live-Things cannot arise from a Cause of a quite different kind from themselves, since they are Natural Bodies.

Whether they are generated by the Heaven.

Thirdly, Others hold the immediate efficient Cause of these Bodies to be the Heaven. But this Opinion will not hold Water, more then the other. For in the first place, the Heaven is the common cause of all things Sublunary, as Subservient to their Generation: and therefore it cannot be said to be only the immediate cause of these Spontaneous Creatures, for the Heaven after its fashion advances the Generation of these kind of Creatures, and of such as engender one another, all alike; nor can any Reason be assigned, why it should rather advance the Generation of Spontaneous things then of others. For if they will run to Heaven for want of an immediate Cause, we shal declare sufficiently hereafter, that it is not wanting neither, in the Generation of these Spontaneous Creatures. Moreover, although they that hold the Heaven to be the Cause of this Generation do sundry waies endeavor to declare the same: yet none of them do sufficiently explain the matter: For some, as *Averroes*, do hold that the heat of Heaven is the efficient Cause of these Creatures: or that these Creatures are produced by the Heaven, by help of its heat. Others (as *Albertus Magnus*) do hold that the light of Heaven is the immediate Cause of the

Original

Original of things; others, the motion of Heaven, as *Thomas Aquinas*; others, the occult influences, as *Fernelius*. But which way soever they turn themselves, they help themselves not, but are still pressed with the same difficulty. For the Heaven which way so ever it acts, as was said before, is but a remote and universal Cause. But every effect requires an immediate Cause, and a special effect a special Cause. Moreover, Heat, Light, Motion, and occult Influences are accidents. But no substance, such as the Souls of these creatures are, can be produced by an accident. Some indeed do hold, that Heaven is not only an universal Cause, inasmuch as it affects all Sublunary things, but also a Particular, in as much as by a Peculiar Virtue it concurs mediately or immediately to the generation of all things. But neither is the knot thus loosed. Indeed I grant, that after its fashion the Heaven doth also particularly concur to the making of all things Sublunary, and that not one face of Heaven nor posture of the Stars, and influence thence proceeding, and seasons thereon depending, but sundry, are necessary for several Plants, when they grow, when their flowers ripen, when their fruit comes forth; and that some things spring at certain positions of the Heaven, and die away at other positions, and that doubtless there is a Peculiar Sympathy betwixt some certain sorts of things and some Stars. But the question is whether the heaven gives the forms which constitute those species: which we deny, and hold that the Heaven by its influx doth only stir up some first qualities in the Air, and also by an occult influence excite the forms of living Things, and cause them to buckle themselves to their proper operations. And so, as the Heaven in Univocal Generation so called, whiles the Sun and a Man do generate a Man, is not the next and immediate, but the remote and mediate cause: so also, in this Spontaneous original, it is not the immediate and next, but the remote and mediate cause. Which in Plants and Eggs is hereby manifest, in that even the heat also raised from Elementary Fire doth often perform as much. So the heat of a Stove can in the Winter cause, that forms which lie hid in Seeds will begin to rouze themselves up and sprout. After the very same manner Flesh also in the Winter time kept in an hot place will putrifie and breed Worms, as wel as in Summer. And as the Dugs of Virgins whiles by their heat they hatch the Silk Worms Eggs do not give a form to the Silk-Worms, nor the heat of the fornace doth not give to Eggs the form of Chicken: even so the Heaven doth not either by its heat or hidden influx give the form to these Spontaneous Creatures; but as it cannot ingender a Man without a mans help, so, unless there lie hid in the matter a seminal principle it can engender nothing therefrom. For the Heaven indeed may hold its course without inferior causes: but in the things themselves below it alone can ingender nothing without the concourse of inferior causes, they being in every Generation the immediate and principal agents.

Whether the Heaven be also a Particular Cause.

Whether these spontaneous Creatures do spring from heat.

Alexander, *Olympiodorus*, *Cardan* 9. *de Subtil. Libel. de Animal. quæ ex putred. Oriuntur*, (whom *Cæsalpinus Lib.* 6. *de Nat. Rerum, Cap.* 21. and others do follow) hold that the Spontaneous Generation of living Things doth proceed from the warmth of the Ambient Air, either as from an instrument of the Subcœlestial Nature, or as from a primary efficient cause. But since heat is an accident, it cannot act beyond its own forces, so as to produce a substance. Moreover, heat is only the instrument of vital actions; and therefore no primary agent.

Whether they proceed from the Soul of the world.

Others, as *Philoponus*, *Themistius*, and the *Platonists* most of them, do suppose that the Soul of the World is the efficient cause of these Spontaneus living Things. For so *Themistius* 1 *de Anima Cap.* 24. *That there is* (saith he) *an only and Universal Soul of the world, which gives to all living Bodies their Soul, or life if you will so call it, which is nothing but a certain vital and generative faculty, passing through all things Natural, those Animals which are Spontaneously bred of putrid matter do most clearly prove.* And *Marsilius Ficinus*, *Lib.* 4. *Theolog. Platon. Cap.* 1. writes, that the Soul of the World every where through Land and Water contains in it self spiritual and Vivifical Seeds, and generates of it self, wherever Corporeal Seeds are wanting, also it cherishes the Seeds left by Animals, and of a putrid Grape-seed it can generate a various orderly and precious Vine-Tree; and wherever a generator is wanting, and accidental qualities do only shew themselves, it performs generation, and undergoes the office of a generative substance. But in good deed, we have elsewhere shewed, that there is no Soul of the World. For though in Animals

sundry

sundry actions proceed from one Soul: yet it is not proved, that the world is after such a manner one as an Animal is one. And if the world indeed had a Soul, it should be only an universal cause, not an immediate, nor could any Reason be given why Spontaneous things should rather proceed therefrom then non-spontaneous: and of necessity a cause must be which in Spontaneous things should determine the same to this action, as there are specifical causes in the Generation of other living Things. Nor was it therefore to be constituted, that it might supply the defect of a next Cause, in things of Spontaneous original. For we shall hereafter shew that such a cause is not wanting in the Generation of those things. And how can so many sorts of things Spontaneously generated proceed from one Soul?

whether from the Soul of the Earth.

The Opinion of *Cicero* and *Seneca* differs not much from the foresaid opinion, who attribute that which the Platonists ascribe to the Soul of the World, unto the Soul of the Earth and Water, or of the Terrene Globe especially. For so *Cicero*, 2. *de Natura Deorum* writes: And if so be those things which are contained in Plants of the Earth do live and grow by the Art of Nature, verily the Earth it self is contained and held in by the same force and Art of Nature: forasmuch as she being ful of the Seeds of things, engenders al things, and pours plants out of her self, embraces, nourishes and encreases them: and she her self likewise is nourished by the upper and extream Natures. And *Seneca*, 6. *Quæst. Natural. Cap.* 16. 'Tis evident saith he, that the Earth hath a Soul. I do not mean that Soul only whereby she holds her self, and joyns her parts together, which is even in Stones and Dead Bodies: but I mean a vital vigorous Soul which nourishes all things. If She had not this Soul, how should she infuse Spirit into so many Trees which have their life from nothing else, and into so many Herbs? How should she be able to foster so many Roots, so different, in so various manners buried in her, some creeping in her surface, others growing deep downwards, unless she had plenty of Spirit, which generates so many and various things, and affords nourishment to the same? And *Marsilius Ficinus*, *Lib.* 4. *de Immortal. Animæ Cap.* 1. We know for a certain (saith he) where nutrition and augmentation follows Generation, there is Life and Soul. But we see the Earth by her own Seeds Generate, nourish and cause to grow innumerable Trees and living Creatures. Also she cause Stones to grow, as it were her Teeth, and Herbs as it were her hairs, as long as they stick fast by their Roots, which if they be plucked up and rooted out of the Earth they do not grow. Who will say, the Womb of this Mother is void of Life, which of its own accord brings forth and nourishes so many Children; which sustains its self, whose back brings forth Teeth and Hairs? The same may be said of the Body of the Water. The Water therefore and the Earth hath a Soul, unless perhaps some man will say, that those living Creatures which we (because they seem to have no Seeds of their own) say are generated by the Soul of the Earth, are not bred of the said Soul, but from the influences of Heavenly Spirits.

But as this Opinion differs not much from the former, so after the same manner it is easily refuted. It is truly manifest that much Air and Spirit is contained in the Bowels of the Earth. But that the said Air and Spirit is the Soul of the Earth cannot be proved. Nor are those Spontaneous living Things we speak of Generated only in the Earth and Water, but also in Animals and Plants, as sundry sorts of Worms. And if in the Earth there were such a Soul, she would not be less noble then her effects, but would also be nourished, grow, and exercise Senses. Also no necessity forced them to suppose such a Soul in the Earth. For it is most known that all other living Things have their Seed from whence they are Generated: and we shall hereafter shew that Spontaneous things are not without their immediate cause neither. And if there were indeed such a Soul, since it would be but one, it could not produce so many different sorts of Creatures, but of a determinate specifical Effect a determinate Cause is requisite. And though the Earth as a common Store-House doth afford nourishment to Plants and certain Animals: Yet it follows not, that she gives them their Souls. The Plants are first constituted by their Souls, before they draw nourishment out of the Earth. Nor doth the Earth of Her own substance afford nourishment to Plants, but only as a Store-House, in which are many mixt Bodies, which prove nourishment for Plants.

Erastus

whether Plants Spring up of their own accord by reason of a faculty implanted in the Earth.

Erastus dissents not much from this Opinion, *Part. 2. Disput. Contra Paracelf.* who makes the divine power implanted by God in the whole matter at the first Creation the Author of such effects. But he doth not prove that ever God gave to the whole matter such a power. God produced Plants and Animals out of the Earth and Water, and put into all of them their forms, and commanded every sort of Plants and Animals to multiply themselves, and to bring forth Seed and Fruits according to their kind: but that God gave the whole matter out of the sorts and kinds of things a power to produce Living Things, is no where read in Scripture. But whether this Opinion may any way be tolerated shall be expressed *in the following Chapter.*

whether from a spirit produced from Heaven?

Franciscus Picolhomineus, concerning things springing from putrid matter, Chap. 3. held that living Things which spring of their own accord without Seed do arise from a spirit produced out of Heaven. For thus he writes, among other things: *Towards the Generation of Animals which arise out of putrid matter, the Sun or Heaven performs after a sort the office not only of a common but also of a proper cause, in asmuch as by its light and motion is constituted the spirit which immediatly forms Animals and gives them life, which answers by way of proportion to that Spirit by which Seeds are made Fruitful, and the Child is formed. Which Spirit, although it hath its vitality from the eminent life of Heaven; yet that it may produce this or that life, it hath from Heaven, as it is Heaven, but as it is received in a determinate matter with a a determinate measure, suitable to the determinate sorts of living Things.*

But these things are said, not proved, nor do they make appear that the Heaven lives, and that such a vital Spirit is sent from the Heaven into these lower Bodies. And if this same spirit be the immediate Cause, what needs a determinate matter? Which being necessary, we should therein rather seek the Cause of Spontaneous living Things. But the Heaven can be only a common Cause, as it is in those things which are generated of Seed: and because it hath only one uniform faculty, it is no more disposed to breed a Flie, then a Wasp, or Flea, and therefore it cannot be the proper cause whereof we treat in this place.

The efficient Cause of Spontaneous live things lies hid in the matter.

Others therefore, seeing it was in Vain to search out of the matter for the efficient Cause of such live Things, they have sought the same in the matter and that rightly. Nor could that move them, of which we spake *in the foregoing Discourse,* that some conceive that the form and matter are internal causes, the efficient and the end external. For it is false, that the efficient Cause should be alwaies reckoned amongst external causes; but the form it self, as *Aristotle* testifies, is many times one and the same with the efficient. But some have sought this Cause one way, some another.

whether putrefaction be the Cause?

The most do hold putrefaction alone to be the cause of the Generation of Spontaneous live Things. And with what Authorities they endeavor to prove this their Opinion, I regard not, in case I prove it to be False. Which by this only Reason may be proved, in that the whole Nature of putrefaction consists herein, that it is the corruption of a mixt Body, consider'd as such. And if any thing else proceed from putrefaction, it is by accident. Moreover, experience shews that many Plants and other things are generated of their own accord without putrefaction. And of worms sundry flying insects are bred without putrefaction. And in *Cyprus* in the Brass Fornaces *Pyraustæ* or Fire-flies are bred without putrefaction. And therefore we must hold concerning other living Things, that they are not bred of putrefied matter, although somtimes in a putrid thing, and out of the part thereof which putrifies

Or from Concoction

Others seeing that putrefaction could not be the Cause of these Creatures held that concoction was the Cause. But in good truth, Coction is only an alteration and perfection of the Temperament, and induces no change save in qualities, and therefore of it self can produce no substance, but tends only to perfect a thing already constituted by its form. Or if any Coction precede the Spontaneous Generation, it it only a Previous disposition of the matter, which being attained, the Latent form begins to rouse it self, and begins to form its own body. And although *Aristotle 5. de Histor. Animal. Cap. 19.* writes, that it is common to all Worms, and such Animals as spring from Worms, to receive the beginning of their Generation from the Sun or Spirit; yet that is not to be understood of the communication of the Soul, but only of the disposition of the matter to receive the form under the notion of a Soul, which is caused by heat.

Some

Some again, not being likewise able to find a sufficient cause of this kind of Generation in putrefaction do again fly to the power of the Heaven, and write; that this Generation is made out of putrefaction, by force of the Heaven and Stars exciting the putrid heat, and directing that which is unnatural to the Garkass to become Natural and a certain primary efficient, to induce the forms of some peculiar Animals out of the subject matter. But this will not help a bad Cause. For in the first place, not the heat of the Stars only, but any other heat will serve to raise putrefaction in plants and Animals. Moreover 'tis a begging of the Question to affirm that forms are drawn out of the power of the matter. Moreover they must shew, how heat which is a quality can act beyond its abilities, and not only as an Instrument of a more noble agent, but as the chief efficient, produce a substance, and that such an one as the Soul of an Animal. *whether from putrefaction and the Heaven?*

Chap. 2. *The true Opinion concerning the Spontaneous Original and Efficient Cause of these Living Things.*

SInce therefore the Generation of Spontaneous living Things cannot proceed from the Causes hitherto specified (concerning which thing *Licetus* treates largely and laboriously in his whole 1 Book *de Spon. Vivent. Ortu.*) another cause must be sought after. For the right finding whereof, we must first enquire what is the difference betwixt the Generation of living things which breed of their own accord and of such as arise from Seed, and what living Things are properly said to be Spontaneous. And we must know in General, that those things are said to be generated Spontaneously, which are generated without any evident and manifest cause. So *Hippocrates* in the 1 Book of Aphorismes, Aphorisme 2. calls those fluxes of the Belly and vomiting Spontaneous, which happen without the use of Medicaments, and *Lib.* 2. *Aphoris.* 5. he calls those wearinesses Spontaneous, which proceed not from motions and exercises, but from some hidden fault of Humors. So also Plants which grow without the care and labor of the Husbandman are cal'd Spontaneous. Of which *Virgil* in his 2 Book of his Husbandry.

Nature on Trees doth different Births bestow;
Some of themselves without Mans aide do grow,
And round the fields, and crooked Rivers come,
As Limber Osiers, Poplars, tender Broom,
And Grey-leav'd Willows.

And Animals which spring from Copulation of their Parents are not cal'd Spontaneous; but such as are generated without the help of Parents are cal'd Spontaneous. Thus *Pliny Lib.* 9. *Cap.* 51. writes of Frogs: *'Tis wonderful how after six months life they turn to slime, no man discerning; and again in the Spring they are regenerated after the same secret manner, and this happens every year. Also Limpins and Scallops do breed of their own accord in sandy places.* But yet from the premises it is not sufficiently apparent, what those living Things are which be said to spring of their own accord. For although many plants grow without the Care and Labor of Men: yet they do not all grow without Seed; since many sow themselves, and cast their Seeds into the Earth, or Propagate themselves by Roots. We are therefore now to enquire the difference betwixt things that are generated of their own accord and such as are not.

Fortunius Licetus, Lib. 2. *de Spont. Vivent. Ortu, Cap.* 2. holds, that the Spontaneous Original of living Things proceeds from an Occult Principle which lies hid in the matter wherein the Generation is to be made, and therefore from a principle internal to the thing generated, though Latent. But the Spontaneous original of things is not thus sufficiently differenced from the non-Spontaneous; since also in the non-Spontaneous original of living-Things the hidden principle of the thing to be generated lies lurking in the matter or Seed. For the principle of generation is equally hidden to the sense, in an head of Garlick, an Onion, or a Corn of Wheat, as in Horse-Dung, whence the beetle arises. This rather ought, I conceive, to be *The opinion of Fortunius Licetus.*

The true difference. accounted the difference: that such things as are not Spontaneously generated do proceed from a Seed, or Bulb, or some other thing answering to Seed, manifestly produced by a plant of the same kind: but such living things as Spring of their own accord are produced without a manifest generator of the same sort. Truly when generation it self is made, or rather the formation of an organical Body, the generation of a Spontaneous living Thing differs not from that of a non-Spontaneous. For in both the motion and the formation of the Body is made by an agent, which lies concealed in the matter. But herein they differ, in that, before the parts begin to be formed, the Soul in its essence, and as such, and as it performs the office of a Soul, is in the Seed or matter in the non-Spontaneous generation: but in Spontaneous generation, although the Soul be in some sort in the matter of which the living thing is made; yet the Body of a Carkass, or what ever other matter, doth not participate the same under the notion of a Soul; because a Carkass is not properly animated, nor yet under the notion of an efficient cause, because as yet it is dul and Stirs not.

The differences of Spontaneous living Things. Howbeit, in this thing, there is stil no small difference. For some things are really engendred of matter specifically different; as the Beetle of Horse-dung, worms of Cheese or flesh; but some things seem only to the sense to be generated without seed, and of a thing specifically different, when as indeed they are made of seed, or of somwhat answering to Seed: as some Plants are said to grow of their own accord, after Rains or Inundations of Water, when as in truth they are made of Seeds mingled with Rains or Waters. So of Swines dung, Carduus, and Sow-Thistle and other Plants do grow, not as Beetles do out of Horse-Dung, or Worms out of Cheese, but because some of the Seed of these plants unchanged by digestion are voided afterwards with the Dung. Which two differences of Spontaneous Generation must needs be observed.

Places of Aristotle where he teaches that all things are Generated by an univocal Agent. And though there be some difference of Spontaneously Generated live Things: yet they all proceed from an univocal agent and not from an Equivocal: which *Aristotle* teaches in many places (nine of which *Fortunius Licetus* quotes) in al which he tels us, that all substances are generated by an efficient actually of the same Nature univocal. The First is, 1 *de Generat. et Cor. Text* 30. The Second, 1 *Magnor. Moral Cap.* 10. The Third, 1 *de Part. Animal. Cap.* 1. The Fourth, 7 *Metaphysic. Text* 22. The Fifth, *in the same Book, Text* 30. The Sixth, *in the same Book Text* 31. The Seventh, *in the same Book, Text* 32. The Eighth, *in the* 12. *Metaphys. Cap.* 13. The Ninth, *in the same place, Text* 18. all which may be seen in his works. We shall only produce one or two. For *Aristotle* in 1 *de Generat. & corrupt. Text* 30. 1 *Magnorum Moralium, Cap.* 10. 1 *de Part. Animal. Cap.* 1. writes, that even those things which are said to breed of their own accord have a like efficient cause preceding, as well as things produced by Art. And *in the* 7. *Metaphys. Text* 22. and *Text* 32. he writes expresly, that it is proper to a substance for to have necessarily another like substance actually preexisting, whereby it may be Generated. And *in the* 12 *Metaphys. Text* 13. and *Text* 18. he therefore rejects the Platonical Ideas, because all things both Natural and artificial have like univocal causes by which they are produced.

How spontaneous living Things are generated by an univocal generator. Although therefore it is to be granted, that even the Spontaneous Generation of living Creatures is after a sort univocal; Yet I shall not deny that Generation is an Analogical kind; and that Univocal Generation is more evident in non-Spontaneous, then in Spontaneous living things. Which *Aristotle* himself seems to hint, who in the place but now alleadge, 7 *Metaphys. Text* 30. saies that all things are made after a sort by an Univocal agent. And indeed the Nature of the Generation of Plants which proceed from Seed properly so called, (such as that is of non Spontaneous live Things, as also of those things which arise from a latent seed) is different from that of those live things which are most properly said to arise Spontaneously and Equivocally. For in the former, the Seed of which they are Generated, *viz.* Herbs, hath actually a Soul in it already: but in these latter, the matter of which the living thing is Generated hath not actually in it the Soul of the thing generated; suppose a worm. Yet the form lying hid in the matter is apt to be turned into a Soul, so as to communicate it self to the matter, in notion of a Soul, and thereout to frame a living Body. Whence that difference betwixt *Seneca, Scaliger*, and *Licetus*, concerning the Seed, may easily be compounded. For

Seneca

Seneca 3. *de Beneficiis Ch.* 29. and *Scaliger* in *Theophrast. de Plantis Lib.* 1. *Ch.* 5. teach that al things have their Seeds. But *Licetus, de Spont. Vivent. Ortu, Lib.* 4. *Cap.* 2. denies that al things have their Seeds, and holds that some things are propagated by no Seed properly so called, though they have somwhat answering to seed by way of proportion. For an answer may be made out of the very words of *Licetus*; *viz.* Seed is taken properly, and improperly. Seed properly so called is a Body, which as the proper subject contains in it self a Soul, in the first formal act; which comes to pass in such things as are not generated of their own accord: but improperly that may be called a Seed, or at least somwhat answering to a Seed, which hath not indeed a Soul actually, yet containes a principle or form, which attaining a fit disposition of matter begins to exercise the Office of a Soul. Whence, the Carkasses of Plants and Animals out of which Worms are Generated do not contain in them the Seed of Worms, yet they have in them a form, which doth afterward advance it self into a Soul. Mean while this also is true, that such things are not altogether Equivocally Generated as is vulgarly imagined: which appears even hereby, that those living things which are thought to be generated of themselves and Equivocally, are of the same sort with those which are not so Generated: which thing is manfest from Generation it self. For although some things Spontaneously bred do not generate, as Toad-stools, and Vine-Worms, and other vile creepers: yet most of them engender a living Thing like themselves, as Experience testifies. *Theophrastus* writes 1. *de Caus. Plant. Ch.* 1. and 5. and *Scaliger* upon him, that a Plant Sprung of its own accord hath by its Seed produced another like it self. So *Laserpitium* which grew up naturally of its own accord, and a whole Wood of Trees, where never were any before, did produce Plants that bare Seed. Bees bred out of a Bul are fruitful. And *Avicen*, 15. *de Animal. Cap.* 1. doth testifie, that he had a friend who made Scorpions, either by burying the Juyce of Basil, or by some other means, and they afterward generated other Scorpions. And that in a certain City of the *Saracens*, called *Scealikam*, after a great Rain, Silk-Worms were seen to cover the ground many miles together, and every Worm made Silk, and afterwards they flew away and made Seed.

Seed taken properly & improperly

Now that the univocal Agent by which Spontaneous living Things are bred is a Soul of the same sort with that whereby they are constituted in their being, and vivified, *Fortunius Licetus teaches Lib.* 2. *de Spont. Vivent. Ortu, Cap.* 26. For since, as *Aristotle* both in other places and in 1 *Magn. Moral. Cap.* 10 teaches, Plants and Animals arise from Seed as an univocal principle, but the Seed is not univocal to the Animal or Plant to be generated, save as it participates a Soul of the same sort; it seems from thence apparent, that the Univocal efficient from whence Animals have their original which are Spontaneously generated, is a Soul of the same Nature with that wherewith they are enlivened. And questionless the case is plain. For since it is most Natural and proper to the Soul to generate live things; nothing can Naturally procreate living Things which hath not a Soul in it.

The efficient of spontaneous live Things is the Soul.

Now that the Soul of these living Creatures is in the matter, and that we are not to seek their efficient Cause out of their matter, the Generation of Worms out of Flesh doth shew, in which no external Cause helping, unless the heat of the Ambient Air, Worms break out of the Flesh of their own accord.

Now whence this Soul which is the efficient Cause of these Spontaneous Animals doth come into the matter, of which they arise, is further to be enquired into. And although this be a very difficult point, and one of the obscurest in Nature, and it is also hazardous for a man to propound his opinion herein: yet will I freely propound my mind, which if it shall not please all men, yet such as are studious of the truth will acknowledg thus much, that it comes nearer the truth then that Opinion of the Eduction of forms out of the power of the matter, which is an Opinon that paies a man with words, but hath nothing in it to satisfie a studious mind, as is sufficiently declared in the 4. *Chap. of the foregoing Discourse.* And first of all we must hold (which I conceive to be out of question) that nothing can contribute such a matter nor consequently the Soul, unless it be a Living thing, or proceed from a living Thing; and that therefore Spontaneous living Things do only proceed from living Things or such as have lived: which also experience teaches. For it was never yet known, that of the simple Elements, of Metals, Minerals, Jewels, as such, any

whence the soul comes which Causes Spontaneous Generation?

Spontaneous live Things grow only out of Things living.

any Animal or living Thing hath been bred, but every thing of which such Animals are Generated is either a living Body, hath lived, or hath proceeded from a living Body.

How many waies the Soul may be in the matter?

Now to find out the manner of this generation, in the first place we must enquire, how many waies the Soul may be in a thing. For in the first place, which no man denies, there is a twofold act of the Soul: one Essential, called the first Act, and is the bare Essence of the Soul: the other accidental, which is called the Second, and is the operation proceeding from the Soul. And therefore the participation of the Soul is also twofold, the first is the Participation of the simple substance of the Soul, as of a form perfecting its matter; the Second is the Participation of the Soul operating. The Second participation is when Organs are provided for the performance of the actions; to the first there needs only a disposition of the matter, that the Soul may thereby be fit to perform the Office of an Efficient Cause and to form the Body.

A twofold act of the soul.

Essential

Accidental

A double operation of the soul.

A soul may be in a matter & not inform it.

But besides these two manners, there is yet a Third, and the Soul may yet after another manner be in some kind of matter, so as neither to inform the same and vivifie it, nor to perform the proper operations of such a living Thing. So the Seeds of Plants and Animals may be in the Water and in the Earth, and the Soul may be in them, and yet they neither inform nor Vivifie the Water nor the Earth. Hence *Aristotle* said, not without reason, 3. *de Gen. Animal. Cap.* 11. that all things are ful of Souls, while he thus writes: *Now Animals and Plants are bred in the Earth and Water, because there is moisture in the Earth, Spirit in the Water, Animal Heat in the Universe, so that all things are in some sort ful of Souls. And therefore they come speedily to a Consistence, when that heat is comprehended or received.* Which very thing manifestly appears from things putrid, out of which sundry kinds of Worms are every where bred, and in Plants which grow in Common Fields and Gardens where no Seed hath been cast. And scarce any place is so barren but that Plants and Animals will breed therein of their own accord. Now this speech of *Aristotle* is thus to be understood, not that all things do live and are animated; for which cause he did not simply say, that all things are ful of Souls, but in some sort, *viz.* in all things in a manner there is such a like substance, which when all impediments being removed it hath got a fitting matter, it rouses it self and performs the Office of a Soul. For, to live, is not to have and contain a Soul after any fashion; but to participate the same and to be informed by it, and as that which frames and preserves the organical Body. For, as *Aristotle* teaches, Animal heat, and consequently that which hath the Soul adjoyned thereto, is truly in all the lower part of the world, the Air, Water and Earth: but not as their essential part or attribute; since the Earth and Water are of their own Nature cold, and neither of them are informed by any Soul: but as a thing placed in a place or Vessel, *viz.* because the Earth, Water and Air, do contain the Carkasses parts and Excrements of Living Things, in which are Atomes and smal Bodies having Souls in them. And so the Generation of things Spontaneous is then caused, when the Souls (as *Fort. Licetus* speaks) are now by the benefit of heat united and associated to such things in which they were contained only as in a place or Vessel, under the notion of a Cause efficient, forming an organical Body; or as *Aristotle* speaks, when the matter shall comprehend that same heat of Animals and the Soul with it, and shall make it proper to it self; presently by way of Spontaneous Generation that matter receives the Consistency of a living Nature, putting on the Soul in Nature of a Form, which before it contained distinct from its Nature, like a Vessel.

How all things are ful of souls.

What 'tis to live.

The soul is two waies in the matter

Concerning which thing *Fort. Licetus* treats at large, *Lib.* 2. *de Spont. Vivent. Ortu, Cap.* 11. 28. *et Seq.* and endeavors with much labor to prove, that the form and Soul is two waies in the matter, *viz.* as an act and perfection in its proper subject, and then as a thing contained in a Vessel, not belonging at al thereto, or as an accident in the subject. And this distinction is the foundation of his whole Doctrine of the original of these kind of Creatures. 'Tis not worth while to cite here all that he there alleadges. For sure it is, the Fire with its form is in the Iron, is in the hot Water, is in Rain, is in the Earth, and yet doth not inform them. And which is a most clear example, Gold resolved into its smalleſt Atomes is in *Aqua Regia*, and Silver in *Aqua Fortis*; yet so as to retain their forms entire, as appears by their Reduction;

Reduction; yet they do not inform those Waters, but the Form of Gold and Silver is in the Waters, as in a place. The same appears in the Souls of living Things. For the Seed cast into the Earth is therein as in a place, nor is the Earth informed by the form of the Seed. Yea and which is much more wonderful, the Form of a Plant will sometimes remain in dry Wood, as *Virgil* writes of the Wood of an Olive-Tree, in the Second of his Husbandry.

And (Wondrous to be told) an Olive Tree
Out from a dry cut drunk oft springs we See.

Of which we shal speak more at large in *Chap.* 7.

But whether Souls may properly be said to be in a place, and whether all the Souls of Spontaneous Creatures are thus in the things whence they spring, I doubt. Truly if Seed, or a Body answering to Seed consisting of matter and form, may be said to be in a place, as Frogs spawn, or that Seminal Body out of which after Raine Plants do Spring, it is rightly said to be in a place. But whether the Soul it self which is therein, in the Water, or Rain, may properly be said to be in a place, I doubt. But let us thus take the Soul with its proper subject, and let it in this manner be said to be in a place: yet whether after the same manner in a Pine, out of which Ear-wigs, or in other woods whence worms spring, or in Corn whence the Wibbles are Generated, that Soul of the living Creature be present, may be justly doubted. For the Atomes of Gold and Silver consisting of their matter and Form, are in the *Aqua Regia* or *Aqua Fortis*, as in a place: and the Seed of some Plant or Frog, consisting of a Soul and matter, wherein the Soul is as in its proper subject, may be in the Earth or Water, as in a Vessel or place, but by means of the matter or Body wherein it is. But when of Wood or Flesh a live Animal is bred, there the Soul which of it self is in no place, hath no matter wherein it may be as its own proper subject, and in respect of which it may be said to be, in Wood or Flesh, as in a place or Vessel; but the proper subject of that Soul is that same thing or Flesh, wherein nevertheless it is not formally, but only really, nor hath the notion of a Soul, but then begins to be formally, and to be separated from the Wood and Flesh, and to live and exist by it self, and to have the notion of a Soul, and to exercise living operations, when through putrefaction or rather the heat joyned to the putrefaction, that matter is so elaborated that it may become a fit subject wherein the Soul may formally exist.

Spontaneous Generation how manifold?

And therfore as was said before, there is not only one way of Generation of Plants and Animals which are Generated of their own accord. For some are indeed Generated from Seed bred by a living Creature of the same kind, although they seem to be Generated of their own accord. So, after overflowings of water, after Rains and Winds, Plants do sometimes spring of themselves, of Swines dung Thistles and Sow-Thistles are bred. In which there is no other difference betwixt the Spontaneous and non Spontaneous, save that in the former the Seed lies hidden, in the latter it is manifest. And there are Seeds of different Nature. For some unless they be diligently lookt to and manured they lose their Seminal faculty and their Soul. Others although they seem corrupted, yet in a certain Juyce or in some Atomes the Seminal faculty is preserved. Again there are other Spontaneous live Things which are bred without Seed, as when of Cheese, Flesh or Wood, Worms are bred, in which there is no such Seed found as is in the Waters and in the Earth.

The opinion of Fort. Licetus *of the original of spontaneous live things properly so called.*

Now concerning the original of the latter kind, the question is very difficult, wherein to determine any thing is very liable to blame. *Fortunius Licetus*, *Lib.* 2. *de Spont. Viven. Ortu*, *Cap.* 36. holds that the efficient Generating Cause of Spontaneous Animal, is a Soul of the same Nature with that whereby such Animals are constituted in their being, but not quickening nor any waies actuating the subject wherein it is, but lying concealed, as in a vessel, in that Carkass out of which these Animals are Generated: and that the Soul which is in the Carkass is the same with that which did constitute the Animal or other living thing, but impaired, not having the notion of an actuating form, and perfecting that wherein it is, but of privation; since such an impairing deprives the Soul of its Ancient perfection, which was to quicken and perfect its subject Body. For as a sensitive and seeing Soul is an habit in an Animal that is found; but in one that is blind, it being evervated by the marring of the Organ it degenerates into Privation: so also he holds that after

Death,

Death the Soul of an Animal which remains in the Carkass degenerates into Privation, and being weakned it Creates Spontaneous imperfect Animals.

Now how the Soul is cast down from that perfection, he teaches *in the same Book Cap.* 37. and sets down two waies, by which the matter of the Carkass obtains a non-Quickening Soul. The first is; that when the Live-Creature dies, all the heat necessary to life is not abolished, but so much of it remains as suffices to retain the Soul in the Body, as in a Vessel. In which case, he writes, that as it may happen frequently, that together with the weakning of the heat and Death of the living Thing, the substance of the vegetable and sentitive Soul supported by that heat may suffer an Essential Empairement, whereby it may come to degenerate into a more imperfect nature and a baser kind of Soul; so he conceives it may somtimes come to pass, that retaining its Ancient Essence it may put forth its weakned forces. The other manner he makes to be this: because, saith he, while the old living Creature dies, and while the Excrement is driven out of the Body of the living Creature, its Soul yet remaining may introduce a new Soul into the next matter lately bereft of the same Soul, with a smal heat in the first instant of Nature, not yet able to vivifie its subject Body, but may be bred therein as in a Vessel, somtimes of the very same sort with the generating Soul; but most frequently imperfecter and Baser: both because of the imperfection of the matter, which cannot receive so perfect a Soul, as also by Reason of the Infirmity and Debility of the forces of the Soul Generating, which in the Death of the former Animal either perishes, or is very much weakned, that it cannot engender one like it self, but is able to produce one inferior to it self. Of which he treates at large to the 39. *Chapter*; wherein at last he concludes his Opinion in these words: the immediate efficient Cause of the original of Spontaneous living Things from which they immediately receive their Soul and all Spontaneous living Things are generated, is nothing else but a vegetable or sensitive Soul, abiding in the Carkass, or in the Excrement proceeding from living Creatures, as in a Vessel, lying hid with a weak heat, not actuating the same, nor any waies perfecting it, somtimes of the same sort, or also Numerically the same with that which was formerly in those living things: yet many times of a different sort and a more base Nature, and imperfecter substance; into which with the decay of the Body and heat, the former Soul is degenerated: which Soul in the Carkass or Excrements, proceeding from the former living Creature not quickning its subject Body, it remains therein, not exercising the actions of life, not as a form in its subject, but as in a place, and in a vessel, as it were by necessity of the matter, or at last by the total vanishing of the heat whereby it is supported, it self perishing; or with the augmentation of the said heat and vigour acquired from the Warmth of the Ambient Air, communicating it self to its subject Body, as a form and quickning Soul, and performing the functions of life, as shaping of a Body and generating of a Spontaneous live thing.

the opinion of Licetus *examined.*

But in very good deed, it seems hard to hold, that the former Soul remains in the Carkass; and to affirm it in a man, is most absurd: whereas nevertheless worms are as well bred of the Carkass of a man, as of other Animals. Indeed, *Lib.* 2. *Cap.* 39. *Licetus* excepts the rational Soul, and writes that only the Senfitive and Vegetative Souls remain. But it is only affirmed and not proved, that there are three Souls in a Man, of which the Sensitive and Vegetative may remain after his Death. Yea and in Brutes that same degenerating of nobler forms unto less noble is absurd, and is propounded without Reason. Rather the Constitution of Body and various operations do shew, that Spontaneous Animals which are Generated out of dead Bodies do differ in kind and Form from those Creatures out of which they are bred. Nor doth he shew any Reason, why the Soul of the living Creature should degenerate into the Soul of this creeper rather then another: since we see that every Spontaneous Animal is not bred of every living thing, but certain Animals are bred of certain Bodies. Nor in a blind Man doth the seeing Soul degenerate into a Privation; but in the Eye, because of the disease thereof, Privation of sight is introduced; but the soul it self hath the same perfection it had before, and the disease being removed sees again; nor while a man is blind doth it perform other operations. Yea, and the Soul while it lives informs the blind Eye, although it cannot cause sight therein by reason of its disease. And if the soul should remain in the eye of a blind man, as it doth

in

in a Carkas, contributing nothing thereto, the Eye would be mortified and Sphacelated; but we see the contrary. And although it is true that some part of innate heat and Radical moisture remains in the Carkasses of Plants and Animals, which is not destroied save by Putrefaction and Rottenness which many times happens long after Death; yet that temper and heat of the living Thing doth not remain, and therefore neither can the specifick Soul of the living thing remain; seeing the death of an Animal and of a live Thing is the extinction of that Vital heat, and thereby Souls are separated from their Bodies, but the Soul doth no way suffer any essential impairment (for the Essence of forms is indivisible) whereby it can degenerate into a more imperfect Nature. And when a living Thing is Generated of the Excrements of Animals, it is not credible that the Soul remains in the Excrements; since in the living Body, the Soul was never in the Excrements.

The opinion of the Author concerning the original of Spontaneous Live things properly so called.

But to me it seems more agreeable to truth, that in living Things there are divers Auxiliary and subordinate forms, yet so that one is principal and Queen, which informs the living Creature, and from which the living thing hath its Name, *viz.* The Soul it self of every living Thing; and the rest are Servants as it were, which as long as that superior and Lady Soul is present, do pertain to the disposition and condition of the matter, and therefore they do after a sort inform the said matter, that it may be a fit subject for the specifick form, and they have also actions of their own; yet they do not animate the same, nor do they give it the Name of a living thing; which is the Office of a specifick Soul only. Nor let any man hatefully traduce this Doctrine of subordinate forms as new. Most learned men have delivered the same, and have taught that these forms do constitute the Seminal matter as it were of live Things. *Jul. Cæs. Scalig. Exercit.* 59. *Sect.* 2. writes: *As in the Earth Plants are changed one into another; so above ground they breed Animals out of themselves. And that not out of putrefaction, but cherishing in themselves certain Seeds for Generation.* The same *Scaliger*, *Exercitation*, 190. *Animals* (Saies he,) *Are not bred of putrid Plants, but are the Of-spring of Remaining Vigor which is in them. For it is certain that beans are not putrified, when Animals breed in them.* He also *Lib.* 2. *de Plantis*, *p.* 389. rightly teaches, that it is manifest that Fir-Wood and straw or Chaf have in them the Natural rudiments of Wig-Lice. Also he writes *in the same place*, that it is commonly reported, that of Wig-Lice broken Wig-Lice do also engender. Which he counts unlikely. But that from the same original whence those that are broken did arise, new ones are Generated in the same place. But I see no cause why those rudiments of the Wig-Lice may not remain in those that are rubbed in pieces. *Shegkius* the German, *Aristotle, de Occultis Med. Facult. Lib.* 2. *Cap.* 1. *Page* 103. *in my Edition*, saies, it will be no absurdity, if we shall say that divers forms are in one substance. And afterwards, he proves in Plants, that the specifical form being abolished, there remains not only the temperament, but also the substantial form, and that it is the Author of Occult Faculties. *Zabarella* also, *Lib. de Generat. and Interitu*, *Cap.* 4. writes, that the form of a mixt Body in a living Creature doth not perform the Office of a form, in respect of the whole living Creature, but rather of Matter. But that the Soul being taken away, the same Form of mixture begins to perform the Office of a Form, and to constitute that Body specifically. And this he declares in the same place by an example. Just as, (saith he) if when a King is dead some Servant be made King, he was also before during the Kings Life, but he was not as King; and therefore if any shal ask whether a new King be created or no, answer ought doubtless to be made, that a new King is created, and the King is changed. Even so, at the Death of a living Creature, a new Form is acquired inasmuch as that which was before as a Condition of the matter, being subject to a more noble Form, doth now begin to be a Form to constitute the compound, and to bear Rule. And that which *Zabarella* speaks only of the forms of mixt bodies, that is to be understood of all Forms excepting the Elements, which are necessary to the Constitution of a living Body. And that there are such Forms, is proved before in the *Second Discourse* of this work. Nor doth it import any absurdity, that besides the specifical Forms there should be other subordinate Forms: but as *Zabarella*, *Lib.* 1. *de Generat. & Interit. Cap.* 2. writes, if it be not against Reason there should be two, neither is it that there should be four or an hundred together in the same subject.

There are subordinate souls.

There

whether the subordinate forms are specifical.

There is one who argues here, that subordinate Forms are also specifical. But either he understands not what a specifical Form is, or he cavils Maliciously; and in the mean time he grants in the same living thing divers forms. Verily, There is no form, which by it self considered may not be termed specifical. So the form of fire, where ever fire is, is specifical: but when Fire is in a man, it is not the specifick form of a Man, but the rational Soul is mans specifick Form. He Fights therefore with shadows, and Toies with cavillations, who denies subordinate Forms, and thinks they are not to be distinguished from specifick forms, because they also are specifick. The Form (saith he) of the Earth is under the command of a specifick Form, yet it is in its proper matter, and retains the Nature of a specifick Form, although it be under another Specifick Form. For it is not the Specifick form of that thing to the Form whereof it is subject, but of that matter whose Form it is, with which it abides, comes and goes. But if the form of the Earth be subject to another Form, why shall I not term the same (with *Zabarella*) a subordinate Form? But in a Man to hold both the Form of Earth, and the Humane Form to be specifical, is most absurd. For there is no Natural thing which hath two specifick Forms. Yet those specifick Forms which whiles they are in the living Thing do belong to the matter, the specifical form departing, do become specifical, as the same *Zabarella* teaches, and perform the operations of a specifical Form. So that Form from whence there arises out of a Carkass a Beetle, a Wasp, a Bee, while it is in the Horse, or other living Animal, it cannot be called the form of a Wasp, a Beetle or a Bee; since then it performs not the Office of a Form, but is in place of matter. But when it performs the Office of a Form, it can then multiply it self, and beget its like. And indeed the Nature of a Form is far different when it is subordinate and in the place of matter, from what it is when it becomes specifical. Therefore also subordinate Forms do not give a Name to their subject, nor can I say that in a man there are Worms, in an Heyfer fed with Mulberry Leaves there are Silk-Worms, but at last when the Specifical Form departs, they begin to perform the Office of a specifick Form, and give a Name to the thing.

Whence also that is of no moment which some Object, if the Soul of a Worm were in a Plant, the same substance would be a Plant and an Animal; since the Form gives as well the Name as being to a thing. For the species or Forms of Things, truly, are not simply known or defined by us according to their Essence, but so far forth, as being sensibly parts of the World, by their Bodies and actions they fall under our sense; and a Name is given them, not from their essential act, but from their faculties and actions which they exercise in such a subject. For indeed, the Seed of a Dog doth not essentially differ from a Dog: yet because by the term Dog we do not understand simply the Soul of a Dog with any kind of matter, but a four footed barking Beast, the Form of a Dog in the Seed is not called a Dog, before it have shaped a Body fit for it self. After the same manner, in a Silk-Worm and Butter-Fly, there is one and the same Soul, yet is it not termed a Butter-Fly, til it is changed into a Winged Creature. So also, in a Plant, though there is the Soul of a Worm, yet the plant is not termed an Animal, but the Government of the Plants form ceasing, and another Soul receiving and exercising the Soveraignty, 'tis termed an Animal.

How subordinate forms are in things.

Nor can it be hence concluded (as some object and think it may) that there are in man and sundry other Animals Worms, or that this or that living Creature hath Worms or other live Things in it. For to the Constitution of such Animals, as of all other Natural Bodies, there is requisite not only a Form, but also a matter, and the Form ought to inform the said matter. But those Forms, though they are really in other living things, yet are they not therein in the Nature of forms, nor do they perform the Office of Forms, nor Animate the matter, nor quicken the Body, nor exercise the operations of life therein, but all these things are performed by the more noble and specifick Form, or Soul of the living Thing: but they themselves belong to the disposition and determination of the matter. But when that specifick and more noble Form or Soul goes away, they being stirred up by the ambient heat, and having gained a fit disposition are advanced into the quality of Forms, and communicate themseves to the Body as vivifying Souls, and in the first place they set themselves to shape Bodies fit for them, but afterwards they begin to exercise there-

therein the functions of Life. Yea and the same Forms do lie hid under different external Figures, and so pass into the Theatre of Nature. 'Tis a clear case in the Palmer Worms, in which one Soul puts on divers Bodies, and as *Aristotle* 5 *de Hist. Animal. Cap.* 19. and *Pliny, Lib.* 11. *Nat. Hist. Cap.* 22. saies, there is a various succession of Forms, *viz.* external ones. For the internal remains the same. Which though it may seem to some absurd: yet is it no waies absurd, but it is easie for any one to make observation of the truth thereof. For first of all, of the Egg of a kind of Butter-Fly is made a Palmer Worm; this Worm, according as *Libavius* diligently hath observed, *Singular. Part.* 2. *Bombycior. Lib.* 1. *Cap.* 21. in a months space changes its Skin four times. And who will say, that here the internal form is changed; unless he will say when Snakes cast their Skin that a new Generation is made. Afterwards, it becomes a Silk-worm; where again there is no essential mutation, for a Silk-Worm is no other then a Palmer Worm grown up. And when afterward it becomes a Nymph, there is again no essential mutation, but the internal form only working it becomes a Butter-Fly. Nor doth this happen only in the Palmer Worm and Silk-Worm, but in all Egg-bearers, as for example in the Chick of an Hen. For look as, while by the heat of a Bird of another kind, or also of the Fire, a Chick is hatched out of the Egg of an Hen, there cannot so much as any thing be imagined which should give the Soul to the Chick, unless it had been before in the Egg: so also when by the Warmth of Womens Dugs the Eggs of Silk-Worms are hatched, and there comes out Silk-Worms, nothing can be assigned which might generate the Soul. And that one Soul can assume various Bodies the degeneration also of Plants doth shew, whiles Rie and Barley do turn to Wheat, and Wheat again into Rye and Barley, the same internal Form remaining, and the external only changed.

One Internal form may put on divers external ones

Hitherto also belongs the degeneration of Plants into other Plants; which happens in those Plants whose Seeds are either ambiguous, and contain divers forms in them, yet so as that one Rules and the other serves; unless upon occasion another alteration be made; or whose Soul is disposed to receive divers forms external, as appears in Silk-Worms, yea and Bees too. For as the same essence of a Form doth in them remain under divers external shapes, and first there is a Palmer Worm, then a Silk-Worm, then a Butter-Fly: so also in Plants, there is the same transmutation of the external Form. Which also *Julius Cæsar Scaliger* doth grant; when in 1 *de Plantis*, (saith he) there are the confused principles of divers things in Seeds, as of Rapes, Cole-worts, and others. *Licetus* indeed *Lib.* 2. *Spont. Viv. Ort. Cap.* 14. writes, that a Form upon great mutations of the matter is changed into another species, and depressed into a more inferior degree. But this degeneration upon the mutation of the matter is made not only into an inferior degree but also into a Superior: which experience doth testifie. Wheat degenerates into Darnel; Water-Cresses into Mints; Rape into Radish; Basil into running Betony; the white Vine into the black, and the black into the white; Barley into Wheat, and again Wheat into Barley. If in *Hungaria* they sow German Rye it turns into Wheat. If a Field be somwhat barren, our White Oats (as they call them) degenerate into black; if the same Seed be sowed some years together, it grows more base. And therefore after some years the Husband-men are forced to change their Seed. Contrariwise, if black Oates be sowed in a fat Soil, white Oats will Spring up therfrom. Gilly-flowers, Roses, Violets, do oft change their Colours. Whence *Virgil* writes of Seeds.

The degeneration of Plants.

> *Choice Seeds and with much Labour culled out*
> *Do yet degenerate.*

And *Galen* writes of his Father, in 2. *de Ele. Facultatibus, Class.* 2. *Page* 30. that, when in his declining Age he was delighted with Husbandry he sometimes sowed Wheat and Barley, and pickt out al other kinds of Seeds that were mingled with them, that he might certainly know whether Cockle and wild Barley would proceed from the change of the said grains, or whether they had a proper Seed of their own. He therefore found among the Wheat frequent Darnel, and amongst the Barley wild Barley or wild Oates; and made the same experiment in other Seeds. He therefore found in Lentils also, that they were changed into hard and round

Vetches and Ax-wort, also Goos-grass grow therefrom. If some would now adaies use the like diligence, they should merit most worthy commendations. For so they would not so frequently become laughing stocks for Country Clowns. And this experience would tend more to the gaining of the knowledg of Natural Philosophy, then those Vain speculations, and more base then Ditch-Water, so much in request. I shall say more of the degeneration of Plants beneath. *Chap.* 7.

And so much may suffice to have said of the primary efficient cause of the Generation of Spontaneous live Things. Only this one thing is yet to be noted, that these degenerations are not properly Spontaneous Generations, since they are made of Seed and that evidently: although those Forms, according to the divers disposition of the matter, have the power to shape sundry figures of the external Body. Also the Ambient heat, especially that of the Sun and Moon, do concur to their Generation: but that heat is not the primary agent, but only stirs up the Soul which lies secretly hidden, and prepares and affords fitting matter to the same. And therefore that what we have said of the Spontaneous original of living things may be more apparent, we must speak yet somwhat concerning their matter.

Chap. 3. *Of the Matter of Spontaneous living Things.*

The matter of spontaneous live things.

And indeed the chiefest difference betwixt live Things of Spontaneous and non-Spontaneous original, is in their Matter. For both Animals and Plants which are not Spontaneous do so Spring out of their Seeds, that it is manifest to every one whence they proceed. But the principle of Spontaneous live things lies hidden, and so they arise of their own accord, as it were without any Generator. Yet they have also their principle. For every one of these is not bred of every matter, but such and such a sort of such and such a matter, as shall hereafter more particularly appear.

The various propagation of Plants.

And whereas we said before, that some things seem to be generated of their own accord, which yet are indeed generated out of a Seminal principle, by a living Creature of the same sort; others proceed from Bodies specifically different; we must know, that the Seminal principle is not in all things tied to the same matter; which also appears from Plants, which do not spring of their own accords. For all Plants do not proceed from Seeds peculiarly so called, but some are propagated without Seed by Roots, others by bulbes, others by branches pluckt from the whole, and others by Leaves pluckt off, as the Indian Fig-Tree. And therefore it is no wonder, if the Seminal principle may be preserved entire even in Waters, in Rains, yea and in the dung of Animals, as shall be hereafter more particularly expressed. Yea, and in more Ignoble Animals, the Seed is after the same manner preserved in the Earth and in the Water, as shall hereafter be declared. So that *Aristotle*, 3 *de Generat. Anim. Cap.* 11. said that al things were ful of Souls. For there is scarce any Body from which such Spontaneous Creatures do not arise.

Whether Animals Spring from Bodies imperfectly mixed.

Licetus indeed *Lib.* 2. *de Spont. Viv. Ort. Cap.* 13. holds that such living Things are not bred of Bodies imperfectly mixed: but that must be rightly explained. For sure it is that of Rains, Mists, Dew, sundry kinds of Worms are bred, and experience doth testifie the same. Which though they are imperfectly mixed bodies if they be considered in their own Nature, and in them some Element is predominant, as in Dew and Rain Water: yet among these Bodies other Bodies perfectly mixt are mingled in their smallest Atomes, in which as in Seeds there are the Souls of living Things, and out of which Worms are also Generated afterwards. And therefore Worms are not bred of every Rain, nor of every Dew, but of some only.

The Opinion of Licetus concerning the matter of Spontaneous live things.

Touching this immediate material cause of Spontaneous live Things, *Fortunius Licetus* treats, *Lib.* 2. *de Spont. Vivent. Ort. Cap.* 13, 14, 15, 16. the Sum whereof is this. He saies the Spontaneous and non-Spontaneous Generation of live Things do herein agree, that each is made of a perfectly mixt Body being very near of a temperate complexion, having in it self the last disposition and immediate aptitude to receive a Soul for its Form; and that the preceding disposition or that same privation both in the non-Spontaneous and the Spontaneous generation is nothing else

but

but a temperament just under the degree of the Soul, not having the Soul any waies adjoyned thereto, and that it is a certain degree of heat. But that the difference is herein, that the non-Spontaneous Generation of a living thing is caused by an external agent, first preparing the matter for it self by previous alteration, and afterward when it is prepared, by way of Generation furnishing the same with a Soul: but contrariwise, the Spontaneous Generation of living things is caused by an agent lurking within the matter, prepared by virtue of the Ambient Aire. And that consequently the disposition of the matter subservient to the Spontaneous Original of living things is nothing else but Coction by the Ambient Heat. Moreover he laies down two attributes of the immediate matter of Spontaneous live Things. The first is, that no Animal can be Spontaneously generated, save of a matter which was also before in some sort living, and Animated, either in the rank of Plants or of Animals, whether it be the part of a living Thing, or the Fruit, or the Excrement, or somwhat else belonging thereto; which nevertheless hath not now its Soul any longer as a form, but contains it as a Vessel, forasmuch as it belongs not to the essence of the Carkass wherein it is contained. Another is, that it must be immediately collected and prepared by the heat of the Ambient Aire, that it may put on the Soul and Nature of a living Creature, either of the same sort with the former, or of another sort. For when the matter hath comprehended a natural heat and made it its own, presently it attains a living Nature, and puts on a Soul under the notion of a Form, which before it contained only as a Vessel, being distinct from its Nature.

The opinion of Licetus *examined.*

But in good truth, this Opinion needs a convenient Explication and Limitation. For in the first place, we must needs here repeat what we said before, that there is not one manner of Generation of Spontaneous living Things, but some proceed from a concealed seed of the same kind, as when of a secret Seed a Plant is Generated after Rain, even out of Stones; and others do Spring from dead Carkasses. And therefore, the first attribute of the matter of Spontaneous live Things, *viz.* that it is a Carkass, wherein there is a Soul as in a Vessel, not Animating, doth agree only to the second kind. But if, as he himself holds *Lib.* 3. *Cap.* 117. some powder or Juyce of a plant, having in it a Seminal principle, shal creep into the Chink of some Stone, being brought thither by Rain, there truly a Plant doth not grow out of a Carkass, but out of a Seed of the same sort. Which also happens out of the Dung and excrements of Animals, in which there is either undigested Seed, or some Seminal Juyce. For, as was said before, the Seminal principle is not in al Plants Seed peculiarly so called, which is Generated in a certain part of the Plant endued with a certain Form external, but in some it is diffused through the whole Plant, as in the Willow, and therefore a Willow may be generated by a bough pluckt off from the Tree and Planted in the ground. When therefore of such a Seed or such a Seminal Juyce a Plant is bred, either in the Earth, or in a Stone, or in another Tree, there the plant is not made of a Carkass, but of Seed. Moreover, this also wants explanation; when he writes, that the matter of which such a Generation is made must be very near temperate. For this indeed is true of the efficient cause. For neither a faint heat nor a burning heat can dispose the matter to receive a soul, but it ought to be moderate and of a digestive Nature. But I think it is not necessary, that the matter which is bred by that digestion should be temperate in all. For there is a great difference in respect of temper in the Bodies Generated. For worms are bred of Cole-worts, Wormwood, Pitch wood, Flesh, which have most different Temperaments.

The difference betwixt Spontaneous and non-spontaneous generation.

But as to the difference betwixt Spontaneous and non-Spontaneous Generation, true indeed it is, that in the non-Spontaneous Generation of living Things, or that which is caused by Seed, the matter is Elaborated by the Soul of the living Thing in the Body thereof, and is so prepared, that that which before was not (for neither is the Blood in Animals nor the Alimentary Juyce in Plants Animated) becomes a fit subject for a Soul, and the Soul communicates it self thereto, and then it is called Seed, out of which afterwards when it is cherished by the heat of the Womb or the Sun, or some other thing, and the Latent Soul stirred up, a living Creature of the same kind springs forth. But after this manner the first kind of Spontaneous live Things doth not differ in manner of their Generation from that lately declared. For since, as *Jul. Cæs. Scaliger* saies rightly, *Exercit.* 6. *Sect.* 10. a Tree or

Plant generates when it produces seed, but not when the Tree or Plant Springs up out of the Seed, but then the thing generated which was before imperfect becomes perfect. That Seminal princple, out of which either in the Water or in the Earth or out of Stones, Plants Spring without the culture of man, was Generated in Plants of the same kind, and did for a season lie hid in the Water, Earth, or Stone, til it obtained a fit matter whereof to frame it self a Body. And then if that production of a Plant shall be counted a generation, it is also performed by an internal principle. But in the other kind of Spontaneous living things, when Worms are bred of the Carkasses or Excrements of Plants, the Soul is also present in the Carkas, although not under the notion of a specifical Form, yet realy notwithstanding. But it cannot proceed into act, and exercise the Office of a Form and Soul, nor can it prepare a matter whereto to communicate it self, which is done in Plants and Animals, but there is need of the Heat either of the Ambient Air, or that which arises from putrefaction, that the matter may be fitly prepared and disposed; which when it hath obtained the said form begins to put it self forth, and to exercise the function of a Soul. Also the influx of the Heaven and especially of the Moon, doth not a little assist towards the introduction of such a disposition. For experience teaches that Wood which is cut a little before the new moon is not easily infested with Worms; contrariwise, such as is cut about the full-Moon is most subject to Worms. So out of mud which is dug up about the New-Moon to make furnaces and Hearths, Crickets are easily bred. Now the Bodies in which these Souls lie hid are either the Carkasses of Living things, or parts of the said Carkasses, or the fruits or Excrements of living Things, of which very things *Aristotle* 2 *de Generat. Animal. Cap.* 3. expresly writes, that they have a vital principle; and those Souls did pertain to the disposition of the matter which was the proper subject of that living thing. Hence it is, as *Aristotle* saies well, that every form requires its proper matter, that as the Souls of living things differ, so also those subordinate Forms which constitute the proper matter for every Soul must differ, and therefore every Animal is not bred of every Carkas, or of every part of a living or dead Body, or of every Excrement, but determinate Animals are bred of determinate matter. Of Flesh one kind of Worms and none else is bred; of Cheese Mites proper thereto and no other: of the Leaves of Herbs Palmer-Worms; of the Pine the *Bupestes* and Pityocampe, and no other Worms; of Horse dung a particular sort of Beetles; Long-worms bred in the Guts; Lice and Fleas in the soyl of the Skin; a certain kind of Worms and Beetles under the Shoes, of the filth of the Feet.

The matter of spontaneous live things

Fortunius Licetus indeed, *Lib.* 2. *de Spont. Vivent. Ortu, Cap.* 14. thinks otherwise in this point, (as also hath been said before) and is of opinion that the Soul which he conceives lies hid in the Carkas, as a thing placed in its place, is the same form which was before in the living Creature; and that it remains in the Carkas with some degree of heat, although it belongs not at all to the substance thereof, and that upon a great mutation of the matter it is changed into another sort, and thrust down into a lower degree. But this is a great supposition, that a soul should remain in the Carkas of an Animal after its Death; as also that these Forms should be changed into other species. Nor is it truly credible, that the soul of a Pitch-Tree, or a Pine-Tree should be changed into a worm, or the soul of an Horse into a Wasp. And when Worms are bred of the Excrements of Animals, Whence hath the soul its Original in such a case? Yet we grant, that the soul or seminal principle of such things as have been once generated of their own accord, their body being corrupted, may stick in some matter, and come to live again. So Flies and Frogs may melt in the mud, and of that corrupt matter in the spring time other Flies and Frogs may breed. But all these things shall be hereafter made more manifest, in our Particular Discourse of the Original of Spontaneous live Things, where we shall speake of all the sorts of them.

whether one Form is changed into another.

To conclude therefore this present subject, this I conceive may be most probably held concerning the matter of these kind of Creatures: (since there are two kinds of Spontaneous live Things, as was said before;) that in the former the Seminal matter, as the proper subject of the soul, is communicated from the Generator it self, and that so disposed, that it can retain the soul though it be divided never so smal.

The matter of spontaneous live things

Nor

Nor is this absurd; but that forms may be contained in the smallest Atomes and incomprehensible to the senses, even Metals do shew, which are dissolved into their smallest particles by *Aqua Fortis* and *Aqua Regia*, so as they may be strained through a paper, and yet nevertheless they retain their Essence entire in those smal particles, as by reduction doth appear. Whereof we have spoke at large in the *Third Discourse, Chap. 1. of this Work.* But in the other kind, as in dead Carkasses, the Soul hath that subject wherein it was in the living Body, while it was in place of an immediate matter to the superior Form. But as the Seeds of non-Spontaneous Live Things although they are cast into the ground do not alwaies put forth their inbred Virtue, but are corrupted, sometimes by cold, sometimes by heat, or through want of fit nutriment, and so come to die, or to rest a long time before they put themselves into action; (as many Seeds rest al the Winter in the ground, until by the heat of the Ambient Air they be cherished, and can draw fit nourishment out of the Earth:) so also in those things which are said to arise Spontaneously, the Seminal virtue rests, til it obtain a fit matter out of which to frame it self a Body, and be roused up by the heat of the Ambient Air, and cherished: whence it comes to pass, that Animals which arise of their own accord are not generated in the Winter, unless sometimes under Dung, where the cold cannot come, but in the Spring, Summer and Autumne, *viz.* When by the heat of the Ambient Air caused chiefly by the Sun and Moon, a fit matter is afforded, out of which the Latent Soul may frame it self a Body, and the Soul it self may be set on work. But sometimes this same Seminal Virtue doth quite perish and die. Nor would I have any Man carp at what I have hitherto said and shall hereafter say concerning Souls, and the Seminal Virtue in Atomes and smallest bodies, and charge me as if I held that such souls, because in so many mutations they remain entire, are immortal. For, as the seeds of non-Spontaneous Plants do many times remain long entire, and yet at last die: the same may also happen in the Spontaneous, *viz.* if they meet with some contrary, or the matter be too much divided. Concerning which thing *Francisc. Aguilonius, Lib. 5. de Optic. Propos.* 8. thus writes: although there is no smallest quantity, yet there is the smallest light Natural, that is, a light so weak and thin, that it cannot be made thinner without perishing. After which manner there are also the smallest parts of Natural Bodies; *viz.* which if they be further divided they lose their Form and Essence. And *Propos.* 15. And this Imbecillity of Subsistency is common not only to these qualities which admit the diversity of greater and lesser, but also to al Bodies which vary their magnitude. For as these without some bulk, so the other without some degree of excellency cannot preserve themselves from perishing. For their forces being further attenuated do perish and come to nothing, not destroied by any contrary, but only through want of measure, which is a necessary condition by the irrefragable law of Nature required for the proper maintenance of every one. For that which *Aguilonius* speaks here concerning qualities must also be understood of Forms from whence the qualities do flow.

Forms remain in Atomes.

The Seminal virtue sometimes dies.

Now one there is, who from this Doctrine indeavors to Calumniate me, as if I held that al the Forms of Beasts are separable, and may exsist in the first act, out of their matter, and that therefore they are immortal. For this never came into my mind, but I have held with all Philosophers, that no Form saving the Humane is separable from its matter, but doth perish therewith. Yet this we must hold, that al Forms are not of the same kind, but some so coupled to their Bodies and perfect, that the said Bodies perishing, they also perish, such as are the Forms of an Ox, a Lyon, a Goose, a Crow, and of other perfect Animals. Nor can it be that the Body of a Lyon, an Horse, a Goose, a Crow, being destroyed, the Souls of the said Animals should remain alive. But it is otherwise in plants, wherein the Soul may remain in the Root, Seed, branch, Leaf, yea and as shal be shewn hereafter, in the Juyce. And the same holds in Insects, whose Soul may be preserved in base matter unfurnished with Organs. Yet these Forms cannot exist any where, but though they are not in an Organical Body, yet they are in a proper matter, and indeed the very same which was their matter in an Organical Body. Much less are they immortal, but that matter perishing or being corrupted, they also are abolished, as was lately said.

The souls of Brute Beasts are not immortal.

CHAP.

Chap. 4. *Of the End of Spontaneous Live Things.*

Sundry opinions concerning the end of Spontaneous live-things.

THere remains yet one thing to be explained in General, *viz.* to what end Spontaneous living Things are Generated. For that such Things are not made by Chance or Fortune, was said before. But concerning the end of these things several men are of several minds. Some are of Opinion, that they are therefore generated, that putrid matter might be consumed, and the Air by that means purged. For since out of putrid Bodies many bad exhalations are lifted up, which defile the Air, whereby afterwards more perfect Animals are hurt and become diseased; to prevent this, and to provide for the health of men and other perfect Animals, they hold that Nature produces these petty Creatures, and spends the matter both in their Generation and nutrition. But in good deed, these petty Animals are neither generated of putrid matter as such, nor are they nourished therewith. For although they are made of matter which putrifies, yet are they not made thereof as it is putrid, but rather of the digested and better part thereof being Separated from the putrid. And therefore after the Generation of Worms and such like Animals, putrid matter remains, which pollutes the Air no less then it did before. Nor are these petty Animals which are Generated out of putrifying matter nourished by putrid matter, but seek their food upon other Creatures, as Plants and live Animals. Nor are those Countries or places where these Creatures are plentifully bred, more healthful, but for the most part more unhealthful then other places.

Others are of this Opinion, that as other created things, so these also are made for the sake of Man. But *Julius Cæsar Scaliger*, *Exercit.* 250. *Sect.* 1. doth justly laugh at them who say that Fleas were created for mans sake, to suck out his unprofitable Blood, or that Wig-Lice are sent by Nature to wake us out of our sleep in the nights, that we might pray to God. For are not Dogs also and other brutes ful of Fleas and Lice?

Others, as *Avicenna*, do hold that it is better that Lice should be bred, then that the putrid matter should so remain; and they acknowledg rare workmanship in the structure of such petty Animals. Others conceive such Animals were made for the perfection of the Universe, and that not only perfect Animals, but also such imperfect ones as these do make for the Pulchritude and Integrity thereof. Which *Scaliger* seems to have taught, who *in the place forecited* thus writes: Man for God, and the World is made for man. And *a little after*: Man is the Prince of Animals. Now man should not have been Prince, if he had not been such as he is; *viz.* in the middle. He could not be in the middle, save betwixt extreams. Extreams were therefore made, that he might be in the middest. They were therefore made for the sake of the middlemost. Now if any of the extreams, or of those which are betwixt the middle and the extreams were wanting, there would be a Vacuity or Empty space among the forms. Which would be a greater fault in Nature, then an empty space without a Body. For what is more absurd then a middle without extreams?

The true Opinion.

Which two last Opinions seem not much different, and are convenient enough, if rightly explained. For God the Work-Master of all things would every where discover his Wisdom and power, and therefore was rather willing that living Creatures should be multiplied in Nature, then corrupt and putrid matter; and that the Bodies of perfect Animals when they are corrupted should rather turn to Ignoble Animals, then meer putrid matter. Which kind of Animals are various, yet determinate, and every one according to their kind. For seeing, as *Aristotle* well writes, that as Souls differ one from another in Nobleness and baseness, so also the Nature of that Body wherein they are, and which is the proper subject of every Soul, doth differ: this difference must needs proced from some Form, which although in the living Body of perfect Animals it is instead of matter; yet afterward, the Soul departing, it rouses it self up, and performs that which is in its power to do. Hence, look how many sorts of perfect Bodies there are, so many sorts there are also of Animals arising from them; of which also *Austin*, *Lib.* 12. *de Civitate*

Dei
